Alarcón had achieved a considerable reputation as a journalist and poet when his play *El hijo pródigo* ("The Prodigal Son") was hissed off the stage in 1857. The failure so exasperated him that he enlisted as a volunteer in the Moroccan campaign of 1859–60. The expedition provided the material for his eyewitness account *Diario de un testigo de la guerra de Africa* (1859; "Diary of a Witness of the African War"), a masterpiece in its way as a description of campaigning life. On his return Alarcón became editor of the anticlerical periodical *El Látigo*, but in the years 1868–74 he ruined his political reputation by rapid changes of position. His literary reputation, however, steadily increased. *El sombrero de tres picos*, a short novel inspired by a popular

ballad, is notable for its skillful construction and pointed observation and is a masterpiece of the *costumbrismo* literary genre. Manuel de Falla based his ballet of the same title on the story, and Hugo Wolf wrote an opera so titled. Alarcón's other major novels are *El final de Norma* (1855; *The Last Act of Norma*), *El escándalo* (1875; "The Scandal"), and *El niño de la bola* (1880; "The Lucky Kid").

Alarcos, Battle of (July 18, 1195), celebrated Almohad victory in Muslim Spain over the forces of King Alfonso VIII of Castile. In 1190 the Almohad caliph Abū Yūsuf Ya'qūb forced an armistice on the Christian kings of Castile and Leon, after repulsing their attacks on Muslim possessions in Spain. At the expiration of the truce (c. 1194) Alfonso invaded the province of Seville, prompting Abū Yūsuf to leave his North African capital, Marrakech, with an expedition against the Christians. The Castilians managed to surprise the Muslim advance guard; but, having underestimated the strength of the Almohad army, they were severely beaten by Ya'qūb, who was joined by the cavalry of the Castilian Pedro Fernández de Castro, a personal enemy of Alfonso. The defeat occurred in a battle fought near the fortress of Alarcos (al-Arak in Arabic). Alfonso and his army fled to Toledo and Alarcos, while Ya'qūb returned triumphantly to Seville. There he assumed the title al-Manšūr Billāh ("Made Victorious by God"). For years afterward, even with the support of the king of Aragon, Alfonso was unwilling to confront the Almohads while they marched through his territories, taking Montánchez, Trujillo, Santa Cruz, and Talavera and destroying the vineyards of Toledo.

Alaric (b. c. 370, Peuce Island [now in Romania]—d. 410, Cosentia, Bruttium [now Cosenza, Italy]), chief of the Visigoths from 395 and leader of the army that sacked Rome in August 410, an event that symbolized the fall of the Western Roman Empire.

A nobleman by birth, Alaric served for a time as commander of Gothic troops in the Roman army, but shortly after the death of the emperor Theodosius I in 395, he left the army and was elected chief of the Visigoths. Charging that his tribe had not been given subsidies promised by the Romans, Alaric marched westward toward Constantinople (now Istanbul) until he was diverted by Roman forces. He then moved southward into Greece, where he sacked Piraeus (the port of Athens) and ravaged Corinth, Megara, Argos, and Sparta. The Eastern emperor Flavius Arcadius finally placated the Visigoths in 397, probably by appointing Alaric *magister militum* ("master of the soldiers") in Illyricum.

In 401 Alaric invaded Italy, but he was defeated by the Roman general Flavius Stilicho at Pollentia (modern Pollenza) on April 6, 402, and forced to withdraw from the peninsula. A second invasion also ended in defeat, though Alaric eventually compelled the Senate at Rome to pay a large subsidy to the Visigoths. After Stilicho was murdered in August 408, an antibarbarian party took power in Rome and incited the Roman troops to massacre the wives and children of tribesmen who were serving in the Roman army. These tribal soldiers thereupon defected to Alaric, substantially increasing his military strength.

Although Alaric was eager for peace, the Western emperor Flavius Honorius refused to recognize his requests for land and supplies. The Visigothic chieftain thereupon laid siege to Rome (408) until the Senate granted him another subsidy and assistance in his negotiations with Honorius. Honorius remained intransigent, however, and in 409 Alaric again surrounded Rome. He lifted his blockade after

proclaiming Attalus as Western emperor. Attalus appointed him *magister utriusque militiae* ("master of both services") but refused to allow him to send an army into Africa. Negotiations with Honorius broke down, and Alaric deposed Attalus in the summer of 410, besieging Rome for the third time. Allies within the capital opened the gates for him on August 24, and for three days his troops occupied the city, which had not been captured by a foreign enemy for nearly 800 years. Although the Visigoths plundered Rome, they treated its inhabitants humanely and burned only a few buildings. Having abandoned a plan to occupy Africa, Alaric died as the Visigoths were marching northward.

Alaric II (d. 507), king of the Visigoths, who succeeded his father Euric on Dec. 28, 484.

His dominions comprised Spain (except the kingdom of Galicia), Aquitaine, Languedoc, and western Provence. Alaric, like his father, was an Arian Christian, but he mitigated the persecution of Catholics and authorized the Catholic council at Agde in 506. To provide a law code for his Roman subjects, he appointed a commission to prepare an abstract of Roman laws and imperial decrees. This code, issued in 506, is generally known as the *Lex Romana Visigothorum*, or *Breviary of Alaric*.

Alaric tried to maintain his father's treaty with the Franks, but Clovis, the Frankish king, made the Visigoths' Arianism a pretext for war. In 507 the Visigoths were defeated in the battle of the Campus Vogladensis (Vouillé, or Vouglé, in Poitou). Alaric is said to have been overtaken in flight and killed by Clovis himself.

alarm signal, in zoology, a ritualized means of communicating a danger or threat among the members of an animal group. In many cases the signal is visual or vocal, but some animals—ants, bees, and certain fishes, for example—secrete chemical substances. Alarm communications frequently cross species boundaries. The hawking alarm calls of many small birds are similar and will cause most other birds to take cover. A visual alarm signal, common in mammals, is "flagging," the lifting of the tail to reveal its white undersurface. The white fur shows only in fright situations when the animal raises its tail as it bounds away. Biologists do not agree about the exact meaning of this common mammalian alarm response. While the alarm reaction usually takes the form of a freeze-or-flight response, it may, if the stimulus is within a critical distance, elicit an attack.

Alas (y Ureña), Leopoldo, byname CLARÍN (b. April 25, 1852, Zamora, Spain—d. June 13, 1901, Oviedo), novelist and the most influential literary critic of Spain in the late 19th century. His biting and often bellicose articles, sometimes called *paliques* ("chit-chat"), and his advocacy of naturalism and anticlericalism not only made him the nation's most feared

Alas
Archivo Mas, Barcelona

critical voice but also created many enemies and greatly obscured his fame.

After studying law in Madrid, he went to the University of Oviedo in 1870, received his degree, and took a position in the university as professor of law and political economy, a post he held until his death. His early novels, *La regenta* (1884–85; "The Regent's Wife") and *Su único hijo* (1890; *His Only Son*), are considered two of the greatest Spanish naturalist novels of the century. These books mercilessly depicted the provincial society of Vetusta, an imaginary town modeled upon Oviedo. Although Alas' short stories, as collected in *Cuentos morales* (1896; "Moral Stories") and *El gallo de Sócrates* (1900; "Socrates' Rooster"), are considered inferior to his novels, they are generally more humorous and clearly reflect his wide learning and deep sensibility.

Alaşehir, town, western Turkey. It lies in the Kuzu River valley, at the foot of the Boz Mountain. Founded about 150 BC by a king of Pergamum, it became an important town of the Byzantine Empire. It was not taken by the Ottomans until after all other cities of Asia Minor had surrendered to Ottoman rule. Conquered by Timur (Tamerlane) in 1402, it was recaptured under the Ottoman sultan Murad II (reigned 1421–51). A part of the city was burned down during the Turkish War of Independence (1919–22). Alaşehir lies along the Afyon Karahisar–Manisa–İzmir railway. The surrounding area's products include tobacco, raisins, and fruits. A mineral spring yields a heavily carbonated water that is in great demand in İzmir. Pop. (1997) 44,000.

Alaska, constituent state of the United States of America, lying at the extreme northwest of the North American continent along the tectonically active rim of the North Pacific Ocean. The state is the largest in area and the one with the sparsest population.

A brief treatment of Alaska follows. For full treatment, see MACROPAEDIA: United States of America: *Alaska*.

Facing Siberia across the Bering Strait and Sea to the west, Alaska is also bounded by the Arctic Ocean on the north and northwest, the Pacific Ocean and Gulf of Alaska on the south, and the Canadian Yukon Territory and province of British Columbia on the east. The capital is Juneau. Mainland Alaska extends about 900 miles (1,450 km) from north to south and about 800 miles (1,300 km) from east to west. When the Aleutian Islands and the southeastern Panhandle are included, the east-west extent is about 3,000 miles (4,800 km).

The Indians of Alaska are thought to be descendants of the first North American immigrants who crossed the Bering Land Bridge probably about 40,000 to 15,000 years ago and went on to people the American continents. The Eskimos (Inuit) and Aleuts appear to be descendants of more sedentary Arctic peoples who arrived in Alaska perhaps 8,000 to 3,000 years ago.

The first European settlement was established in 1784 by Russian fur traders at Three Saints Bay on Kodiak Island. The area was administered by the Russian-American Company from 1799 until 1867, when Secretary of State William H. Seward negotiated Alaska's sale to the United States. American settlement was stimulated by significant gold discoveries during the 1880s and 1890s, prompting Congress to establish the Territory of Alaska in 1912. Hostile Japanese activities during World War II necessitated construction of defense facilities as well as the Alaskan (Alcan) Highway. Alaska was admitted to the Union as the 49th state on Jan. 3, 1959. Internal administration of Alaska's land has since been complicated as a result of the retention of vast tracts by the federal government and by the awarding of other vast areas to fulfill the claims of the native peoples.

Physiographically Alaska can be divided into four main regions: (1) the insular and cordilleran south; (2) the interior central plains, and tablelands; (3) the Brooks Range; and (4) the coastal lowland, sometimes called the North Slope, that lies north of the Brooks Range. The Alaska Range rises to the highest point on the continent, Mount McKinley, 20,320 feet (6,194 m). The Aleutian mountain system of the southwest and the St. Elias Mountains and Boundary Range of the southeast are characterized by active volcanoes, earthquakes, and glaciers. The marshy interior of central Alaska is drained by the Yukon and Kuskokwim rivers.

The wide-ranging geographical provinces and great physiographic relief provide much climatic diversity. Relatively mild temperatures, high precipitation, and fog are the predominant features of the maritime climates of the state's southern rim. Continental extremes in the interior, intensified by the long summer days and winter nights, give way to high Arctic (polar) desert conditions in the north.

Alaska, despite being the least populous and least densely populated state in the Union, has experienced an extremely high growth rate, the result of large numbers of youthful immigrants who come seeking economic opportunities. The population increased by 454 percent during the period 1940 to 1980. The median age is only about 26 years. Aboriginal peoples constitute about one-seventh of the population. The Eskimos (Inuit) are the largest native American group (34,000), followed by the American Indians (22,000) and the Aleuts (8,000). More than half of Alaska's inhabitants live in the Anchorage area, about 15 percent around Fairbanks, and about 13 percent in the scattered towns of the southeastern Panhandle region.

The economy of Alaska has become increasingly centred on the oil and natural-gas industry. Since the opening of the Trans-Alaska Pipeline in 1977, Alaska is second only to Texas in production of crude oil. Coal, gold, zinc, silver, copper, and sand and gravel are important mining products. One-third of the labour force is employed in state and federal government agencies and in defense installations. Traditional fishing and forestry industries operate under government regulation to prevent overexploitation. Most cool-weather crops and livestock can be raised, but, because agricultural land is underdeveloped, most food supplies are imported. As a result of increased public awareness and improved transportation facilities, there has been a major upsurge in tourism.

The major transportation links, both internal and external, are by air. The Alaska Marine Highway operates ferry service among most of the coastal communities. The cities of the south-central region are linked by road to the Alaskan Highway, and thus to western Canada and the 48 coterminous states.

The University of Alaska statewide system of higher education has urban centres at Fairbanks, Anchorage, and Auke Lake (Juneau), as well as several community colleges. Alaska's heritage is culturally removed from the American mainstream, centring on the arts and crafts of its native peoples and the remnants of Russian settlement. Much of this vast northern land remains as America's last virgin wilderness, endowed with abundant natural resources, and is often perceived to have a dramatic beauty and a special national character. Area 591,004 square miles (1,530,700 square km). Pop. (2000) 626,932.

Alaska, Gulf of, broad inlet of the North Pacific on the south coast of Alaska, U.S. Bounded by the Alaska Peninsula and Kodiak Island (west) and Cape Spencer (east), it has a surface area of 592,000 sq mi (1,533,000 sq km). The coast is deeply indented by fjords and other inlets, including Cook Inlet and

Prince William Sound (on either side of the Kenai Peninsula). The gulf receives the Susitna and Copper rivers. Large glaciers cast off huge icebergs, which are taken out to sea by the Alaska Current. Rising from the gulf's shores in Alaska are the high Chugach, Kenai, Fairweather, and St. Elias mountains. Ports along the gulf include Anchorage, Seward, and North America's northernmost ice-free harbour, Valdez, which is the trans-Alaskan pipeline terminal. Oil has been found along Cook Inlet and beneath Controller Bay. The British navigator Captain James Cook entered the gulf in 1778 and proceeded as far north as Prince William Sound.

Alaska blackfish (species *Dallia pectoralis*), Arctic freshwater fish, assigned by some authorities to the family Umbridae but by others to the separate family Dallidae. The fish is about 20 cm (8 inches) long, with a dark, streamlined body, protruding lower jaw, and two large opposed fins near the tail. Locally important as a food fish, it lives in shallow streams and ponds of North America and Siberia. Although it is said to withstand being frozen solid, this has never been substantiated.

Alaska Current, surface oceanic current, a branch of the West Wind Drift that forms a counterclockwise gyre in the Gulf of Alaska. In contrast to typical sub-Arctic Pacific water, Alaska Current water is characterized by temperatures above 39° F (4° C) and surface salinities below 32.6 parts per thousand.

Flow velocities at a depth of 16 feet (5 m) have been reported to be as high as 1.7 knots (1.9 miles per hour) for the southern portion of the current. Volume transport is estimated to be in the range of 350,000,000 to 700,000,000 cubic feet (10,000,000 to 20,000,000 cubic m) per second.

Alaska Highway, formerly ALCAN HIGHWAY, road (1,523 miles [2,451 km] long) through the Yukon, connecting Dawson Creek, B.C., with Fairbanks, Alaska. It was previously called the Alaskan International Highway, the Alaska Military Highway, and the Alcan (Alaska-Canadian) Highway. It was constructed by U.S. Army engineers (March–November 1942) at a cost of \$135 million as an emergency war measure to provide an overland military supply route to Alaska. The Canadian part (1,200 miles [1,930 km], mostly gravel) was turned over to Canada in 1946. A scenic route open all year round, it joins highways to Edmonton and Prince George (in the south) and highways to Valdez, Anchorage, Seward, and Haines (in the north).

Alaska Peninsula, stretch of land extending southwest from mainland Alaska, U.S., for 500 miles (800 km) between the Pacific (southeast) and Bristol Bay, an arm of the Bering Sea. The volcanic Aleutian Range runs along its entire length. It is the site of the Katmai National Park and Preserve, the Aniakchak National Monument and Preserve (*qq.v.*), and the Becharof, Alaska Peninsula, and Izembek National wildlife refuges.

Alaska Purchase (1867), acquisition by the United States from Russia of 586,412 square miles (1,518,800 square km) of land at the northwestern tip of the North American continent.

William Henry Seward, secretary of state under President Andrew Johnson, had as early as 1860 dreamed of acquiring Alaska. The territory was considered an economic liability by the Russians, and in December 1866 Baron Eduard de Stoeckl, Russian minister to the United States, was instructed to open negotiations with Seward for its sale. On March 29, 1867, Stoeckl and Seward completed the draft of a treaty ceding Russian North America to the United States, and the treaty was signed early the following day. The price—\$7,200,000—amounted to about two cents per acre.

Few Americans, however, viewed the purchase as a bargain, and Seward was vilified in the press. "Seward's Icebox" and "Seward's Folly" were the two most popular names for the Alaska Purchase, and ratification by the Senate and funding by the House of Representatives seemed in jeopardy as a result of the public outrage. The treaty was submitted for ratification on March 30. Senator Charles Sumner spoke in its favour, and the treaty was passed on April 9. The House passed the necessary appropriation on July 14, 1868. Extensive propaganda campaigns and judicious use of bribes by Stoeckl secured the required votes in each house of Congress.

Alaska Range, segment of the Pacific Coast Ranges that extends generally northward and eastward in an arc for about 400 miles (640

The Muldrow Glacier in the Alaska Range
Charles J. Oitt—Photo Researchers/EB Inc

km) from the Aleutian Range to the Yukon boundary in southern Alaska, U.S. Mount McKinley (20,320 feet [6,194 m]), near the centre of the range, in Denali National Park, is the highest point in North America. Many nearby peaks exceed 13,000 feet (3,960 m), including Mounts Silverthrone, Hunter, Hayes, and Foraker. Drained by the Yukon River (north) and the Pacific Ocean (south), the mountains separate the interior tundra prairie from the Pacific coastal region. The peaks present many challenges to climbers, while tourists are attracted by the enormous glaciers and Arctic scenery. The range is crossed at Isabel Pass by the trans-Alaskan oil pipeline en route to its southern terminal at Valdez.

Alaskan brown bear, race or subspecies of grizzly bear (*q.v.*).

Alaskan king crab: *see* king crab.

Alaskan Malamute, sled dog developed by the Malemiut, an Eskimo group from which it takes its name. The Alaskan Malamute is

a strongly built dog, with a broad head, erect ears, and a plumelike tail carried over its back. Its thick coat is usually gray and white or black and white, the colours frequently

forming a caplike or masklike marking on the head. The Alaskan Malamute stands about 23 to 25 inches (58 to 64 cm) high and weighs 75 to 85 pounds (34 to 39 kg). Characteristically loyal and friendly, it has been used to haul freight on sleds and has served on expeditions to the Antarctic.

Alatri, town, Frosinone *provincia*, Lazio (Latium) *regione*, central Italy. It lies in the Cosa River valley, at 1,647 feet (502 m) above sea level, just north of Frosinone city. Said to have been founded in 1830 BC as Alatrium (mentioned by the Greek geographer Strabo), it belonged to the confederation of the Hernici, an ancient people of Italy, and later passed under the dominion of Rome (306 BC).

Archaeologically the town is of significance for its great belt of cyclopean walls (6th century BC) that enclose the superb trapezoid Pelasgian (pre-Hellenic) acropolis, the walls of which are almost intact. The outer circle of walls, about 2.5 miles (4 km) long, supplemented at intervals by fine medieval towers, is penetrated by three massive gates. Other important buildings are the Casagrandi Palace (now the civic museum), the bishop's palace, the episcopal seminary, and the cathedral. Although it is a resort with rail connections to Rome and Naples, Alatri is also an agricultural and manufacturing centre. Pop. (1989 est.) mun., 24,687.

Ala'ud'din (d. c. 1564, probably Acheh, Sumatra [now in Indonesia]), sultan of the Malay kingdom of Johore from 1528. He is sometimes considered the cofounder of the kingdom with his father, Mahmud Shah, the last sultan of Malacca, who established Johore on the island of Bintang (southeast of Singapore) in 1512–13. Sometime after his father's death (1528), Ala'ud'din moved his capital to Johore Lama. The Achinese sacked Johore Lama in 1564 and took Sultan Ala'ud'din prisoner to die in Acheh (one account, however, gives Johore Lama as the place of death).

Alaungpaya (Burmese: "The Victorious"), also spelled ALAUNG PHRA, ALOMPRA, or AUNGZEYA (b. 1714, Moksobomyo [Shwebo], Myanmar—d. April 13, 1760, Kin-ywa, Martaban province, Myanmar), king (1752–60) who unified Myanmar (Burma) and founded the Alaungpaya, or Konbaung, dynasty, which held power until the British annexed Upper (northern) Burma on Jan. 1, 1886. He also conquered the independent Mon kingdom of Pegu (in the Irrawaddy River delta).

Of humble origins, Alaungpaya was a village headman from the small town of Moksobomyo (present-day Shwebo), north of Ava, the Myanmar capital, when in April 1752 Binnya Dala, the Mon king of Pegu, captured Ava and put an end to Myanmar's ruling Toungoo dynasty. Refusing to become his vassal, Alaungpaya organized a resistance movement. Claiming descent from a 15th-century Myanmar king, he established a new Myanmar capital at Moksobomyo. In 1753 he recaptured Ava and went on the offensive in southern Myanmar. In 1755, at the end of a lightning campaign into the Mon country, he founded a new port, to be called Yangôn (Rangoon), at the site of the Mon fishing village of Dagon. In 1757 he captured the city of Pegu, and took Binnya Dala prisoner. Alaungpaya established effective control over the whole area previously under the rule of the Toungoo dynasty.

Because the French had allied themselves with the Mon, Alaungpaya was eager to gain British support. In 1757 he concluded a treaty with the British East India Company, granting it generous trade concessions. But the company, at war with the French in India, was

unwilling to involve itself on a second front in Myanmar. In October 1759 the king's troops massacred British merchants at Negrais who were suspected of aiding a local revolt. After that action, relations between Britain and Myanmar were suspended.

Alaungpaya's last campaign was an invasion of Siam (Thailand). He led an army through the town of Tavoy southward to Tenasserim and then northward to Ayutthaya (Ayuthia), the Siamese capital, which he surrounded in April 1760. During the siege he was wounded, and he died while his army was in retreat to Myanmar.

Alaungpaya DYNASTY, also called KONBAUNG, the last ruling dynasty (1752–1885) of Myanmar (Burma). The dynasty's collapse in the face of British imperial might marked the end of Myanmar sovereignty for more than 60 years. (Some authorities limit the name Konbaung dynasty to the period beginning with King Bodawpaya in 1782 and continuing to 1885.) The Alaungpaya dynasty led Myanmar in an era of expansionism that was only brought to an end by defeat in the First Anglo-Burmese War of 1824–26.

By the 18th century Myanmar under the Toungoo dynasty (1486–1752) was fragmented: the Shan States to the north and east of Ava were as much Chinese as Burmese, while in the southeast the Mon people's separatism had been rekindled by 1740. In 1752 Alaungpaya, a village headman in Shwebo (then called Moksobomyo; near Mandalay), organized an army and led a successful attack against the Mon rulers of the southern part of Myanmar. Alaungpaya led his armies southward, crushing all local resistance. Aware that his power rested on his ability to centralize his kingdom, Alaungpaya forced the rulers of the Shan States to accept his suzerainty. Advancing farther eastward, he attacked the Siamese kingdom of Ayutthaya (now in Thailand) but was forced to withdraw and was mortally wounded (1760) during his retreat.

In 1764 Hsinbyushin, third king of the dynasty, restored order and renewed the conquest of Ayutthaya, which he reduced to ruins in 1767 but which he was unable to hold for long. Hsinbyushin's armies ranged far into the Shan and Lao states and the Manipur kingdom of India and four times defeated invasions of Myanmar by the Chinese. Hsinbyushin, intent upon pacifying the southern areas, was stymied in 1776. Bodawpaya (reigned 1782–1819), sixth king of the dynasty, was committed to the reconquest of Ayutthaya and mounted a number of unsuccessful campaigns against the Siamese. Bodawpaya also moved the capital to nearby Amarapura.

Under Bagyidaw (reigned 1819–37), Bodawpaya's grandson and successor, Myanmar met with defeat at the hands of the British in the First Anglo-Burmese War (1824–26). During the succeeding years there was a gradual erosion of Myanmar territories as well as a weakening of authority. Tharrawaddy (reigned 1837–46) and his son, Pagan (1846–53), both weak kings, accomplished little in foreign or domestic affairs, allowing Great Britain to gain control of all southern Myanmar in the Second Anglo-Burmese War (1852). Under Mindon, an enlightened ruler (1853–78), Myanmar tried unsuccessfully to rescue its prestige. Friction developed between Mindon and British Burma, principally because Mandalay (Mindon's new capital) resented the British presumption of suzerainty. Finally, when Mindon's younger son Thibaw ascended the throne in 1878, only an excuse was needed for Britain's total annexation of Burma; the Third Anglo-Burmese War (1885) accomplished this objective, ending the Alaungpaya, or Konbaung, dynasty on Jan. 1, 1886.

Álava, *provincia*, northern Spain. Álava is the southernmost of the three Basque Country *provincias* of northern Spain and is located mainly on the southern slope of the Pyrenees Range. It is bounded by the Ebro River (southwest) and surrounds the enclaves of Treviño and Orduña belonging to Burgos and Vizcaya *provincias*, respectively. Álava has an area of 1,176 square miles (3,047 square km). Formerly a lordship, it was incorporated into Castile in 1332. With Guipúzcoa and Vizcaya, it became one of the three component *provincias* of the Basque Country *comunidad autónoma* ("autonomous community") in 1980.

The *provincia* consists of three distinct regions. In the northern woodlands sector, interspersed with isolated farms, lakes, and the valleys of the Urquiola, Bayas, and Omecillo rivers, the production of corn (maize) is the chief economic activity. The central heartland, as the Basque name Álava (*araiar*, "set among the mountains") implies, is an intermontane basin (of about 1,500 feet [460 m] elevation) called the Vitoria Plain. Chief crops cultivated on the plains area are wheat, barley, and oats; sugar beets predominate around the provincial capital, Vitoria (*q.v.*). The southern Álavese Rioja, separated from the Vitoria Plain by the Cantabrian and Toloño mountains, is known for its vineyards, orchards, and olive groves. Industry (powered by mostly hydroelectric dams) is concentrated in Vitoria. Pop. (1988 est.) 272,563.

Consult the INDEX first

'Alawite, Arabic 'ALAWĪ, plural 'ALAWĪYAH, also called NUṢAYRĪ, plural NUṢAYRĪYAH, or NAMĪRĪ, plural NAMĪRĪYAH, or ANSARĪ, plural ANSARĪYAH, any member of a minority sect of Shī'ite Muslims living chiefly in Syria.

The roots of 'Alawism lie in the teachings of Muḥammad ibn Nuṣayr an-Namirī (fl. 850), a Basran contemporary of the 10th Shī'ite imam, and the sect was chiefly established by Husayn ibn Ḥamdān al-Khaṣībī (d. 957 or 968) during the period of the Ḥamdānid dynasty (905–1004), at which time the 'Alawites had great influence in Aleppo. With the fall of Shī'ite rule, however, the 'Alawites, with other Shī'ites, became the victims of persecution. They were ill-treated by waves of Crusaders, by Mamlūks, and by Ottoman conquerors, in addition to fighting a number of internecine wars.

Considered by many Muslims to be heretics, the present-day 'Alawites obtained a legal decision about their status as Muslims from the Lebanese leader of the Ithnā 'Ashariyah (Twelver) sect of Shī'ite Islām. The 'Alawite sect has become politically dominant in Syria, particularly since 1971, when Ḥafiz al-Assad, an 'Alawite, was elected president of the country. The sect is predominant in the Latakia region of Syria, and it extends north to Antioch (Antakya), Turkey. Many 'Alawites also live around or in Ḥimṣ and Ḥamāh. They are second in number within Syria to the Sunnite sect, which makes up about three-fourths of the Muslim population of mostly Muslim Syria.

The name 'Alawī is more generally used to refer to all the groups affiliated with one of the 'Alis; thus the Muslims usually refer to the Syrian 'Alawites as Nuṣayriyah, or Namiriyah. Though well established in Syria since the 12th century, the 'Alawites were not able to fully adopt the name 'Alawī until 1920, the time of French occupation of the area.

The basic doctrine of 'Alawite faith is the deification of 'Ali. He is one member of a trinity corresponding roughly to the Christian Father, Son, and Holy Spirit. 'Alawites interpret the Pillars of Islām (the five duties required of every Muslim) as symbols and thus do not practice the Islāmic duties. They celebrate an eclectic group of holidays, some

Islāmic, some Christian, and many 'Alawite practices are secret. They consider themselves to be moderate Shī'ites, not much different from the Twelvers.

ālaya-vijñāna (Sanskrit: "store of consciousness"), key concept of the Vijñānavāda ("Consciousness-affirming") school of the Mahāyāna Buddhist tradition. Since that school maintains that no external reality exists, while retaining the position that knowledge, and therefore a knowable, exists, it assumes that knowledge itself is the object of consciousness. It therefore postulates a higher storage consciousness, the final basis of the apparent individual. The universe consists in an infinite number of possible ideas that lie inactive in storage. That latent consciousness projects an interrupted sequence of thoughts, while it itself is in restless flux until the karma, or accumulated consequences of past deeds, is destroyed. That storage consciousness contains all the impressions of previous experiences (*vāsanās*, "perfumings"), which form the germs (*bija*) of future karmic action, an illusive force that creates categories that are in fact only fictions of the spirit. That illusive force (*maya*) determines the world of difference and belongs to man's nature, producing the erroneous notions of an I and a non-I. That duality is conquered only by enlightenment (*bodhi*), which transforms a person into a buddha.

alb, liturgical vestment worn in some services by Roman Catholic officiants, some Anglicans, and some Lutherans. A symbol of purity, it is a full-length, long-sleeved, usually white linen tunic secured at the waist by a cord or belt called a cincture. The equivalent vestment in the Eastern churches is the sticharion.

Linen alb from Germany, 13th century; in the Bavarian National Museum (Bayerisches Nationalmuseum), Munich
By courtesy of the Bayerisches Nationalmuseum, Munich

Derived from the long white tunic (*tunica alba*, or *linea*) commonly worn in the Greco-Roman world, the alb was retained by the Christian clergy as a vestment after secular styles began changing in the 6th century AD. In the 10th century the plain alb was decorated with embroidery on the hem and cuff, and it was later decorated with four or five rectangular patches of embroidery called *parures*, *apparels*, or *orphreys*. Apparels became less common in the 16th century and were replaced by lace, which eventually covered most of the garment. In the 20th century, with the Roman Catholic liturgical renewal, the plain white linen alb came back into use.

Alba, the kingdom formed by the union of the Picts and Scots under Kenneth I MacAlpin in 843. Their territory, ranging from modern Argyll and Bute to Caithness, across much of southern and central Scotland, was one of the few areas in the British Isles to withstand

the invasions of the Vikings. The ancient link with Ireland (from which the Celtic Scots had emigrated) was broken as a cordon of Scandinavian settlements were established in the Western Isles and Ireland. With southern England also conquered by the Norsemen and Danes, Alba was left isolated. With the withdrawal of the Norsemen, England, under the English, then launched invasions against Alba but were ultimately repelled by Malcolm II at the Battle of Carham (1016/18). When Malcolm's grandson and successor Duncan I came to the throne in 1034, he united Alba with Strathclyde, Cumbria, and Lothian. Thereafter, the name Alba began to fade away; and every king, at least in retrospect, was normally styled "king of Scots." The first extant recorded use was by Duncan II, the "*Rex Scotie*," in 1094.

Alba, town, Cuneo *provincia*, Piedmont *regione*, northwestern Italy. It lies along the Tanaro River southwest of Turin. It occupies the site of the Roman Alba Pompeia, which was probably founded by Pompeius Strabo (consul, 89 BC) when he constructed the road from Aquae Statiellae (Acqui Terme) to Augusta Taurinorum (Turin). The town became an episcopal see dependent on Milan in the 4th century. The San Lorenzo Cathedral (1486) and the civic museum, with collections of Roman and prehistoric relics, are notable. An agricultural trade centre specializing in wines and white truffles. Alba has a school of viticulture and light industry. Pop. (1990 est.) mun., 30,363.

Alba, *judet* (county), western Romania, occupying an area of 2,406 square miles (6,231 square km). The Western Carpathians rise above the settled areas in intermontane valleys. The county is drained westward by the Mureş River and its tributaries. Neolithic artifacts have been found at Alba Iulia (*q.v.*; the county capital) and other sites in the *judet*. A Celtic community (3rd century BC) was situated at Aiud, and remnants of Daco-Roman villages have been found at Aiud, Sebeş, and Alba Iulia. Vineyards are worked in the Mureş River valley. Corn (maize) is grown in southern areas, and wheat is cultivated in the north. Mercury, gold, silver, and other nonferrous metals are mined in the western portion of the district, and basalt is quarried. Industries located in the cities and larger towns produce machinery, chemicals, textiles, paper, and leather and wood products. Highways and railway lines parallel the district's river courses, extending through Alba Iulia, Cîmpeni, and Aiud. Pop. (1987 est.) 425,903.

alba (Provençal: "dawn"). French *AUBE*, or *AUBADE*, in the music of the troubadours (*q.v.*), the 11th- and 12th-century poet-musicians of southern France, a song of lovers' parting at dawn or of a watchman's warning to lovers at dawn. It sometimes takes the form of a dialogue between watchman and lover. Examples for which music also survives include "Reis glorios" by Guiraut de Bornelh and the anonymous "Gaité de la tor." The German counterparts of the troubadours, the *Minnesingers*, also used the form, calling it *Tagelied* ("day song").

Alba, Fernando Álvarez de Toledo y Pimentel, 3^{er} duque de (3rd duke of). Alba also spelled *ALVA* (b. Oct. 29, 1507, Piedrahita, Old Castile, Spain—d. Dec. 11, 1582, Lisbon [Portugal]), Spanish soldier and statesman famous for his conquest of Portugal (1580) and notorious for his tyranny as governor-general of the Netherlands (1567–73). In the Netherlands he instituted the Council of Troubles (nicknamed the Council of Blood), which set aside local laws and condemned thousands.

Alba was born into a rich family with a long record of service to the kings of Castile. In 1524 he joined the Spanish forces fighting the French at Fuenterrabía and so distinguished

himself that he was appointed governor of the town after its capture. Subsequent campaigns made him the most thoroughly professional military commander of his age. He insisted on rigorous training and discipline for his troops and developed the tactical use of firearms. He was a master of logistics, and his greatest asset was an unshakable self-confidence that enabled him to resist the rash counsels of his more impetuous officers. He commanded a part of Emperor Charles V's army in the

Alba, oil painting by Sir Antony More, 1549; in the Musées Royaux des Beaux-Arts, Brussels

By courtesy of the Musées Royaux des Beaux-Arts, Brussels

successful expedition against Tunis in 1535, and in 1546–47 he commanded the imperial armies against the German Protestant princes of the Schmalkaldic League. By his victory at Mühlberg (April 24, 1547) Alba placed Charles V at the pinnacle of his power. Alba was made commander in chief of the imperial forces in Italy in 1552 and, after the succession of Philip II of Spain, he was made viceroy of Naples (1556). In the last phase of the Franco-Spanish War in Italy, he outmaneuvered the Duke of Guise and forced Pope Paul IV to come to terms with Spain (1557).

After the Peace of Cateau-Cambrésis (1559), Alba became one of Philip II's two leading ministers. Charles V, an excellent judge of character, in a secret testament of 1543 had recommended Alba to his son Philip as a reliable adviser in all military matters and in affairs of state but otherwise not to be trusted, for he was enormously ambitious, wished to command everything, and would employ any means to achieve his ambitions. Philip II therefore never fully trusted Alba. He did, however, summon him regularly to the Council of State, where, in opposition to the other of the king's chief advisers, Ruy Gómez de Silva, Alba pressed for a vigorous foreign policy.

As early as 1563 Alba advised the king to cut off the heads of the leaders of the aristocratic opposition in the Netherlands. But if this should not be immediately possible, he remarked, the king should dissemble now and execute them at a more opportune moment. In 1565 Philip sent him, together with his queen, Elizabeth of Valois, to meet Elizabeth's mother, Catherine de Médicis, regent of France. Alba managed to hold his own against that virtuoso politician, blocking Catherine's efforts to arrange a Spanish marriage for her son to which Philip II did not wish to commit himself. Understandably, he did not succeed, in his turn, in committing Catherine to a more active anti-Huguenot policy with Spanish assistance. The later Protestant accusation that at Bayonne he and Catherine planned the St. Bartholomew's Day Massacre of Protestants in 1572 has no basis in reality.

Following the popular movements of 1566, Philip sent Alba to the Netherlands with a large army to punish the rebels, root out heresy, and reestablish the king's shaken authority (August 1567). Alba arrested Lamoraal, graaf van Egmond, and Philips van Montmorency, graaf van Hoorne, the rather halfhearted leaders of the opposition, and set up a new court, the Council of Troubles (soon to be known as the Council of Blood). This court set aside all local laws and condemned some 12,000 persons for rebellion, many of whom, however, had fled the country. Alba allowed himself to be involved in a trade war with England that caused great damage to Netherlands commerce. Worst of all, he mishandled the plan to place his government on a stable financial basis, independent of the estates. He proposed a 10 percent tax on all sales (the "10th penny") and a 1 percent property levy. But the States General would agree only to the property tax and made counter offers, in place of the "10th penny." In the face of the opposition of the lower classes and the clergy, Alba had to modify the tax progressively. In the end it was never collected. While Alba's "10th penny" certainly helped to rouse the country against Spain, it did not cause its economic ruin, as once was thought.

In 1572 the Gueux—Dutch guerrillas—captured most of Holland and Zeeland, and the Prince of Orange and his brother Louis of Nassau invaded the Netherlands from Germany and France, respectively. Alba defeated the land invasions and recaptured part of Holland, where his troops committed terrible atrocities. Short of money and lacking adequate sea power to oppose the fleet of the Gueux, he failed to recapture the remainder of Holland and Zeeland.

Alba's failure and the intrigues of the Gómez party at court induced Philip to recall him (1573). In 1579 Alba was placed under house arrest on his estates after his son had married against the king's wishes. In 1580 Cardinal Granvelle persuaded Philip to let Alba command the invasion of Portugal. Within a few weeks, in one of his most brilliant campaigns, Alba took Lisbon. Yet he never regained Philip's favour.

In Protestant countries Alba's name became a byword for cruelty and religious tyranny. Outside Spain he has never been forgiven for his disregard of legality, for his policy of terror, and for the outrages committed by his troops in the Netherlands and Portugal. Of the responsibility for these acts he cannot be exonerated, nor were they universally accepted even by Roman Catholic opinion in the 16th century. In Spanish history Alba is important as a representative of the old nobility, independent and proud of its rights and privileges yet willing to serve as the champion and defender of an absolute monarchy. (H.G.K.)

BIBLIOGRAPHY. William S. Maltby. *Alba* (1983).

Alba Fucens, modern *ALBE*, ancient fortified town at the foot of Mount Velino, Italy. It was originally a town of the ancient Marsi people but was occupied by a Latin colony about 303 BC. It was situated on a hill with three distinct summits, all of which were enclosed within the walls. Its strong position made it important in the Social War and in the civil wars of the 1st century BC; state prisoners of the Romans were often held there.

Much survives of the main circuit of walls; the gateways, which also remain, were so placed as to expose the right side of an attacking force. The acropolis in the northern corner had a separate line of walls, forming an independent stronghold.

Alba Iulia, German *KARLSBURG*, Hungarian *GYULAFEHÉRVÁR*, city, capital of Alba *judet* (county), west-central Romania. It lies along

the Mureş River, 170 miles (270 km) northwest of Bucharest. One of the oldest settlements in Romania, the site was selected by the Romans for a military camp. The remains of Apulum, an important city in Roman Dacia mentioned by Ptolemy in the 2nd century BC, are 6 miles (10 km) from Alba Iulia, and the Regional Museum has a rich collection of Roman antiquities. From the 9th to the 11th century the town bore the Slavic name Bălgrad. The Roman name was first documented in 1097, and the use of Alba Iulia in Latin documents ensured the survival of the name.

In the 16th and 17th centuries Alba Iulia became the capital of the principality of Transylvania. In 1599 Michael the Brave (Mihai Viteazul) proclaimed himself prince of Walachia, Transylvania, and Moldavia at Alba Iulia—achieving for the first time the union of the three great provinces of Romania. The town became a centre of Romanian nationalism and an important Romanian-language printing centre. It was at Alba Iulia that the union of Transylvania with Romania was pronounced on Dec. 1, 1918; Romania's King Ferdinand and Queen Marie were crowned in the Orthodox cathedral in 1922.

The city also has a 13th-century Roman Catholic cathedral (Romanesque), an 18th-century fortress, and the Batthyáneum Library, founded in 1794 by Ignatius Batthyány, a Catholic bishop, and containing many incunabula and old manuscripts of great value, notably the *Codex Aureus* from the 8th century. Industries in Alba Iulia include leather-working and food processing and the production of footwear, construction materials, and wine. Pop. (2002) 66,369.

Alba Longa, ancient city of Latium, Italy, in the Alban Hills about 12 miles (19 km) southeast of Rome, near present Castel Gandolfo. Tradition attributes its founding (c. 1152 BC) to Ascanius, the son of the legendary Aeneas, thus making it, according to legend at least, the oldest Latin city, which in turn founded others, including Rome. Alba Longa headed a Latin league of uncertain extent until destroyed about 600 BC by Rome. The name Albanum, from about 150 BC until the time of the emperor Constantine I the Great, meant the imperial villa in the Alban territory. The emperors formed a single estate out of a considerable part of this district, including apparently the whole of the lake, and Domitian was especially fond of it. The imperial villa occupied the site of the present Villa Barberini at Castel Gandolfo, and considerable remains still exist.

Albacete, *provincia* in the *comunidad autónoma* ("autonomous community") of Castile-La Mancha, southeast-central Spain. It occupies the southeastern end of the Meseta Central (plateau). Albacete is the driest interior province of the Iberian Peninsula, with as little as 2 inches (50 mm) annual rainfall in some areas. The south is mountainous or hilly and is crossed by the Júcar and Segura rivers, which are the chief local sources of power and water for irrigation. The Sierra de Alcaraz rises in the west.

Albacete is a stock-raising province, but barley growing is increasing steadily, with a corresponding decline in livestock, though sheep raising remains important. Cheese is sent to all parts of Spain; vines, which have suffered much from phylloxera, and olives and apricots are cultivated. Other products include saffron, esparto grass, and pine lumber.

Industry is concentrated in the provincial capital, Albacete (food and leather processing), where a large proportion of the province's population lives, and in such towns as Almansa, Hellín, and La Roda. Service industries have become very important. Much of

the province is accessible only by road, although there are good railway connections with Madrid and Alicante. Area 5,762 square miles (14,924 square km). Pop. (2001) 364,835.

Albacete, capital of Albacete *provincia*, Castile-La Mancha *comunidad autónoma* ("autonomous community"), southeast-central Spain. Albacete is located in the historic La Mancha region, on the Don Juan River at its juncture with the María Cristina Canal. Of Moorish origin (Arabic: Al-Basit), it was the scene of two battles between Christians and Moors, in 1145 and 1146. Refounded in 1365 as Albacete, it played an important part in the War of the Spanish Succession; the Battle of Almansa was won near there by King Philip V in 1707. Development came only after the construction in the 19th century of the María Cristina Canal, which drained malarial swamps to the south.

Albacete is divided into the upper town (Alto de Villa), or old quarter, and the lower, modern town. Landmarks include the 16th-century San Juan Bautista Cathedral (restored after a fire in 1936). The city is now a market centre for agricultural produce (fruit and saffron). Industry is primarily based on agriculture but includes light metallurgical and textile manufacture. Knives and daggers (now chiefly souvenirs) from Albacete are known throughout Spain. The growing service industry includes education and the military. A provincial museum displaying the work of regional and local artists opened in 1978. Pop. (2001) 148,934.

albacore, also spelled ALBICORE (species *Thunnus alalunga*), large oceanic fish noted for its fine flesh. The bluefin tuna (*T. thynnus*) is also sometimes called albacore. *See* tuna.

Albalag, Isaac (fl. 13th century AD, northern Spain or southern France), Jewish philosopher who rendered a Hebrew translation of parts of the *Maqāsid al-falāsifah* ("Aims of the Philosophers"), a review of doctrines of earlier thinkers by the Arabic philosopher al-Ghazālī, to which Albalag added his own views and comments. In defending philosophy against the accusation that it undermined religion, Albalag espoused the doctrine of the "double truth"—prophetic truth known through revelation and philosophic truth arrived at through reason. He believed philosophy and religion were in fundamental agreement but that religion was for the masses and philosophy for the few. He felt that philosophy need not bow to revelation when the results of its speculations disagree with revelation.

Alban, SAINT (fl. c. 3rd century AD, traditionally at Verulamium, Britain; feast day June 22), first British martyr.

According to the historian Bede, he served in the Roman army and was converted to Christianity by a fugitive priest whom he sheltered and with whom he exchanged clothes, so that he was martyred in the priest's place (c. 304; other dates suggested by scholars are c. 254 or c. 209). His feast day is commemorated on June 17 in the Church of England, apparently because of misreading of the Roman numerals XXII. His tomb was venerated, and a church had been built on the site as early as 429. Later, the Abbey of St. Albans was founded there, and around it grew the town of St. Albans.

Albán, Monte (Mexico): *see* Monte Albán.

Alban Hills, Italian COLLI ALBANI, or MONTI ALBANI, area of extinct volcanoes in the Lazio (Latium) *regione* of central Italy, southeast of Rome. The hills consist of an outer circle, 6–8 miles (10–13 km) in diameter, rising to 3,113 feet (949 m) at Mount Cavo, and an inner crater rim, about 1.5 miles (2 km) across, rising to 3,136 feet (956 m) at Mount Faete. Lakes Albano and Nemi occupy two of the craters. Even before the emergence of Rome

as a great power, the Alban Hills were a place sacred to the people of Latium. Roman roads, temples, villas, and theatres are still partly preserved there. Because of their coolness in summer and the absence of malaria, the hills for centuries have been a favourite summer resort of Romans. The Alban vineyards produce the popular wines known as Castelli Romani (after the towns of the district). An electric suburban railway connects Rome with the hill retreats of Frascati, Grottaferrata, Albano, Velletri, Genzano, and Castel Gandolfo (the papal summer residence).

Albani, Francesco, Albani also spelled ALBANO, or L'ABANE (b. March 17, 1578, Bologna, Papal States [Italy]—d. October 1660, Bologna), Italian painter, one of the 17th-century Bolognese masters trained in the studio of the Carracci. He assisted Guido Reni in a number of major decorative cycles, including that of the Chapel of the Annunciation (1609–12) in the Quirinal Palace and the choir (1612–14) of Santa Maria della Pace.

Albani lived for several years in Rome, where he had his own academy. There he painted, after the designs of Annibale Carracci, the whole of the frescoes in the Chapel of San Diego in the Church of San Giacomo degli Spagnuoli. His best-known frescoes are on mythological subjects, such as the "Dance of the Amorini" (c. 1625; Brera, Milan). In 1616 he returned to Bologna, where he remained except for visits to Mantua in 1621–22 and Florence in 1633.

Albania, officially REPUBLIC OF ALBANIA, Albanian SHQIPËRIA, or REPUBLIKA E SHQIPËRISË, country in the Balkan Peninsula, on its western Adriatic coast. Albania is about 210 miles (340 km) long from north to south and nearly 95 miles (153 km) across at its widest extent from east to west. It is bordered on the north and northeast by Serbia and Montenegro, on the east by Macedonia, and on the southeast by Greece; its western border consists of a rugged coastline along the Adriatic Sea. The capital is Tiranë. Area 11,082 square miles (28,703 square km). Pop. (2003 est.) 3,166,000.

A brief treatment of Albania follows. For full treatment, *see* MACROPAEDIA: Balkan States.

For current history and for statistics on society and economy, *see* BRITANNICA BOOK OF THE YEAR.

The land. Albania may be divided into two major physiographic regions, a mountainous highland region (north, east, and south) constituting 70 percent of the land area and a western coastal lowland region that contains nearly all of the country's agricultural lands and is the most densely populated part of Albania. The highland region can be divided further into the North Albanian Alps, consisting of rugged limestone peaks reaching heights exceeding 8,800 feet (2,700 m); the central uplands, containing several rugged ranges of mountains along the Macedonian border, including Albania's highest peak, Korab (9,025 feet [2,751 m]); and the southern highlands, displaying lower and gentler relief than the northern ranges. Though a coastal country, Albania's mountainous landscape gives it an average elevation of more than 2,300 feet (700 m), about twice the average of Europe. The Drin and other rivers drain westward into the Adriatic. The coastal regions experience a Mediterranean climate, with mild, rainy winters and warm, dry summers. There is an abrupt transition in the mountain regions to a more severe continental climate with hot to warm summers (depending on elevation) and cold winters. Average annual precipitation varies from more than 100 inches (2,500 mm) in the Albanian Alps to less than 30 inches (800 mm) along much of the eastern border.

Albania's natural vegetation is greatly affected by the mountainous topography. The

drier lowlands have a preponderance of maquis (a Mediterranean bush and scrub complex). Sparse oak forest is dominant up to about 3,000 feet (1,000 m), where it is replaced by forests dominated by beech and chestnut, while coniferous forests predominate at higher elevations.

The people. The Albanians are descendants of the ancient Illyrians, who lived in central

Albania

Europe and migrated southward to the Gulf of Árta in northern Greece by the beginning of the Iron Age. The two major modern language communities in Albania are the Gëgs (Ghegs) in the north and the Tosks in the south. There are also a number of ethnic Greeks, concentrated mainly in the southeast. The vast majority of the population is Muslim, and the rest who profess a religion are Orthodox (Albanian) or Roman Catholic.

Albania long had the highest birth rate in Europe; although still high by European standards, it has been dropping since 1990 as has the rate of natural increase. Life expectancy is about 69 years for men and 75 years for women. More than two-fifths of Albanians are urban residents, and the leading city is Tiranë.

The economy. Albania has a developing economy that before 1991 was shaped by the socialist system of complete ownership by the state of the means of production. The government introduced an economic-reform program emphasizing a free-market economy and privatization in 1992. The gross national product (GNP) per capita is one of the lowest in Europe.

About one-fourth of Albania's land is arable, and nearly half of that is allocated to grains. Another one-seventh of the country's total land area is permanent pasture, and about two-fifths is forested. More than half of Albania's cultivated cropland is irrigated. Crops include wheat, corn (maize), barley, oats, tomatoes, sugar beets, cotton, sunflower seeds, tobacco, potatoes, and fruits. Sheep, goats, cattle, and poultry are the major livestock.

Albania's mountainous terrain has rich mineral deposits, and the swiftly flowing rivers have good hydroelectric-energy potential. Energy-related minerals produced include crude petroleum, lignite (brown coal), and natural gas. Metallic minerals include chrome ore, nickeliferous iron ore, and copper ore. Albania's modest reserves of petroleum and natural gas supply a large share of the country's domestic needs, with some surplus for export. More than nine-tenths of the country's electricity is generated from hydroelectric plants.

Albania's manufactures include cement, foodstuffs and beverages, rolled steel, and textiles and clothing. Consumer goods remain in short supply throughout the country.

Prior to 1945 Albania had neither a standard-gauge railway nor a highway network, but by the mid-1980s Tiranë was linked by rail to all other major industrial centres in the country and to Yugoslavia (now Serbia and Montenegro), and the highway network was extended even to remote mountain villages. Albania has four ports on the Adriatic.

Albania's exports include textiles and cloth-

ing, footwear, chrome ore and iron ore, and foods and beverages. Imports consist of foods and beverages, machinery and transport equipment, chemicals and mineral fuels, and metal products. The country's major trading partners include Italy, Greece, Germany.

Government and social conditions. From 1944 to 1990 Albania was a one-party communist state. Members of the Albanian Party of Labour (renamed the Socialist Party in 1991) made all crucial political decisions, which were then endorsed by the People's Assembly. In 1991 noncommunist deputies were elected to the People's Assembly. The following year the noncommunist Democratic Party won a decisive majority in the legislature (which consists of 140 seats). By law, the Assembly elects the president, who in turn appoints the prime minister, who then forms the Council of Ministers (the cabinet).

Albania has a noncontributory social-insurance system, and medical treatment is free, though health conditions remain poor for a European country. All education in Albania is free and is compulsory between ages 6 and 14. Higher education in Albania centres on the University of Tiranë (1957).

History. The Albanians are descended from the Illyrians, an ancient Indo-European people, and have resided throughout the greater part of their history in the western half of the Balkan Peninsula from at least 1000 BC. The southern Albanian tribes were influenced by Greek culture; the modern Albanian cities of Durrës and Lezhë were founded as Greek colonies. The northern Illyrians were united at various times under local kings, the most important of whom was Argon (second half of the 3rd century BC), whose kingdom extended from Dalmatia in the north to the Vjosë River in the south and whose capital was located at Shkodër. After his death, the conquests of his wife, Teuta, aroused the Romans, who by 168 BC conquered all of Illyria. Albania then became part of the Roman province of Illyricum.

Illyricum prospered under the Romans. After 395 the area was connected administratively to Constantinople (now Istanbul). In spite of the Visigoth and Hun invasions during the 3rd to 5th centuries and the Slavic invasions of the 6th and 7th centuries, the Albanians were one of the few peoples in the Balkans who kept their own language and customs.

Turkish invasions began in the 14th century. The Ottoman domination was held back by the national hero, Gjergj Kastrioti, whom the Turks had trained, converted to Islām, and called Skanderbeg. In 1443 he reembraced Christianity and successfully resisted Turkish rule in Albania. After his death, the Turks consolidated their rule over Albania. There was local resistance to Ottoman rule, and an uprising in 1912 created an independent Albania. Italy, under Benito Mussolini, invaded Albania in 1939, and civil war in 1943–44 resulted in the establishment of socialist Albania. Under the rule of Enver Hoxha (1944–85), the economy was nationalized under the supervision of the Albanian Party of Labour, which was the only legal political party. Albania went through a series of economic and military alliances with Yugoslavia, the Soviet Union, and China before it adopted a policy of rigid self-reliance and isolation. The country was thus effectively cut off from most of Europe for several decades, but in 1990 the economic hardships imposed by this isolation forced Hoxha's successor, Ramiz Alia, to reopen Albania to the world. Popular discontent also forced him to loosen state control over the economy and to legalize the political opposition. Multiparty elections held in March 1992 were won by the noncommunist Democratic Party, with the communists (renamed the Socialist Party) retaining only about one-fourth of the parliamentary seats.

In 1997 the economy and government col-

lapsed when many Albanians lost their savings in various pyramid investment schemes. United Nations peacekeeping troops were brought in to quell the resulting civil disorder, and the Socialist Party won by a landslide in legislative elections later that year (maintaining power in elections in 2001 at the head of the Alliance for the State coalition). In 1999 some 450,000 ethnic Albanians sought refuge in Albania from the war in the Kosovo region of Yugoslavia (now Serbia and Montenegro). And ethnic turmoil also strained Albania's relations with Macedonia in 2001 when that country's large Albanian minority staged an armed rebellion.

Albanian language, an Indo-European language spoken in Albania and by smaller numbers of ethnic Albanians in other parts of the southern Balkans, along the east coast of Italy, in southern Greece, and in Ukraine. Albanian is the only modern representative of a distinct branch of the Indo-European language family.

A brief treatment of the Albanian language follows. For full treatment, see MACROPAEDIA: Languages of the World.

The Albanian language has two principal dialects, Geg (Gheg) and Tosk, which are mutually intelligible in their most common forms. The Shkumbin River in Albania constitutes a rough dividing line for the dialects, forms of Geg being common to the north and Tosk to the south. Albanian speakers in Italian and Greek villages employ varieties of Tosk.

The characteristic sound of Albanian resembles that of Hungarian or Greek, with the Geg dialect having the more unusual sound owing to the number of nasal vowels. Grammatically, Albanian retains many archaic traits but bears similarities to modern Greek and the Romance languages. Nouns are declined into three or four cases and show number and gender. An exceptional feature of Albanian grammar is the inflectional attribute of nouns, with changes occurring to specify either definite or general meaning. Nouns, with few exceptions (numerals are one), are followed by their adjectives, and an agreeing particle is required by the adjective; the particle precedes the noun. Verbs are commonly irregular in stem formation. The Albanian vocabulary has been heavily affected by contacts with other languages, particularly Latin; since the 16th century major influences are also apparent from Italian, Turkish, modern Greek, Serbian, and Slav.

The Albanian language is apparently descended from the ancient Illyrian language. The earliest written Albanian records come from the Geg area in makeshift spellings based on Italian or Greek and sometimes in Turko-Arabic characters. The first recorded evidence of the written language is a baptismal formula from 1462. In 1909 an official, standardized Albanian spelling was developed, based on the Geg dialect and employing the Latin alphabet. After World War II the official language changed in that it adopted the Tosk dialect as its model.

Albanian is of special interest in the study of languages because it stands alone: it is not a part of a larger subgroup of modern languages. It holds its linguistic place along with other principal branches (e.g., Germanic) of the Indo-European language family, despite the fact that the language is spoken by a relatively small number of the world's people.

Albanian League, in full LEAGUE FOR THE DEFENSE OF THE RIGHTS OF THE ALBANIAN NATION, also called LEAGUE OF PRIZREN, first Albanian nationalist organization. Formed at Prizren, Serbia, on July 1, 1878, the league, initially supported by the Turks, tried to influence the Congress of Berlin, which was formulating a peace settlement following the Russo-Turkish War of 1877–78 and which threatened to partition Albania (then part of

the Ottoman Empire) and transfer some of its districts to Montenegro, Serbia, and Greece. Unsuccessful in its appeals to the congress, the league used military force to prevent Montenegro from annexing the northern Albanian districts assigned to it (February 1879 and April 1880); the league also forced the area acquired by Greece to be reduced (1881).

The league, however, was compelled to give up the district of Ulcinj (Dulcigno) to Montenegro (November 1880) and then was crushed by a Turkish army (by May 1881) that had been sent into Albania when the sultan's government became annoyed with the league's demands for political autonomy. Despite its defeat, the league engaged in activities between 1878 and 1881 that not only demonstrated the existence of a genuine nationalist movement in Albania but also gave impetus to that movement, which in 1912 brought about the independence of Albania.

Albanian literature, the body of literature in the Albanian language. Writings exist in both Albanian dialects, Geg (Gheg) and Tosk.

The development of Albanian literature was seriously hindered by the Ottoman Empire, which ruled Albania from the 15th to the late 19th century and prohibited publications in the Albanian language for most of that time. The oldest fragment of writing in Albanian is a baptismal formula dating from 1462. The scattering of Albanian religious books produced in the 16th and 17th centuries originated largely in the Geg area and reflects the activities of Roman Catholic missionaries, who secured permission from the Ottoman sultan to publish books. These works were supplemented by a Latin-Albanian dictionary of 1635. The earliest books in the Tosk dialect were inspired by Greek Orthodoxy and were composed by Albanians living in Sicily.

The forerunner of the modern literary renewal was the Italian-Albanian Jeronim de Rada, who spent his life collecting fragments of folk poetry and weaving them into poetic epics, such as that on the Albanian national hero *Skanderbeg* (1873). De Rada also edited the first Albanian journal, *Fjëmuri* ("Flag of Albania"), which was smuggled into Albania during its four-year existence (1883-87).

Literature became a prime focus for intensifying Albanian nationalism from the 1870s. Albanian societies were formed in Constantinople and the Balkan capitals to publish the works of writers and poets and smuggle them into Albania. Thus the three Frashëri brothers—the playwright Sami Bey, the poet Naim, and the political activist Abdyl—formed a committee of liberation at Prizren in 1878 and dedicated themselves to freeing Albania from Turkish domination and to propagating Albanian books. The society was disbanded by the Ottoman authorities, but its leaders continued their literary activities from exile in Egypt and Bucharest. Mid'hat Frashëri, the son of Abdyl, in 1897 began publishing a pocket-sized literary journal that was extensively smuggled into Albania. The literature of the pre-independence period was militantly patriotic and overtly romantic in its presentation of national history and local folklore.

A standard orthography (spelling) in the Latin alphabet was devised by the folk-poet and satirist Gjergj Fishta and adopted for the Albanian language at a congress of Albanian intellectuals in Bitola (now in Macedonia) in 1908-09. The true flowering of Albanian literature occurred in the decades after independence was won in 1912. The novels and poetic dramas of Mihal Grameno, Foqion Postoli, and Mehdi Frashëri centred on the local customs, blood feuds, intrigues, betrayals, and rivalries of Albanian highlanders as they vied with each other and fought the Turks and

Greeks in the struggle for independence. Mid'hat Frashëri wrote the first book of short stories in Albanian, *Hi dhe shpuzë* (1915; "Ashes and Embers"), about blood feuds and the burning of villages. Albanian poetry in the early 20th century is best represented by the romantic folk-balladeer Gjergj Fishta, the classicizing lyric poet Ndre Mjeda, and the versatile poet Alexander Drenova (pseudonym Asdren).

Important contributions to Albanian literature in the period between the World Wars were made in Boston, Mass., by the exiled writers Kristo Floqi and Faik Konitsa, both of whom edited Albanian literary journals, and by the writer-priest Bishop Fan S. Noli, whose fine Albanian translations of plays by foreign authors greatly enriched the language and are still performed. The 1930s were also notable for the short stories of Ernest Koliqi, which centre on his native highland region of Shkodër and are marked by an imaginative use of prose. The Albanian-Romanian Mit-rush Khuteli (pseudonym of Dhimitër Pasko) was another short-story writer of this period, and the prolific but uneven playwright Kristo Floqi dominated Albanian drama. The Romanian-influenced mystic Lasgush Poradeci emerged as a prominent lyric poet in this period.

The post-World War II communist regime imposed strict standards of ideological orthodoxy on writers, and thus had a deadening effect on the country's literature. A notable exception to the prevailing stagnation was Ismail Kadare, whose novel *Gjenerali i ushtërisë së vdekur* (1963; *The General of the Dead Army*) was translated into the major European languages. He remains the only Albanian writer to win an international reputation.

Albano, Francesco (Italian painter): see Albani, Francesco.

Albano, Lake, Italian LAGO ALBANO, crater lake in the Alban Hills (Colli Albani), southeast of Rome. Elliptical in shape, formed by the fusion of two ancient volcanic craters, it lies 961 feet (293 m) above sea level and has an area of 2 square miles (5 square km) and a maximum depth of 558 feet (170 m). It is fed by underground sources and drained by an artificial outlet, reputedly built in 398-397 BC because the oracle at Delphi said that the Etruscan stronghold of Veii could be taken only when the waters of the lake reached the sea. Among the lakeside towns, the best known are the resorts of Albano Laziale and Castel Gandolfo, the papal summer residence.

Albany, southernmost town and seaport of Western Australia. It lies on the northern shore of Princess Royal Harbour, King George Sound. The naturally broad, deep, sheltered harbour was visited and charted by George Vancouver in 1791. In 1826 the first European settlement in the state, a penal colony called Frederickstown (after Prince Frederick, Duke of York and Albany), was established there by the British. Known as Albany by 1832, it became an important whaling base during the 1840s and, until its closure in 1978, was the last surviving shore-based whaling enterprise in the Southern Hemisphere.

Beginning in 1852, it served as a coaling depot for ships sailing the Indian Ocean. Albany declined temporarily when the newly improved harbour at Fremantle opened in 1900; but with the more recent development of its hinterland, it has revived to become the leading port of the south coastal area.

Albany lies along the Great Southern Railway and the South Western and Albany highways to Perth-Fremantle, 240 miles (386 km) northwest. The town serves an area of dairy, beef, lamb, fruit, and potato farming. Its industries include woolen mills, canneries, and brick, tile, and superphosphate plants. Albany has a mild summer climate and serves as a resort. Pop. (1996) 20,493.

Albany, city, seat (1853) of Dougherty county, southwestern Georgia, U.S. It lies along the Flint River at the head of navigation, about 90 miles (145 km) southeast of Columbus. Founded in 1836 by Colonel Nelson Tift, it was named for Albany, New York, and was early established as a leading cotton market. In 1857 a railroad connected it with Macon. Later, six other rail lines converged on the point to make it a transportation hub.

The city served as a Confederate food and cotton supplier during the American Civil War. Cotton growing declined in the Albany area after a serious boll weevil infestation in 1915. Subsequently, a wider variety of crops were raised, with emphasis on paper-shell pecans and Spanish peanuts (groundnuts) and on livestock.

The city's economy is now based largely on services and diversified manufacturing. Albany State University (1903) is located in the city. The Parks at Chchaw are the site of the annual Chchaw National Indian Festival

Cherokee dancers at the Chehaw National Indian Festival, Albany, Ga.

Kevin Fleming/Corbis

(May). A large U.S. Marine Corps supply depot is nearby and is a major employer. The Albany area has become renowned for its quail hunting. Inc. 1841. Pop. (2000) city, 76,939; Albany MSA, 120,822.

Albany, city, capital (1797) of the state of New York, U.S., and seat (1683) of Albany county. It lies along the Hudson River, 143 miles (230 km) north of New York City. The heart of a metropolitan area that includes Troy and Schenectady, it is a port city, the northern terminus of the deepwater Hudson River Channel, and a natural transshipment point between ocean-going vessels and the New York State Canal System routes west to the Great Lakes.

In 1609 Henry Hudson anchored the *Half-Moon* in the shallows near the site while searching for the Northwest Passage. Fort Nassau, built in 1614 on Castle Island (now part of the Port of Albany), became a trading post for the United Netherland Company. A group of Walloon families built Fort Orange near the site in 1624 and began the first permanent settlement, known as Beverwyck. In 1629 the Dutch West India Company granted tracts along both sides of the river (including Beverwyck) to Kiliaen van Rensselaer, an Amsterdam merchant. Renamed Rensselaerswyck, the area attracted a sizable number of colonists, and in 1652 Peter Stuyvesant, colonial governor for the Dutch West India Company, obtained independent status for the village of Beverwyck from the van Rensselaer family. When Fort Orange surrendered to the British (Sept. 24, 1664), the village was renamed to honour James, duke of York and Albany (later James II). It was granted a city charter by the British governor Thomas Dongan on July 22, 1686. Its strategic location and the construction of Fort Frederick made it a leading colonial city. Its population of 2,273 in 1703 increased to 3,498 in 1790 (the year of the first U.S. census) and to 50,763 by

1850. The Dutch heritage is reflected in many street names and in the annual (May) Tulip Festival held in Washington Park.

In 1689 one of the first intercolonial conventions was held at Albany to discuss a system of mutual defense. A more significant historical gathering took place in 1754, when the Albany Congress adopted Benjamin Franklin's "Plan of Union." This meeting paved the way for the Congress of 1765 and the Continental Congress of 1774. Migrating pioneers began to appear in Albany as early as 1783, and the city, a thriving fur-trading centre, became a major outfitting point for wagon trains going west. The opening of the Erie Canal (1825) and the advent of the railroad (1831) increased the flow of traffic through the city, which became the hub of transportation to Michigan Territory (the upper Great Lakes). Politics remains a prevailing aspect of Albany. Its moderate industrial development includes the manufacture of paper, machine tools, felt, and metal products. The city was one of the first in the U.S. to establish a commercial airport (1919), and in 1932 the opening of the Port of Albany to oceangoing shipping made it a maritime centre.

The city has notable examples of Dutch Colonial, Georgian, and French-Gothic Revival architecture, including Ft. Craigo (c. 1700, by tradition the place where "Yankee Doodle" was written by Richard Shuckburgh and now a state historic site), the Schuyler Mansion (1762), Historic Cherry Hill (1787; home of the van Rensselaer family), the State Bank of Albany (1803), the Old Dutch Church (1799), City Hall (1883), the state capitol (1871–99) in "French Chateau" style, St. Peter's Episcopal Church (1859), and the Joseph Henry Memorial (originally Albany Academy, completed 1815). The focal point of the city is the Empire State Plaza, facing Capitol Park and embracing a building complex of government, cultural, and conventional facilities, including the New York State Museum.

Institutions of higher learning include the State University of New York at Albany (1844); the professional schools of Union University, which include Albany Medical College (1839), Law School (1851), College of Pharmacy (1881), and Dudley Observatory; and the Roman Catholic colleges of St. Rose (1920) and Maria (1958); and Albany Business College (1857). Pop. (2000) city, 95,658; Albany-Schenectady-Troy MSA, 875,583.

Consult the INDEX first

Albany, city, seat of Linn county, western Oregon, U.S., in the Willamette Valley, at the juncture of the Willamette and Calapooya rivers, 26 mi (42 km) south of Salem. Established in 1848 by Walter and Thomas Monteith and named for the New York state capital, it became a shipping point for wool, grain, and cascara bark. The Oregon and California (now Southern Pacific) Railroad arrived in 1870. Wood, leather, metal, and food-processing industries were developed. The U.S. Bureau of Mines maintains the Albany Metallurgy Research Center there. The city is host to the daredevilish World Championship Timber Carnival (July 4). Inc. 1864. Pop. (2000) 40,852.

Albany, DUKES OF, titled Scottish nobility of several creations, grouped below chronologically and indicated by the symbol •.

• **Albany, Robert Stewart, 1st duke of** (b. c. 1340—d. September 1420, Stirling Castle, Stirling, Scot.), regent of Scotland who virtually ruled Scotland from 1388 to 1420, throughout the reign of his weak brother Robert III and during part of the reign of James I, who had been imprisoned in London. The third son of Robert II of Scotland, he was made high chamberlain of Scotland in

1382 and won a military reputation in campaigns against England. Chosen guardian of Scotland in 1388, he retained the control of affairs after his brother John became king as Robert III in 1390. In April 1398 he was created duke of Albany (of the first creation). In 1399, however, his nephew David, duke of Rothesay, the heir to the crown, succeeded him as governor. Uncle and nephew soon differed, and in March 1402 the latter died in prison at Falkland. While Albany and the Earl of Douglas were certainly responsible for the imprisonment of Rothesay, the cause of his death is unknown, though contemporary suspicion pointed to the uncle's guilt.

Restored to the office of governor, the Duke was chosen regent of the kingdom after the death of Robert III in 1406, because the new king, James I, was a prisoner in London. Albany continued, with no great success, to prosecute the war with England, which had been renewed a few years before. Albany died at Stirling Castle and was buried in Dunfermline Abbey. His son, Murdac (or Murdoch) Stewart, succeeded him as 2nd duke of Albany and regent but was seized in 1425 on the orders of James I on unrecorded charges and tried and executed. The dukedom of the first creation became extinct.

• **Albany, Alexander Stewart, duke of**, also called (1455–c. 1458) EARL OF MARCH (b. c. 1454—d. 1485, France), second son of James II of Scotland, created duke of Albany in or before 1458. Both he and John, earl of Mar, quarrelled with their brother James III, who imprisoned them in 1479. Mar died, but Albany escaped to carry on a series of intrigues with the English, who supported his pretensions to the Scottish crown. Although he returned to favour and was lieutenant general of the realm during the winter of 1482–83, he was attainted in 1483 and defeated in another rising in 1484. Escaping to France, he died there the following year.

• **Albany, John Stewart, 2nd duke of** (b. c. 1484—d. June 2, 1536), regent of Scotland during the reign of James V and advocate of close ties between France and Scotland. His father, Alexander Stewart (c. 1454–85), the 1st duke of Albany of the second creation, died when he was scarcely more than an infant, and he was raised in France by his mother, Anne de la Tour d'Auvergne.

In 1515, at the request of the Scottish Parliament, he came to Scotland from France. Inaugurated regent in July, he organized resistance to the English influence of Queen Margaret Tudor, whom he took prisoner at Stirling in August. He was declared heir to the throne on Nov. 13, 1516. Returning to France in 1517 he concluded the Treaty of Rouen, which renewed the alliance between France and Scotland and stipulated that a daughter of Francis I of France should marry James V of Scotland.

Returning to Scotland at the close of 1521, he immediately became the object of English attacks. He reconciled himself temporarily with Margaret and was accused by the English government of scheming to marry her himself. This was denied by the Scots, and the English demand for the regent's dismissal was refused. War with England broke out in September 1522, but Albany had little success in the field and retired to France. Returning again in September 1523, he failed once more and finally left Scotland on May 20, 1524. His regency was expressly terminated by the declaration of Parliament later that year.

From 1530 he acted as French ambassador in Rome. In 1533 he conducted Catherine de Médicis, his wife's niece, to France for her marriage to Henry (afterward Henry II of France). Thereafter much of his time was spent in protracted and fruitless negotiations for the marriage of James V. Albany died leaving no legitimate heir.

• **Albany, Henry Stewart, duke of:** see Darnley, Henry Stewart, Lord.

Albany Congress, conference in U.S. colonial history (June 19–July 11, 1754) at Albany, N.Y., which advocated a union of the British colonies in North America for their

"Join, or Die," the first known American cartoon, published by Benjamin Franklin in his *Pennsylvania Gazette*, 1754, to support his plan for colonial union presented at the Albany Congress

The Granger Collection

security and defense against the French, foreshadowing their later unification. The conference was convened by the British Board of Trade to help cement the loyalty of the Iroquois League, wavering between the French and the British in the early phases of the French and Indian War. After receiving presents, provisions, and promises of redress of grievances, 150 representatives of the tribes withdrew without committing themselves to the British cause. In addition, delegates from seven colonies advocated practical measures resulting in closer regulation of Indian affairs and westward migration of pioneers. Except to plant the germ of an important idea, an adopted proposal of Benjamin Franklin to establish a colonial union with broad powers came to naught.

Albany River, river, north central Ontario, Canada, rising in Lake St. Joseph at an elevation of 1,218 ft (371 m) and flowing generally eastward into James Bay. For 250 mi (400 km) of its 610-mi course, the river is navigable, and it served as an important route during the fur-trading days, when boats sailed inland from the Hudson's Bay Company post of Ft. Albany (established 1684) at the mouth. Its largest tributary is the Kenogami River, which is 200 mi long. The flow of the Ogoki River, a former tributary, has been diverted into Lake Nipigon to increase the hydroelectric output at the Nipigon River power sites.

albarello, pottery jar for apothecaries' ointments and dry drugs made in the Near East and in Spain and produced in Italy from the 15th through the 18th century in the form known as maiolica (*q.v.*), or tin-glazed earthenware. Since the jar had to be easy to hold, use, and shelve, its basic form was cylindrical but incurved for grasping and wide-mouthed for access. All albarellos are about 7 inches (18 centimetres) high. A few have close-set handles, but, because they were not designed to hold liquids, they are generally free of spouts, lips, handles, and outcurved forms. A piece of paper or parchment tied around the rim served as a cover for the jar.

Drug jars from Persia, Syria, and Egypt were introduced into Italy sometime before the 15th century, and lustre-decorated pots of Hispano-Moresque origin (influenced by the Moors in Spain) entered the country by way of Sicily. Spanish and Islāmic influence is apparent in the colours used in the decoration of early 15th-century Italian albarellos, which are often blue on white. A conventional oakleaf and floral design frequently occurs, combining

handsomely with heraldic shields or with scrollwork and an inscribed label, usually an abbreviation of the name of the jar's contents. Geometric patterns are also common. Renaissance craftsmen showed their ingenuity

Hispano-Moresque albarello from Valencia, Spain, 15th century; in the Victoria and Albert Museum, London

By courtesy of the Victoria and Albert Museum, London

in the sophisticated polychrome albarellos of the 16th century, in which the early decorative motifs gave way to figurative elements: classical grotesques, portraits, historical scenes, allegories, animals, and other themes. By the end of the 18th century, albarellos had yielded to other containers.

Albatenius: see Battāni, al-

albatross, any of more than a dozen species of large seabirds that collectively make up the family Diomedidae (order Procellariiformes). Because of their tameness on land, many albatrosses are known by the common names mollymawk (from the Dutch for "foolish gull") and gooney. Albatrosses are among the most spectacular gliders of all birds, able to stay aloft in windy weather for hours without ever flapping their extremely long, narrow wings. In calm air an albatross has trouble keeping its stout body airborne and prefers to rest on the water surface. Like other oceanic birds, albatrosses drink seawater. Although they normally live on squid, they also are seen to accompany ships to feed on garbage.

Albatrosses come ashore only to breed. This activity occurs in colonies that are usually

Waved albatross (*Diomedea irrorata*)

Tui De Roy Moore

established on remote oceanic islands, where groups and pairs exhibit mating behaviour that includes wing-stretching and bill-fencing displays accompanied by loud groaning sounds. The single large, white egg, laid on the bare ground or in a heaped-up nest, is incubated by the parents in turn. The growth of the young albatross is very slow, especially in the larger species; it attains flight plumage in 3 to 10 months, then spends the next 5 to 10 years at sea, passing through several pre-adult plumages before coming to land to mate. Albatrosses live long and may be among the few birds to die of old age.

Seamen once held albatrosses in considerable awe; they held that killing an albatross would bring bad luck, a superstition reflected in Samuel Taylor Coleridge's poem "The Rime of the Ancient Mariner." In spite of this superstition, the birds were often taken on baited hooks by sailors for meat. The North Pacific species were slaughtered in large numbers for their feathers, which were used in the millinery trade and as swansdown.

Some of the best-known albatrosses are the following.

The black-browed albatross (*Diomedea melanophris*), with a wingspread to about 230 cm (7.5 feet), wanders far offshore in the North Atlantic; a dark eye-streak gives it a frowning appearance.

The black-footed albatross (*D. nigripes*), one of three North Pacific species, has a wingspread to about 200 cm and is largely sooty brown in colour. It nests on tropical Pacific islands and wanders widely throughout the North Pacific.

Black-browed albatross (*Diomedea melanophris*)

Frans Lanting

The royal albatross (*D. epomophora*), with a wingspread to about 315 cm, is largely white with black outer wing surfaces. It breeds on islands near New Zealand and near the southern tip of South America.

The sooty albatrosses (*Phoebastria*, 2 species), with a wingspread to about 215 cm, have wings and a tail that are longer and more slender than in *Diomedea*. They nest on islands in the southern oceans.

The wandering albatross (*D. exulans*) has a wingspread to more than 340 cm (11 feet), the largest spread among living birds. The adult is essentially like the royal albatross. It nests on islands near the Antarctic Circle and on some islands in the South Atlantic, and in the non-breeding season it roams the southern oceans north to about 30° S.

albedo, fraction of light that is reflected by a body or surface. It is commonly used in astronomy to describe the reflective properties of planets, satellites, and asteroids.

Albedo is usually differentiated into two general types: normal albedo and bond albedo. The former, also called normal reflectance, is a measure of a surface's relative brightness when illuminated and observed vertically. The normal albedo of snow, for example, is nearly 1.0, whereas that of charcoal is about 0.04. Investigators frequently rely on observations of normal albedo to determine the surface compositions of satellites and asteroids. The albedo, diameter, and distance of such objects together determine their brightness. If the asteroids Ceres and Vesta, for example, could be observed at the same distance, Vesta would be the brighter of the two by roughly 10 percent. Though Vesta's diameter measures less than half that of Ceres, Vesta appears brighter because its albedo is about 0.35, whereas that of Ceres is only 0.09.

Bond albedo, defined as the fraction of the total incident solar radiation reflected by a planet back to space, is a measure of the planet's energy balance. (It is so named for the American astronomer George P. Bond, who in 1861 published a comparison of the brightness of the Sun, the Moon, and Jupiter.) The value of bond albedo is dependent on the spectrum of the incident radiation because such albedo is defined over the entire range of wavelengths. Earth-orbiting satellites have been used to measure the Earth's bond albedo. The most recent values obtained are approximately 0.33. The Moon, which has a very tenuous atmosphere and no clouds, has an albedo of 0.12. By contrast, that of Venus, which is covered by dense clouds, is 0.76.

Albee, Edward, in full EDWARD FRANKLIN ALBEE (b. March 12, 1928, Virginia, U.S.), American dramatist and theatrical producer best known for his play *Who's Afraid of Virginia Woolf?* (1962), which displays slashing insight and witty dialogue in its gruesome portrayal of married life.

The adopted child of a family involved in vaudeville theatre, Albee grew up in New York City and nearby Westchester county. He was educated at Choate School (graduated 1946) and Trinity College, Hartford, Conn. (1946–47). He wrote poetry and an unpublished novel but turned to plays in the late 1950s.

Among Albee's early one-act plays, *The Zoo Story* (1959), *The Sandbox* (1960), and *The American Dream* (1961) were the most successful and established him as an astute critic of American values. But it is his first full-length play, *Who's Afraid of Virginia Woolf?* (filmed 1966), that remains his most important work. In this play a middle-aged professor, his wife, and a younger couple engage one night in an unrestrained drinking bout that is filled with malicious games, insults, humiliations, betrayals, savage witticisms, and painful, self-revealing confrontations. *Virginia Woolf* won immediate acclaim and established Albee as a major American playwright. It was followed by a number of full-length works—including *Tiny Alice* (1964), *A Delicate Balance* (1966; winner of a Pulitzer Prize), *Seascape* (1975; Pulitzer Prize), and *Three Tall Women* (1991; Pulitzer Prize)—as well as adaptations of other writers' works. In addition to writing, Albee produced a number of plays and lectured at schools throughout the country.

BIBLIOGRAPHY. Richard E. Amacher, *Edward Albee*, rev. ed. (1982); Philip C. Kolin and J. Madison Davis (eds.), *Critical Essays on Edward Albee* (1986); Matthew C. Roudané, *Understanding Edward Albee* (1987).

Albee, Edward Franklin (b. Oct. 8, 1857, Machias, Maine, U.S.—d. March 11, 1930, Palm Beach, Fla.), theatrical manager who, as the general manager of the Keith-Albee theatre circuit, was the most influential person in vaudeville in the United States. A circus ticket seller when he joined Benjamin Franklin Keith in 1885 to establish the Boston Bijou Theatre, he was responsible for

the expansion of the Keith-Albee vaudeville circuit. By the 1920s it controlled nearly 400 theatres in the East and Midwest. Albee was president of the United Bookings Office from its formation in 1900. In 1916 he organized a union, the National Vaudeville Artists, thus gaining a near monopoly on both talent and production in U.S. vaudeville. Albee dominated vaudeville until 1928, when RKO, a film company, absorbed his circuit in order to acquire the theatres. His adopted grandson, and namesake, was an American playwright.

Albemarle, George Monck, 1st Duke of, Monck also spelled MONK: see Monck, George.

Albemarle Sound, coastal inlet of north-eastern North Carolina, U.S. It is protected from the Atlantic by the Outer Banks, extends (east-west) for about 50 miles (80 km), and varies in width from 5 to 14 miles (8 to 23 km). Its average depth is 5–10 feet (1–3 m), and nowhere is it deeper than 25 feet. It receives the Pasquotank, Alligator, Chowan, and Roanoke rivers and discharges this flow at its southeastern end through the Roanoke and Croatan sounds to Pamlico Sound. It is connected with Chesapeake Bay by the Dismal Swamp and the Albemarle and Chesapeake Canal and is crossed by the Atlantic Intercoastal Waterway. Elizabeth City is the chief port. Explored by Ralph Lane from the Roanoke Island colony in 1585, it was first called the Sea of Rawnocke (Roanoke Sea) and later Albemarle Bay or River after George Monck, Duke of Albemarle. Along its shores were the state's earliest European settlements.

Albéniz, Isaac (Manuel Francisco) (b. May 29, 1860, Camprodón, Spain—d. May 18, 1909, Cambo-les-Bains, France), composer and virtuoso pianist, a leader of the Spanish nationalist school of musicians.

Albéniz appeared as a piano prodigy at age 4 and by 12 had run away from home twice. Both times he supported himself by concert tours, eventually gaining his father's consent to his wanderings. He studied at the Leipzig Conservatory in 1875–76 and, when his money ran out, obtained a scholarship to study in Brussels. From 1883 he taught in Barcelona and Madrid. He had previously composed facile salon music for piano, but about 1890 he began to take composition seriously. He studied with Felipe Pedrell, father of the nationalist movement in Spanish music, and in 1893 moved to Paris. There he came under the influence of Vincent d'Indy, Paul Dukas, and other French composers and for a time taught piano at the Schola Cantorum. He later developed Bright's disease and was a near invalid for several years before he died.

Albéniz' fame rests chiefly on his piano pieces, which utilize the melodic styles, rhythms, and harmonies of Spanish folk music. The most notable work is *Iberia* (1905–09), a collection of 12 virtuoso piano pieces, considered by many to be a profound evocation of the spirit of Spain, particularly of Andalusia. Also among his best works are the

Suite española, containing the popular "Sevillana"; the *Cantos de España*, which includes "Córdoba"; *Navarra*; and the *Tango in D Major*. Orchestrated versions of many of his pieces are also frequently played.

Alberdi, Juan Bautista (b. Aug. 20, 1810, San Miguel de Tucumán, Río de la Plata [now in Argentina]—d. June 18, 1884, Paris,

Alberdi, portrait by an unknown artist

By courtesy of the Archivo General de la Nación Buenos Aires

France), Argentine political thinker whose writings influenced the assembly that drew up the constitution of 1853.

As an opponent of the dictator Juan Manuel de Rosas, Alberdi went into exile in 1838, studying law in Uruguay and also living in Chile and in Europe. After the overthrow of Rosas in 1852, Alberdi wrote his major book, *Bases y puntos de partida para la organización política de la República Argentina* ("Bases and Starting Points for the Political Organization of the Argentine Republic"), which emphasized the need for a federal government and argued for attracting foreign capital and immigrants; his approach was encapsulated by his dictum "Gobernar es poblar" ("To govern is to populate").

In the 1850s Alberdi was Argentine plenipotentiary in Paris, Madrid, Washington, and London. He lost official favour in the 1860s, partly because of his opposition to the Paraguayan War (1864–70). He spent his last years in semi-exile in Europe.

Alberoni, Giulio (b. May 21, 1664, Piacenza, duchy of Parma [Italy]—d. June 16, 1752, Piacenza), statesman who as de facto premier

Alberoni, detail of an engraving by Weber

By courtesy of the Bibliothèque Nationale, Paris

of Spain (1716–19) played a major role in the revival of that nation after the War of the Spanish Succession (1701–14).

The son of a gardener, Alberoni was educated by the Jesuits, took holy orders, and in 1698 was appointed a canon at Parma, in Italy. In 1702 the government of Parma sent him on a diplomatic mission to Louis-Joseph, Duke de Vendôme, commander of French forces in Italy during the War of the Spanish Succession. Taken by Vendôme to France as secretary in 1706 and to Spain (1711), he nevertheless continued as an agent of Parma.

After Vendôme's death (1712), Alberoni remained in Madrid, becoming the official representative of Parma the following year. He negotiated the marriage of Philip V of Spain to Elizabeth (Isabella) Farnese, daughter of the Duke of Parma. His influence at the Spanish court increased steadily, and by 1716 he was exercising the powers of a premier.

Alberoni continued the administrative centralization and fiscal reform begun by the French economist Jean Orry, who exercised considerable influence in the government of Spain during the first years of Bourbon rule there. He also encouraged the establishment of industry through tariff reform and the importation of foreign craftsmen. His outstanding achievement, however, was the diminution of the royal councils—centres of aristocratic opposition to reform—which he accomplished through a series of decrees in 1717. His foreign policy was designed to drive the Austrians from Italy and to safeguard Spanish trade with its American colonies. The Spanish military expeditions to Sardinia (1717) and Sicily (1718) that led to war with the Quadruple Alliance (Great Britain, France, Austria, and the United Provinces), which he regarded as premature, resulted from a policy imposed on him by the queen. The defeat of Spanish forces during the Franco-British invasion of Spain resulted in his banishment in 1719.

Alberoni fled from Spain to Italy, where (having been made a cardinal in 1717) he took part in the conclave that elected Pope Innocent XIII in 1721; he was later acquitted by a papal inquiry into charges brought against him by Spain. He became legate of Ravenna in 1735 and of Bologna in 1740.

Albers, Josef (b. March 19, 1888, Bottrop, Ger.—d. March 25, 1976, New Haven, Conn., U.S.), painter, poet, teacher, and theoretician of art, important as an innovator of such styles as Colour Field painting and Op art.

From 1908 to 1920 Albers studied in Berlin, Essen, and Munich and taught elementary school in his native town. In 1920 he enrolled at the newly formed Bauhaus, soon to become the most important school of design in Germany. His most important creations of that period were compositions made of coloured glass. After 1923, when he became a teacher at the Bauhaus, Albers created a style of painting characterized by the reiteration of abstract rectilinear patterns and the use of primary colours along with white and black.

In 1933, when the Nazi government closed the Bauhaus, Albers left Germany for the U.S. He organized the fine-arts curriculum at

Black Mountain College, in North Carolina, where he taught until 1949. The next year he began a 10-year tenure as chairman of the art department of Yale University.

After moving to the United States, Albers concentrated on several series of works that systematically explored the ambiguous relationships between the physical object of art and its psychological effect. In his series of engraved plastic "Transformations of a Scheme" (1948–52) and in the series of drawings "Structural Constellations" (1953–58) he created complex linear designs, each subject to many possible spatial interpretations. His best-known series of paintings, "Homage to the Square," restricts its repertory of forms to superimposed squares of colour carefully calculated so that the colour of each square appears to alter the sizes, hues, and spatial relationships of the other squares.

AUSTRIA

● **Albert I**: see Albert I (Germany/Holy Roman Empire).

● **Albert V**: see Albert II (Germany/Holy Roman Empire).

● **Albert VII** (b. Nov. 11, 1559, Wiener Neustadt, Austria—d. July 13, 1621, Brussels, Spanish Netherlands [now in Belgium]), cardinal archduke of Austria who as governor and sovereign prince of the Low Countries (1598–1621) ruled the Spanish Netherlands jointly with his wife, Isabella, infanta of Spain (see Isabella Clara Eugenia).

The son of the Holy Roman emperor Maximilian II, Albert was educated for an ecclesiastical career at the court of his uncle, King Philip II of Spain. Although appointed archbishop and cardinal of Toledo (Spain) in 1577, Albert served Philip not as a prelate but as a soldier and diplomat; he governed Portugal as Philip's viceroy from 1581 (or 1585) to 1595. After the death of his elder brother, Ernest, governor of the Netherlands, in February 1595, he was appointed governor-general by Philip and given the task of subduing the rebellious Protestants in the seven United Provinces of the north. At Philip's insistence, Albert reluctantly obtained a papal release from holy orders and dispensation to marry Philip's daughter, the infanta Isabella. He received joint sovereignty of the Low Countries in 1598 as dowry for his marriage (April 1599) to Isabella. Because Albert could effect neither a military defeat of the United Provinces nor a political reconciliation, he and Isabella controlled only the 10 Roman Catholic provinces of the south. After several years of inconclusive fighting, an armistice was arranged with the Dutch in April 1607, and a 12-year truce began in 1609. During the truce period Albert strengthened the Catholic religion in the Spanish Netherlands and did much to promote the arts.

BELGIUM

● **Albert I** (b. April 8, 1875, Brussels, Belg.—d. Feb. 17, 1934, Marche-les-Dames, near Namur), king of the Belgians (1909–34), who led the Belgian army during World War I and guided his country's postwar recovery.

The younger son of Philip, count of Flanders

(brother of King Leopold II), Albert succeeded to the throne in 1909—Leopold's son and Albert's father and older brother having died earlier. Before World War I, Albert worked to

Albert I
EB Inc

strengthen the army, gaining passage in 1913 of a military conscription bill. He reaffirmed Belgian neutrality to France and Germany in the summer of 1914 and rejected the German emperor William II's ultimatum of Aug. 2, 1914, demanding free passage of German troops across Belgian territory. A German invasion followed two days later.

Albert assumed leadership of the Belgian army at the outset of the war but was forced to retreat beyond the Yser River after the fall of Antwerp in October 1914. German troops then occupied the entire country except for the southwestern districts of Flanders. During the whole of the war Albert remained with his troops, making continual visits to the front-line trenches from his headquarters at De Panne on the Belgian coast. When the general Allied offensive of September 1918 was undertaken, he commanded the Franco-Belgian northern army group, which captured Ostend and Brugge and forced the passage of the Lys River.

Following the Armistice Albert appealed to the Allies to abolish Belgian neutrality, formalized by European treaties in 1839, and gained passage in Parliament of universal male suffrage. For the next 15 years he guided the nation's rebuilding effort, which included public-works construction and redevelopment of industries destroyed by the German occupation. In 1926 he helped introduce a new monetary system. Albert was killed by a fall while rock-climbing in 1934.

● **Albert II**, in full ALBERT FÉLIX HUBERT THÉODORE CHRISTIAN EUGÈNE MARIE OF SAXE-COBURG-GOTHA (b. June 6, 1934, Brussels, Belg.), king of Belgium from 1993.

The second son of King Leopold III, Albert was educated at home and in Geneva and Brussels and entered the Belgian navy in 1953. From 1962 until his ascension, he served as honorary chairman of the Belgian Office of Foreign Trade, becoming an expert on shipping. He was also president of the Belgian Red Cross. In 1959 he married Paola Ruffo di Calabria, an Italian princess. The couple had three children: Philippe (b. 1960), Astrid (b. 1962), and a second son, Laurent (b. 1963). Albert succeeded his childless older brother Baudouin after the latter's death in July 1993. Albert was sworn in as sixth king of the Belgians on Aug. 9, 1993.

BOHEMIA

● **Albert**: see Albert II (Germany/Holy Roman Empire).

BRANDENBURG

● **Albert I**, also called ALBERT THE BEAR, German ALBRECHT DER BÄR (b. c. 1100—d. Nov. 18, 1170), the first margrave of Brandenburg and founder of the Ascanian dynasties (*q.v.*). He was one of the main leaders of

12th-century German expansion into eastern Europe.

In 1123 Albert inherited Saxon estates between the Harz Mountains and the middle reaches of the Elbe River from his father, Otto the Rich. After his mother's death in 1142, he received the central German possessions of the Billung dynasty, but he was unsuccessful in his attempts to win the Saxon duchy.

His greatest achievement was in the east, where, in return for his services to the Holy Roman emperor Lothair II, in Italy (1132), he received the North Mark, east of the junction of the Elbe and Havel rivers (1134). He spent three years campaigning against the Wends and, by an arrangement made with Pribislav, prince of the Havelland, he obtained that district after the prince's death in 1150. Taking the title margrave of Brandenburg, Albert pressed the warfare against the Wends, extended the area of his mark, and increased its population and prosperity by introducing Frisian and Saxon settlers. Albert had the help of the Premonstratensians and Cistercians in forest clearance and drainage of swamps. He coupled colonization with missionary work among the Slavs and revived the bishoprics of Havelberg and Brandenburg.

Lothair's successor, Frederick I Barbarossa, may have made Albert archchamberlain of the empire, an office that later gave the margraves of Brandenburg the rights of an elector.

● **Albert III Achilles** (b. Nov. 24, 1414, Tangermünde, Brandenburg [now in Germany]—d. March 11, 1486, Frankfurt am Main), elector of Brandenburg, soldier, and administrative innovator who established the principle by which the mark of Brandenburg was to pass intact to the eldest son.

The third son of Frederick of Hohenzollern, elector of Brandenburg, Albert received his family's Ansbach lands upon Frederick's death in 1440. He added Bayreuth at his brother John's death (1464), and when his brother Frederick II abdicated in 1470 he became elector of the mark of Brandenburg.

Throughout much of his life, Albert was engaged in warfare, harbouring a strong antipathy toward the relative autonomy of cities and towns, especially Nürnberg, which he tried to subdue several times. His administrative policy was more effective than his campaigns, however. On Feb. 24, 1473, he proclaimed the *Dispositio Achillea* ("Disposition of Achilles"), which was to preserve Brandenburg as a united whole and keep his dynastic inheritance intact. This settlement gave the mark of Brandenburg to his eldest son and the Hohenzollerns' then more lucrative Franconian possessions to younger sons. While not establishing primogeniture as such, he made a significant step in that direction.

Albert effectively administered his lands, combating aristocratic banditry, paying his officials salaries, tightening controls over them, and instituting an accounting system in his territories. In the German political sphere, he sided with the Habsburgs for most of his life. At the Frankfurt Reichstag (1486) he supported Maximilian I's election as German king. He also worked for currency and judicial reform and *Landesfrieden* ("peace throughout the land") for all of Germany.

BRANDENBURG-KULMBACH

● **Albert II Alcibiades** (b. March 28, 1522, Ansbach [Germany]—d. Jan. 8, 1557, Baden), margrave of Brandenburg-Kulmbach, member of the Franconian branch of the Hohenzollern family, and a soldier of fortune in the wars between the Habsburgs and the Valois dynasty of France.

Albert served the Holy Roman emperor Charles V until January 1552, when he joined his friend Maurice, elector of Saxony, in a league with Charles's enemy, Henry II of

France. The allied forces drove Charles out of Innsbruck, and the Emperor's brother Ferdinand negotiated the Treaty of Passau (August 1552) with Maurice, thereby achieving a truce in the religious disputes within Germany. Albert, however, rejected the treaty and again offered his services to Charles, who was attempting to retake Metz from the French. In return, Charles ratified Albert's seizure of large German territories. By early 1553, however, Charles had handed over control of German affairs to Ferdinand. Maurice, who had allied himself with Ferdinand, then led a coalition against Albert, who was defeated at Sievershausen (July 9, 1553). Not long after (December 1), the Imperial Chamber at Speyer outlawed Albert, and he sought asylum in France (June 1554). In 1556 Albert returned to Germany with plans of revenge but died before he could carry them out.

GERMANY/HOLY ROMAN EMPIRE

• **Albert I** (b. c. 1255—d. May 1, 1308, Brugg, Switz.), duke of Austria and German king from 1298 to 1308, who repressed private war, befriended the serfs, and protected the persecuted Jews.

The eldest son of King Rudolf I of the House of Habsburg, Albert was invested with the duchies of Austria and Styria in 1282. After Rudolf's death (1291), the electors, determined to prevent the German crown from becoming a hereditary possession of the Habsburgs, chose Adolf of Nassau as German king. Albert, however, drew the electors into an alliance and engineered the deposition (June 23, 1298) of Adolf, who was defeated in battle and slain on July 2, 1298, at Gölheim.

Albert I, engraving by an unknown artist
By courtesy of the Bild-Archiv, Österreichische Nationalbibliothek Vienna

Albert's election, proclaimed at Mainz before the battle, was repeated at Frankfurt on July 27; he was crowned at Aachen on August 24.

Albert formed an alliance in 1299 with Philip IV of France against Pope Boniface VIII, who had refused to recognize him as king. He tried to increase the power of his house by claiming (unsuccessfully) possession of Holland, Zealand, and Frisia as vacant fiefs. His pro-French policy and his effort to control the mouths of the Rhine were opposed by the four Rhenish electors, who tried to depose him. Albert, aided by the cities of the Rhineland, crushed the coalition in a series of campaigns between 1300 and 1302. He obtained confirmation of his election from Pope Boniface VIII on April 30, 1303, swore an oath of obedience to the pope, and promised that none of his sons should be elected German king without papal consent. His attempt to place his son Rudolf on the vacant throne of Bohemia in

1306 was only momentarily successful, and his claim to Thuringia and Meissen, inherited from Adolf of Nassau, was checked by a defeat near Lucka in 1307. Albert was assassinated by his nephew John of Swabia, later called the "Parricide," from whom the king had unjustly withheld his inheritance.

• **Albert II** (b. Aug. 16, 1397—d. Oct. 27, 1439, Neszmély, Hung.), German king from 1438, king (Albert) of Hungary, king (Albrecht) of Bohemia, and duke (Albrecht) of

Albert II, engraving by Philipp Kilian
By courtesy of the Bild-Archiv, Österreichische Nationalbibliothek, Vienna

Luxembourg. As a member of the Habsburg dynasty he was archduke (Albert V) of Austria from infancy (1404).

On the death of his father-in-law, the Holy Roman emperor Sigismund, Albert was crowned king of Hungary (Jan. 1, 1438), elected king of Germany (March 18), and, despite opposition, actually crowned king of Bohemia (June 29). Calling a diet at Nürnberg (1438), he ended all feuds based on the right of private warfare and appointed arbiters to settle disputes. He further divided Germany into administrative circles, again with the maintenance of peace in mind. Although he died the following year during a campaign against the Turks, the rule of Albert's successors was stabilized through his measures.

MAINZ

• **Albert**, also called ALBERT OF BRANDENBURG, German ALBRECHT VON BRANDEN-

Albert of Brandenburg, engraving by Albrecht Dürer, 1523

Archiv für Kunst und Geschichte, Berlin

BURG (b. June 28, 1490—d. Sept. 24, 1545, Mainz, Ger.), margrave of Brandenburg, cardinal, and elector and archbishop of Mainz and Magdeburg, a liberal patron of the arts known chiefly as the object of the reformer Martin Luther's attacks concerning the sale of indulgences.

In order to gain the agreement of Pope Leo X to his holding more than one diocese, which was contrary to church law, Albert made a large contribution toward the rebuilding of St. Peter's Basilica in Rome. These funds, borrowed from the banking house of Fugger, were to be repaid through the sale of indulgences, half the proceeds going to Albert, the other half to Leo X. Luther condemned this practice in his Ninety-five Theses.

In 1518 Albert was created cardinal. A religious liberal, he was a friend of the Humanists Ulrich von Hutten and Desiderius Erasmus. Late in life Albert became less tolerant of Protestantism and helped foster the German Counter-Reformation.

MONACO

• **Albert I**, in full ALBERT-HONORÉ-CHARLES GRIMALDI (b. Nov. 13, 1848, Paris—d. June 26, 1922, Paris), prince of Monaco (1889–1922), seaman, amateur oceanographer, and patron of the sciences, whose contributions to the development of oceanography included innovations in oceanographic equipment and technique and the founding and endowment of institutions to further basic research.

As a young man Albert served in the Spanish Navy. Later, he conducted his own oceanographic surveys on a series of increasingly large and well-equipped ships. His active involvement in oceanography continued even after he became ruler of Monaco—upon the death of his father, Charles III (1889)—and culminated in his establishment of the Oceanographic Museum of Monaco (1899) and the Oceanographic Institute in Paris (1906).

Albert was succeeded as prince of Monaco by his son, Louis II (1870–1949).

• **Albert II**, in full ALBERT ALEXANDRE LOUIS PIERRE DE GRIMALDI (b. March 14, 1958, Monaco), prince of Monaco (2005–). He was the only son of Rainier III, prince de Monaco, and Grace Kelly, a former actress.

Albert attended Amherst College (B.A., 1981) in Massachusetts. Following his mother's death in 1982, he became president of the Monaco Red Cross. An avid sportsman, he was a five-time Olympian, competing on the principality's bobsled team. In 1994 he became chair of Monaco's Olympic committee.

As his father's health declined in the early 21st century, Albert assumed greater royal responsibilities. In April 2005 Prince Rainier died, and Albert formally assumed the throne on July 12. He did so amid controversy as days earlier he had publicly acknowledged that he had fathered a son out of wedlock. The child, however, was barred from inheriting the throne due to a 2002 constitutional amendment that required the heir's parents to be married.

NETHERLANDS

• **Albert:** *see* Albert VII (Austria).

PAPACY

• **Albert**, also called ALERIC (fl. early 12th century), antipope in 1102. He was cardinal bishop of Sabina when elected in February or March 1102 as successor to the antipope Theodoric of Santa Rufina, who had been set up against the legitimate pope, Paschal II, by an imperial faction supporting the Holy Roman emperor Henry IV in his struggle with Paschal for supremacy. Albert's uncanoni-

cal investiture was not accepted and he was soon imprisoned. Later, Paschal ordered him blinded and sent to a monastery, where he remained a monk the rest of his life.

PRUSSIA

• **Albert** (b. May 17, 1490, Ansbach—d. March 20, 1568, Tapiau, East Prussia), last grand master of the Teutonic Knights from 1510 to 1525, first duke of Prussia (from 1525), a Protestant German ruler known chiefly for ending the Teutonic Knights' government of

Albert of Prussia, miniature by Heinrich Königswieser, 1564; in the Kaiser-Friedrichs-Museum, Berlin
By courtesy of the Staatsbibliothek Berlin

East Prussia and founding a hereditary dukedom in its place.

Albert was the third son of Frederick of Hohenzollern, margrave of Ansbach-Bayreuth. In 1510 Albert was named grand master of the Teutonic Order and thus lord of East Prussia, which the order held under Polish suzerainty. A quarrel with the Poles, however, resulted in a war with Poland (1519–21) that caused considerable damage to East Prussia. During the truce that followed, the dispute remained unsettled.

In 1523 the religious reformer Martin Luther advised Albert to dissolve the Teutonic Order and transform his Prussian holdings into a hereditary dukedom under the Polish crown, a solution accepted by King Sigismund I of Poland in 1525. The Holy Roman emperor Charles V in the 1530s placed Albert, now a Protestant, under the ban of the empire and demanded the return of East Prussia to the Teutonic Knights, but the faithful remnant of the latter, with scattered bases in Germany, could do nothing against Albert.

Albert joined anti-imperial coalitions and cultivated Protestant Denmark and Sweden. At home, the East Prussian administration was secularized, but considerable privileges had to be conceded to the nobility before they would confirm his rule and grant him funds to govern.

In his later years, Albert fell under the influence of theological and political adventurers, and his reign became marred by violent disputes. The University of Königsberg, founded on his initiative in 1544, was long troubled by such difficulties. Quiet had once again been restored, orthodox Lutheranism declared binding, the succession finally settled, and the adventurers either expelled or executed, when Albert died.

SAXONY

• **Albert III**, also called **ALBERT ANIMOSUS**, OF THE COURAGEOUS, German **ALBRECHT DER BEHERZTE** (b. July 27/31, 1443, Grimma, Saxony—d. Sept. 12, 1500, Emden, East Fri-

sia), duke of Saxony, founder of the Albertine branch of the House of Wettin, and marshal of the Holy Roman Empire.

Albert was the son of Frederick II, elector of Saxony. When he was 12 years of age, he and his brother Ernest were abducted by their father's enemy, the Saxon noble Kunz von Kaufungen, who was quickly thwarted and executed. The incident is known as the *Prinzenraub*, and it became a popular subject for legend and literature, particularly for 16th-century German dramatists. On the death of their father, the brothers ruled their Saxon territories jointly until the Leipzig partition of 1485, when the lands were split between them.

In 1471 Albert's candidature for the Bohemian throne had failed. Governor of the Netherlands for the Holy Roman emperors from 1488 to 1493, he was rewarded for this service in 1498 with the hereditary governorship of Friesland.

• **Albert** (b. April 23, 1828, Dresden, Saxony—d. June 19, 1902, near Ols, Silesia), king of Saxony from Oct. 29, 1873, Catholic king of a Protestant country who was nonetheless popular with his subjects. He also was a capable soldier who fought well in the Seven Weeks' War of 1866 and in the Franco-German War of 1870–71.

He was the eldest son of Prince John, who succeeded to the Saxon throne in 1854. An artillery officer at the age of 15, Albert had one year of university studies at Bonn before serving in the German Schleswig-Holstein campaign of 1849 against the Danes. He married Caroline, granddaughter of King Gustav IV Adolf of Sweden, in 1853. In 1857 he was made general of infantry, and in 1862 he became a member of the upper house of the Saxon parliament.

Commanding the Saxon Army in the Seven Weeks' War, Albert effected an orderly retreat when the Prussians invaded Saxony. After the defeat of Austria and its allies, including Saxony, at Königgrätz (Sadowa) on July 3, 1866, Albert held his position tenaciously. Personally favourable to Prussia, Albert became commander of the XII Corps, formerly the Saxon Army, when his country entered the Prussian-dominated North German Confederation.

In the Franco-German War, Albert's corps played a major part in winning the battles of Gravelotte (August 18) and Sedan (Aug. 31–Sept. 2, 1870). From March 18 to June 8, 1871, he commanded the German army of occupation in France. Soon afterward he was made inspector general of the imperial German Army and was promoted to the rank of field marshal.

As king of Saxony, in succession to his father, Albert was mainly interested in military affairs but approved reforms in local administration, education, and taxation and encouraged industrialization. He left no children and was succeeded by his brother George.

Albert (composer): see Halévy, (Jacques-François-)Fromental(-Élie).

Albert, ARCHDUKE, German in full **ERZHERZOG ALBRECHT, HERZOG (duke) VON TESCHEN** (b. Aug. 3, 1817, Vienna—d. Feb. 18, 1895, Arco, South Tirol, Austria-Hungary), able field marshal who distinguished himself in the suppression of the Italian Revolution of 1848 and in the Austro-Prussian War (1866) and whose reforms turned the Austrian Army into a modern fighting force after its rout by Prussia.

The son of the archduke Charles, who defeated Napoleon at Aspern-Essling, Albert entered the Austrian Army in 1837. He received a thorough military education from Field Marshal Joseph Radetzky and fought under his mentor in the campaign of 1848–49 in Italy, distinguishing himself as a divisional commander at Novara. In 1851 he became

Archduke Albert, detail from a lithograph by Adolph Dauthage, 1856

By courtesy of Bild-Archiv Österreichische Nationalbibliothek Vienna

governor of Hungary, retaining the post until 1863. At the outbreak of the war against Prussia, he commanded the Italian front and won the decisive victory at Custoza (June 1866), which so disorganized the Italians that he was able to detach sizable units for the protection of Vienna, which the Prussians threatened after the Austrian defeat at Königgrätz (Sadowa). He was named commander in chief of all Austrian forces on July 10, 1866, but peace intervened before he had a chance to test his plans.

With the end of hostilities, Albert dedicated himself to the reform of the army, becoming inspector general in 1869. Drawing on the lessons learned from Prussia, he concentrated on the development of industries and railways, the creation of short-service conscription to increase the size of the armed forces, and the introduction and improvement of new weapons and the general-staff system. His efforts created as modern a fighting force as the conservative Austro-Hungarian monarchy, with its diverse nationalities and languages, was able to maintain in the latter half of the 19th century.

Albert, PRINCE CONSORT OF GREAT BRITAIN AND IRELAND, original name **FRANCIS ALBERT AUGUSTUS CHARLES EMMANUEL**, PRINCE OF SAXE-COBURG-GOTHA, German **FRANZ ALBRECHT AUGUST KARL EMMANUEL**, PRINZ VON SACHSEN-COBURG-GOTHA (b. Aug. 26, 1819, Schloss Rosenau, near Coburg, Saxe-Coburg-Gotha—d. Dec. 14, 1861, Windsor, Berkshire, Eng.), the prince consort of Queen Victoria of Great Britain and father of King Edward VII. Although Albert himself was undeservedly unpopular, the domestic happiness of the royal couple was well known and helped to assure the continuation of the monarchy, which was by no means certain on the Queen's accession. On his death from typhoid fever, the British public, which had regarded him almost as an enemy alien, finally recognized his exceptional qualities. Throughout almost 40 years of widowhood, the Queen decided important questions on the

Prince Albert the prince consort, detail of a painting by F.X. Winterhalter, 1867; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

basis of what she thought Albert would have done.

A member of the Ernestine branch of the Wettin dynasty, he was the second son of Ernest, duke of Saxe-Coburg-Gotha. He was educated in Brussels and at the University of Bonn. The marriage between Victoria and Albert, who were first cousins, was promoted by their uncle Leopold I, king of Belgium. On Oct. 15, 1839, the young queen proposed to Albert, and they were married on Feb. 10, 1840.

Albert soon became, in effect, Victoria's private secretary and chief confidential adviser. Following his example, the Queen, who had been inclined to indolence, became almost as hardworking as he. At his urging she abandoned her Whig partisanship in favour of a more seemly political neutrality. Disputes with Prussia in 1856 and the United States in 1861 ended peacefully, at least in part because Albert suggested rewording Foreign Office dispatches so that they could not be construed as ultimatums.

Albert's vigilance was unwelcome to various government ministers, especially Lord Palmerston. The British aristocracy did not care for the severe moral tone of the royal household, for Albert's professorial manner (although he rode and shot as well as they), or for his artistic versatility. In collaboration with the London contractor Thomas Cubitt, Albert designed Osborne House (1845-51), the royal residence on the Isle of Wight. He was also an accomplished musician. He successfully managed the Great Exhibition of 1851 at the Crystal Palace, London, and was planning the South Kensington Exhibition of 1862 when he became fatally ill.

Lieut. Gen. Charles Grey's *Early Years of His Royal Highness the Prince Consort* (1867) and Sir Theodore Martin's *Life of His Royal Highness the Prince Consort*, 5 vol. (1875-80), were prepared at the Queen's insistence. Excellent, and more recent, biographies include Daphne Bennett's *King Without a Crown* (1978) and Robert Rhodes James's *Albert Prince Consort* (1983).

Albert ANIMOSUS: see Albert III under Albert (Saxony).

Albert L'OUVRIER (French: Albert the Worker), original name ALEXANDRE MARTIN (b. April 27, 1815, Bury, Fr.—d. May 28, 1895, Mello), French worker who became the workers' representative in the provisional government and National Assembly of 1848; he was the first industrial workingman to enter a government in France.

A Paris mechanic during the 1830s and a member of several secret societies, Albert was imprisoned briefly in 1841. Subsequently, he joined the Christian-Socialist movement, collaborated on *L'Atelier* ("The Workshop"), and by 1846 had become the leader of the Society of the Seasons. When King Louis-Philippe was overthrown in February 1848, Albert was elected to the provisional government, his name appearing on all documents as Albert l'Ouvrier. With Louis Blanc he formed the extreme left contingent, advocating profound socio-economic change and supporting the short-lived Luxembourg Commission of workers and employers that reformed working hours. Elected to the new, moderate, Republican-dominated Constituent Assembly in April, Albert soon played a leading role in the May-June uprising, for which he was arrested and imprisoned. After his amnesty in 1859, he began working for a gas company and remained there for the rest of his life.

Albert OF AIX (fl. 1130), canon of the church of Aachen (Aix-la-Chapelle) and historian of the First Crusade; he gathered oral and written testaments of participants in the crusade and provided an important chronicle on the subject. Little is known about his life; he himself never visited the Holy Land. His work

was completed around 1130 and still remains the chief authority on the First Crusade and the history of the Kingdom of Jerusalem until 1120. The sole document on the People's Crusade of 1096, led by Peter the Hermit, Albert's history is a compilation of legends and eyewitness reports.

Albert OF BRANDENBURG: see Albert under Albert (Mainz).

Albert OF COLOGNE, also called ALBERT OF LAUINGEN: see Albertus Magnus, Saint.

Albert OF SAXONY, also called ALBERT OF RICMESTORP, or OF HALBERSTADT, German ALBERT VON SACHSEN, OF VON RICMESTORP, or VON HALBERSTADT (b. c. 1316, Helmstedt, Saxony—d. July 8, 1390, Halberstadt), German scholastic philosopher especially noted for his investigations into physics.

He studied at Prague and then at the University of Paris, where he was a master of arts from 1351 to 1362 and rector in 1353. Most probably he is to be identified with the Albert of Ricmestorp, or Rückmersdorf, who was rector of the University of Vienna in 1365 and bishop of Halberstadt from 1366 until his death there in 1390.

Albert based his logic on William Ockham, his physical theory on Jean Buridan, his mathematics on Thomas Bradwardine, and his ethics on Walter Burley (rejecting Buridan's psychological determinism) and was at first respected more for his clarity and exactness in exposition than for his originality. The later scholastic logicians adopted many of the terminological distinctions first found in his works, and he examined and classified 254 *sophismata* or logical paradoxes. In physics, he wrote at length on place, space, and time; on the impossibility of a plurality of worlds; and, in great detail, on the movement of bodies (Leonardo da Vinci seems to have been indebted to him on this subject). Albert gave particular attention to the problem of gravity, being perhaps the first thinker to distinguish the centre of gravity from the geometrical centre, and to that of the velocity of falling bodies, appreciating that the question was whether velocity was proportional to time or to space. He was also one of the first to understand what is now known as aerostatics, as he maintained that a light balloon would rise and remain suspended in the air if a particle of fire were enclosed in it. Finally, his search for mathematical formulas to express laws of nature foreshadowed the usage of modern physics.

Albert THE BEAR: see Albert I under Albert (Brandenburg).

Albert THE COURAGEOUS: see Albert III under Albert (Saxony).

Albert THE GREAT, SAINT: see Albertus Magnus, Saint.

Albert, Eugen (Francis Charles) d', Eugen also spelled EUGÈNE (b. April 10, 1864, Glasgow—d. March 3, 1932, Riga, Latvia), naturalized German composer and piano virtuoso best remembered for his opera *Tiefland* (1903) and his arrangements and transcriptions of the music of J.S. Bach.

After receiving his basic musical training in London, where he enjoyed his first triumphs as a pianist, d'Albert went to Vienna for further study, later becoming a pupil of Franz Liszt. D'Albert toured widely and successfully and taught for many years in Berlin, but his chief interest lay in composition. He wrote 21 operas, two piano concerti, chamber music, lieder, piano pieces, and a few orchestral works.

Albert, Heinrich (b. July 8, 1604, Lobenstein, Saxony—d. Oct. 6, 1651, Königsberg, Prussia), composer of a famous and popular collection of songs, the most representative examples of German Baroque solo song.

Albert studied composition with his cousin

Heinrich Schütz at Leipzig. His musical activities were encouraged by Johann Hermann Schein. In 1631 he became cathedral organist at Königsberg. Albert composed numerous festival pieces for the Brandenburg princes, but he is best known for his *Arien* (1638-50), settings of sacred and secular texts for voice and continuo, for some of which he also wrote the text. He also composed operas, although only two arias from these survive.

Albert, Lake, also called ALBERT NYANZA and (after 1973) LAKE MOBUTU SESE SEKO, northernmost of the lakes in the western Rift Valley system, in east central Africa, on the border between Zaire and Uganda. In 1864 the lake was first visited by a European, Samuel Baker, who was seeking the sources of the Nile; he named it after Queen Victoria's consort and published his experiences in *The Albert N'yanza* (1866). Romolo Gessi, an Italian soldier and explorer, circumnavigated it in 1876. Both Henry Stanley and Mehmed Emin Paşa (Eduard Schnitzer) established forts on its shores.

With an area of about 2,160 sq mi (5,600 sq km), a length of 100 mi (160 km), and an average width of 22 mi, Albert is a shallow body of water, averaging about 80 ft (25 m) in depth; its maximum depth is 190 ft.

In the southwest, the Semliki River brings into the lake the waters of Lake Edward (Lake Idi Amin Dada), of the Congo Escarpment, and of the rain-soaked Ruwenzori Range, building a large alluvial plain in the process. There is a considerable expanse of lowland at the northern end, where the Victoria Nile enters as a sluggish stream in a swampy delta. Almost immediately the lake narrows into the Albert Nile, through which it supplies water to the White Nile. In the west and east, the lake is bordered by forested cliffs and ravines.

Lake Albert lies at an altitude of 2,021 ft in the lowest and hottest part of Uganda. The mean annual temperature is 78° F (26° C), and rainfall averages 34-40 in. (864-1,016 mm). Because of the high rate of evaporation, the waters are somewhat saline, and free phosphate is also present. Game—including elephant, buffalo, hippopotamus, crocodile, and antelope—is abundant, especially in the Semliki Plains and the northern shores near Murchison Falls (Kabarega Falls). Fishing sustains a scanty population, located in lakeshore villages.

Albert Canal, waterway connecting the cities of Antwerp and Liège in Belgium. Completed in 1939, the Albert Canal is about 80 mi (130 km) long, has a minimum bottom width of 80 ft (24 m), and can be navigated by vessels of 2,000 tons having a maximum draft of 9 ft (2.7 m). Traversing a highly industrialized area, the canal has six sets of triple locks and one single lock at Monsin (Liège).

Albert Lea, city, seat of Freeborn County, southern Minnesota, U.S., on Fountain and Albert Lea lakes, in a mixed-farming area. Settled in 1855 and named for the U.S. Army colonel who had surveyed the region in 1835, it became the county seat in 1859 as the result of a race won by a local horse over one backed by the neighbouring town of Itasca (which no longer exists). At the crossroads of a highway and rail complex, it developed as a wholesale distribution and diversified industrial centre with large meat-packing plants. Albert Lea Area Vocational Technical Institute is in the city. Helmer Myre State Park is 2 mi (3.2 km)

east. Inc. village, 1878; city, 1927. Pop. (2000) 18,356.

Albert National Park (Zaire): *see* Virunga National Park.

Albert Nile, also called **MOBUTU NILE**, the upper Nile River in northwestern Uganda, eastern Africa, issuing from the north end of Lake Albert (Mobutu), just north of the mouth of the Victoria Nile. It flows 130 miles

The Albert Nile, near Pakwach, Uganda
Shostal—EB Inc

(210 km) north past Pakwach to the Sudanese border at Nimule, where it becomes the Al-Jabal River, or Mountain Nile. It is navigable throughout its course.

Albert Nyanza (lake, Africa): *see* Albert, Lake.

Alberta, westernmost of three Prairie Provinces, southern Canada. Alberta extends 756 miles (1,216 km) from north to south and 404 miles (650 km) from east to west and covers an area of 255,287 square miles (661,190 square km). It is bounded on the east by Saskatchewan, on the west by British Columbia, on the north by the Northwest Territories, and on the south by the United States. The provincial capital is Edmonton.

A brief treatment of Alberta follows. For full treatment, *see* **MACROPAEDIA: Canada**.

The area now known as Alberta has been inhabited by Indian groups for at least 10,000 years. In the 1750s European fur traders arrived. In the last quarter of the 18th century, two rival trading companies, the Hudson's Bay Company and the Northwest Company, began building trading posts along the Athabasca, North Saskatchewan, and Peace rivers. The companies merged in 1821. From this time until 1870, when the region was transferred to the Dominion of Canada, the Hudson's Bay Company ruled the area. European settlement increased after 1870, and the Indian population was decimated by European diseases and alcoholism. The abuses of whiskey traders brought the North West Mounted Police into the area, and in 1874 Fort Macleod was established.

In the late 19th century there was a vigorous and successful effort to increase the population. A railroad was built to Calgary, and cheap or free land was provided to newcomers. As a result, Alberta's population grew from 73,000 in 1901 to 374,000 in 1911. Many of the immigrants were employed in wheat farming.

Alberta was made a district of the Northwest Territories in 1882 and a province of Canada in 1905. The Liberal Party formed the first provincial government. Despite the discovery of oil at the town of Turner Valley in 1914, the growth of both the population and the economy slowed during World War I.

After the war there was a slump in wheat prices that contributed to agrarian political agitation. In 1921 the United Farmers Party of Alberta attained a majority in the government.

Alberta experienced the Great Depression in the 1930s, and in 1935 the Social Credit Party was elected on a platform of monetary reform. It remained in power, growing steadily more orthodox, until its defeat by the Progressive Conservative Party in 1971.

Alberta's southwestern boundary is formed by the Canadian Rockies, with Mount Columbia (12,294 feet [3,747 m]) constituting the highest of many spectacular peaks. The remainder of the province is made up of undulating plateau that ranges from more than 3,000 feet (1,000 m) to less than 1,000 feet (300 m). Northern Alberta is drained for the most part by the Athabasca, Peace, and Hay rivers, which flow by way of the Mackenzie River to the Arctic Ocean; the North and South Saskatchewan rivers and their tributaries dominate the south and direct their waters to Hudson Bay via the Saskatchewan and Nelson rivers. Alberta has a continental climate, with cold, dry winters and warm, wet summers and more sunshine than any other Canadian province. In the south, Chinook winds originating in the Rockies sometimes raise temperatures dramatically within minutes. Annual precipitation averages 18 inches (466 mm), approximately half of it falling between June and August.

The economy began to recover after World War II. Since the discovery of oil at Leduc in 1947 and the ensuing discovery of other major oil and gas deposits, there has been rapid economic expansion in Alberta. Rich natural resources include fossil fuels, timber, hydroelectric power, scenery and wildlife that stimulate tourism, and territory suitable for growing wheat and raising cattle. The ecological damage caused by these developments, however, weighed against the economic gains, has caused wide controversy.

The British North America Act (1867) and the Alberta Act (1905) provided the constitutional framework for the province. Alberta's parliamentary government consists of a unicameral legislative assembly elected by universal adult (age 18 and older) suffrage to a five-year term. The leader of the majority party becomes premier and chooses members from the assembly to form the executive council. The Canadian governor-general appoints the lieutenant governor, who serves as the monarch's representative, for a five-year term. Alberta's supreme court, whose members are appointed by the governor-general, is the highest court in the province and has both trial and appellate divisions.

Primary and secondary education is free in the public schools, and the provincial government subsidizes private religious schools. Schools for Indians are provided by the federal government. The Alberta Institutes of Technology are located in Calgary, Edmonton, and Stony Plain, and there are universities in Calgary, Lethbridge, Edmonton, and Athabasca. Provincial subsidies are available to all university students. The Banff School of Fine Arts is internationally known.

Alberta's ethnic and cultural character is one of the most varied of the Canadian provinces. The British Isles group is the largest, while other major groups include German, Ukrainian, Scandinavian, French, and Dutch. Native Indians, Polish, Austrian, Russian, Chinese, Japanese, Lebanese, and Vietnamese inhabitants are also present. This rich cultural legacy is preserved by an impressive array of museums, art galleries, and libraries. Pop. (2001) 3,064,200.

Alberta Basin, large, petroleum-rich sedimentary basin along the eastern edge of the Rocky Mountains in central Alberta, Canada. The basin was formed when the Earth's crust sank along the continental side of the Rocky Mountains during the Devonian period (408 to 360 million years ago). From that time until the Late Cretaceous period (97.5 to 66.4

million years ago), the region was covered by the sea at various intervals. Marine sediments gradually accumulated in the deepest parts of the basin, and large reefs composed of marine fossils and algae formed along its margins. Uplift of the region beginning about 65 million years ago halted sedimentation and exposed the basin deposits to erosional forces. The organic matter buried under layers of sediment and subjected to intense heat and pressure developed into oil and natural gas, which collected in the surrounding porous rock (*e.g.*, limestone reef remnants). Structural traps produced by the folding and faulting of rocks in the basin during the formation of the Rocky Mountains helped promote petroleum accumulation.

Alberti FAMILY, also called **ALBERTI DEL GIUDICE**, wealthy Florentine merchant banking family that was influential in European politics in the second half of the 14th century and notable for its patronage of the arts and beneficence toward the poor.

The ascendancy of the Alberti family began with Niccolò di Iacopo di Alberti (d. 1377), whose immense success at directing a branch of the family's bank at Avignon, Fr., then the papal seat, enabled the Alberti to become the almost exclusive banker of the papacy (1362). As codirector of the company (from 1369) and then as its director (from 1372), Niccolò steadily expanded his financial interests and increased his own and his family's wealth and influence. A strong supporter of the propapal Guelf party in Florence, he held several important public offices there, including chief magistrate, or prior (1355), and gonfalonier of justice (1363). Later he contributed to Florence's victory over the rival city of Pisa, and in a treaty in 1369 he secured free entry for Florentine ships into the port of Pisa. He built the family's magnificent Villa del Paradiso, where he protected and encouraged men of arts and letters.

Under the leadership of Benedetto (d. 1388), the Alberti sought to check the steadily growing ascendancy of the rival Albizzi family. A Guelf leader, Benedetto encouraged and participated in a popular insurrection against the oligarchic Florentine government (July 1378). Although briefly successful, this attempt ultimately failed (1382); Benedetto was exiled several years later.

Engaged also in struggles against the Albizzi was Antonio (1358–1415), who was prior (1384) and a leading patron of the arts. He maintained the Villa del Paradiso as a centre for artists, writers, and intellectuals before being banished in 1401.

In 1402 the Albizzi succeeded in having all male members of the Alberti family banished. Although allowed to return to Florence in 1428, the Alberti did not recover full civic rights until after the fall of the Albizzi in 1434. The most famous of the later Alberti was Leon Battista Alberti.

Alberti, Domenico (b. *c.* 1710, Venice [Italy]—d. 1740, Formia or Rome), Venetian composer whose harpsichord sonatas depend heavily on an accompaniment pattern of broken, or arpeggiated, chords known as the Alberti bass.

Alberti studied under the composer Antonio Lotti and was known in Rome as a singer and harpsichordist. Although he probably did not originate the Alberti bass, he consistently used it. This accompaniment pattern sets the melody against a gently moving harmonic background, satisfying the contemporary aesthetic taste for melodic predominance. It was frequently used by Joseph Haydn, Ludwig van Beethoven, and W.A. Mozart (an example is the first movement of Mozart's *Piano Sonata in C Major*, K 279) and also appears in 19th-century compositions. Alberti's sonatas were plagiarized by the singer and harpsichordist Giuseppe Jozzi.

Alberti, Leon Battista (b. Feb. 14, 1404, Genoa—d. April 25, 1472, Rome), Italian Humanist, architect, and principal initiator of Renaissance art theory. In his personality, works, and breadth of learning, he is considered the prototype of the Renaissance “universal man.”

Childhood and education. The society and class into which Alberti was born endowed him with the intellectual and moral tendencies

Leon Battista Alberti, self-portrait plaque, bronze, c. 1435; in the National Gallery of Art, Washington, D.C.

By courtesy of the National Gallery of Art, Washington, D.C. Samuel H. Kress Collection

he was to articulate and develop over a lifetime. He belonged to one of the wealthy merchant-banker families of Florence. At the time of his birth, the Alberti were in exile, expelled from Florence by the oligarchical government then dominated by the Albizzi family. Alberti's father, Lorenzo, was managing the family's concerns in Genoa, where Battista was born. Shortly thereafter he moved to Venice, where he raised Battista (Leo or Leon was a name adopted in later life) and his elder brother, Carlo. Both sons were illegitimate, the natural offspring of Lorenzo and a Bolognese widow, but they were to be Lorenzo's only children and his heirs. An affectionate and responsible father, Lorenzo provided his sons with a Florentine stepmother (whom he married in 1408), and he attended carefully to their education.

It was from his father that Battista received his mathematical training. The useful intellectual tools of the businessman inspired in him a lifelong love for the regular, for rational order, and a lasting delight in the practical application of mathematical principles. “Nothing pleases me so much,” Alberti was to have a figure in one of his dialogues remark, “as mathematical investigations and demonstrations, especially when I can turn them to some useful practice as Battista here did, who drew from mathematics the principles of painting [perspective] and also his amazing propositions on the moving of weights.” As in Leonardo da Vinci's case, mathematics led Alberti into several seemingly disparate fields of learning and practice. At one stroke, it resolved a diversity of problems and awakened an appreciation of the rational structure and processes of the physical world.

His early formal education was Humanistic. At the age of 10 or 11, Alberti was sent to boarding school in Padua. There he was given the classical Latin training that was to be denied to Leonardo, illegitimate son of a poor notary in a rustic village of Tuscany. The “new learning” was largely literary, and Alberti emerged from the school an accomplished Latinist and literary stylist. Relishing his skill as a classicist, he wrote a Latin comedy at the age of 20 that was acclaimed as the “discovered” work of a Roman playwright—and was still published as a Roman work in 1588 by the famous Venetian press of Aldus

Manutius. But it was the content rather than the form of the classical authors that absorbed Alberti as a youth and throughout his life. As for most Humanists, the literature of ancient Rome opened up for him the vision of an urbane, secular, and rational world that seemed remarkably similar to the emerging life of the Italian cities and met its cultural needs. He brought his own emotional and intellectual tendencies to “the ancients,” but from them he drew the conceptual substance of his thought.

Alberti completed his formal education at the University of Bologna in an apparently joyless study of law. His father's death and the unexpected seizure of his legacy by certain members of the family brought him grief and impoverishment during his seven-year stay at Bologna, but he persisted in his studies. After receiving his doctorate in canon law in 1428, he chose to accept a “literary” position as a secretary rather than pursue a legal career. By 1432 he was a secretary in the Papal Chancery in Rome (which supported several Humanists), and he had a commission from a highly placed ecclesiastical patron to rewrite the traditional lives of the saints and martyrs in elegant “classical” Latin. From this point on, the church was to provide him with his livelihood. He took holy orders, thus receiving in addition to his stipend as a papal secretary an ecclesiastical benefice, the priory of Gangalandi in the diocese of Florence, and some years later Nicholas V conferred upon him as well the rectory of Borgo San Lorenzo in Mugello. Although he led an exemplary, and apparently a celibate, life, there is almost nothing in his subsequent career to remind one of the fact that Alberti was a churchman. His interests and activities were wholly secular and began to issue in an impressive series of Humanistic and technical writings.

Contribution to philosophy, science, and the arts. The treatise “Della famiglia” (“On the Family”), which he began in Rome in 1432, is the first of several dialogues on moral philosophy upon which his reputation as an ethical thinker and literary stylist largely rests. He wrote these dialogues in the vernacular, expressly for a broad urban public that would not be skilled in Latin: for the *non litteratissimi cittadini*, as he called them. Based upon classical models, chiefly Cicero and Seneca, these works brought to the day-to-day concerns of a bourgeois society the reasonable counsel of the ancients—on the fickleness of fortune, on meeting adversity and prosperity, on husbandry, on friendship and family, on education and obligation to the common good. They are didactic and derivative, yet fresh with the tone and life-style of the Quattrocento (the 1400s). In Alberti's dialogues the ethical ideals of the ancient world are made to foster a distinctively modern outlook: a morality founded upon the idea of work. Virtue has become a matter of action, not of right thinking. It arises not out of serene detachment but out of striving, labouring, producing.

This ethic of achievement, which corresponds to the social reality of his youth, found ready acceptance in the urban society of central and northern Italy in which Alberti moved after 1434. Travelling with the papal court of Eugenius IV to Florence (the ban of exile against his family was lifted with the restoration of Medici influence), Bologna, and Ferrara, Alberti made several congenial and fruitful contacts. The writings, both the Latin and vernacular ones, that he dedicated to his new associates are imbued with his characteristic notions of work, practice, and productive activity; and he took upon himself in turn the technical and practical problems that were absorbing his friends and patrons. In Florence his close associations with the sculptor Donatello and the architect Brunelleschi led to one of his major achievements: the systematization of the painter's perspective. The book *On Painting*, which he wrote in 1435, set

forth for the first time the rules for drawing a picture of a three-dimensional scene upon the two-dimensional plane of a panel or wall. It had an immediate and profound effect upon Italian painting and relief work, giving rise to the correct, ample, geometrically ordered space of the perspectival Renaissance style. Later perspectival theorists, such as the painter Piero della Francesca and Leonardo, elaborated upon Alberti's work, but his principles remain as basic to the projective science of perspective as Euclid's do to plane geometry.

His friendship with the Florentine cosmographer Paolo Toscanelli was of comparable practical and scientific importance. It was Toscanelli who provided Columbus with the map that guided him on his first voyage. Alberti seems to have collaborated with him in astronomy rather than geography, but the two sciences were closely bound at the time (and bound to perspective) by the conceptions and methods of geometric mapping rediscovered in the writings of the ancient astronomer and geographer Ptolemy. Alberti's distinctive contribution to this current of thought took the form of a small treatise on geography, the first work of its kind since antiquity. It sets forth the rules for surveying and mapping a land area, in this case the city of Rome, and it was probably as influential as his earlier treatise on painting. Although it is difficult to trace the historical connections, the methods of surveying and mapping and the instruments described by Alberti are precisely those that were responsible for the new scientific accuracy of the depictions of towns and land areas that date from the late 15th and early 16th centuries.

At the Este court in Ferrara, where Alberti was first made a welcome guest in 1438, the Marchese Leonello encouraged (and commissioned) him to direct his talents toward another field of endeavour: architecture. Alberti's earliest effort at reviving classical forms of building still stands in Ferrara, a miniature triumphal arch that supports an equestrian statue of Leonello's father. Leonello inspired a great Humanistic undertaking as well as a mode of artistic practice on Alberti's part by urging him to restore the classic text of Vitruvius, architect and architectural theorist of the age of the Roman emperor Augustus. With customary thoroughness, Alberti embarked upon a study of the architectural and engineering practices of antiquity that he continued when he returned to Rome in 1443 with the papal court. By the time Nicholas V became pope in 1447, Alberti was knowledgeable enough to become the Pope's architectural adviser. The collaboration between Alberti and Nicholas V gave rise to the first grandiose building projects of Renaissance Rome, initiating among other works the reconstruction of St. Peter's and the Vatican Palace. As the Este prince was now dead, it was to Nicholas V that Alberti dedicated in 1452 the monumental theoretical result of his long study of Vitruvius. This was his *De re aedificatoria* (*Ten Books on Architecture*), not a restored text of Vitruvius but a wholly new work, that won him his reputation as the “Florentine Vitruvius.” It became a bible of Renaissance architecture, for it incorporated and made advances upon the engineering knowledge of antiquity, and it grounded the stylistic principles of classical art in a fully developed aesthetic theory of proportionality and harmony.

During the final 20 years of his life, Alberti carried out his architectural ideas in several outstanding buildings. The facades of Sta. Maria Novella and the Palazzo Rucellai, both executed in Florence for the merchant Giovanni Rucellai, are noted for their proportionality, their perfect sense of measure. They are worthy successors to the art of Brunelleschi,

initiator of the Florentine Quattrocento style of architecture. Other buildings look forward to the 16th century, particularly to Donato Bramante, the architect of St. Peter's. The classical severity of Alberti's Tempio Malatestiano, commissioned by Sigismondo Malatesta, the ruler of Rimini, and the new sense of volume and amplitude of the majestic Church of San Andrea, which he designed for Ludovico Gonzaga, the Humanist Marquess of Mantua, announce the fullness of the High Renaissance style. Alberti was not only the foremost theorist of Renaissance architecture; he had become one of its great practitioners as well.

Architecture preoccupied him during the 1450s and 1460s, and he traveled a great deal to the various cities and courts of Renaissance Italy, but Rome and Florence remained his intellectual homes, and he continued to cultivate the interests they had always stimulated. In Rome, where republican life was precluded by the papal government, he was absorbed by technical and scientific matters. His response to certain problems entertained by members of the Papal Chancery led to two highly original works in this category. One is a grammar book, the first Italian grammar, by which he sought to demonstrate that the Tuscan vernacular was as "regular" a language as Latin and hence worthy of literary use. The other is a pioneer work in cryptography: it contains the first known frequency table and the first polyalphabetic system of coding by means of what seems to be Alberti's invention, the cipher wheel. Although he had been dismissed from the Papal Chancery in 1464 because of the retrenchment ordered by Pope Paul II, Alberti undertook this study, of obvious importance to the papacy, at the request of a friend who stayed on as a papal secretary.

In all his projects, Alberti employed his intellectual gifts in some "useful" work—useful to the artistic, cultivated, and courtly circles in which he moved, including painters and builders, mapmakers and astronomers, Humanists, princes, and popes. In all of his work, his versatility remained bound to the social outlook that characterized the "civic Humanism" of Florence.

It is fitting that his final and finest dialogue should be set in Florence and be written in the clear Tuscan prose he had helped to regularize and refine. Although the republicanism of Florence was now eclipsed, and Alberti now moved as a familiar in the circle of the princely Lorenzo de' Medici, *De iciarchia* ("On the Man of Excellence and Ruler of His Family") represents in full flower the public-spirited Humanism of the earlier bourgeois age to which he belonged. Alberti is its chief protagonist, and no more appropriate figure is conceivable. For this dialogue, more than any other, celebrates the union of theory and practice that Florentine Humanism had attained and the ethic of achievement and public service that he himself had come to exemplify. *De iciarchia* was completed just a few years before his death. He died "content and tranquil," according to the 16th-century biography by Giorgio Vasari.

Assessment. Alberti was in the vanguard of the cultural life of early Renaissance Italy. He has been admired for his many-sided nature, as has Leonardo da Vinci, who followed him by half a century and resembles him in this respect. Yet in Alberti's case, unity as much as versatility typifies the man and his accomplishments. Leonardo's genius carried him further than Alberti: he saw more and saw more deeply. But Leonardo's vision has a "modern," fragmentary character, whereas Alberti attained a completeness in thought and life that fulfilled the Renaissance ideals of measure and harmony. His intellectual and

artistic pursuits were all of a piece, and he struck a unique balance between theory and practice, realizing this dominant aspiration of his age at the very moment social and political events had begun to cause it to fade.

(J.K.-G.)

MAJOR WORKS. *Architecture.* Palazzo Rucellai, Florence (c. 1445-51); S. Francesco, Tempio Malatestiano, Rimini (1447-50); facade, Sta. Maria Novella, Florence (1456-70); S. Sebastiano, Mantua (1460-70); Rucellai Chapel, Florence (1467); S. Andrea, Mantua (c. 1470); SS. Annunziata, Florence (designed c. 1470).

Writings. *Della famiglia* (written 1435-44); *De pictura praestantissima* (1435); *Della pittura* (1436); *On Painting*, 1956; *De re aedificatoria* (promulgated in 1452; published in 1485; *Ten Books on Architecture*, 1955); *De iciarchia* (1468).

BIBLIOGRAPHY. A comprehensive introduction to Alberti's life and work is offered in Joan Kelly-Gadol, *Leon Battista Alberti: Universal Man of the Early Renaissance* (1969, reprinted 1973). Franco Borsi, *Leon Battista Alberti* (1977, reissued 1989), is a broad and excellently illustrated treatment by a historian of architecture. An in-depth study of the cultural and social background of Alberti's architectural endeavors is found in Carroll William Westfall, *In This Most Perfect Paradise: Alberti, Nicholas V, and the Invention of Conscious Urban Planning in Rome, 1447-55* (1974). The following studies of some of the fields in which Alberti worked give interesting appraisals of the contributions he made to them: David Kahn, *The Codebreakers. The Story of Secret Writing* (1967); Erwin Panofsky, *Renaissance and Renascences in Western Art*, 2 vol. (1960, reissued 1972); Rudolf Wittkower, *Architectural Principles in the Age of Humanism*, 4th ed. (1973, reissued 1988); William Harrison Woodward, *Studies in Education During the Age of the Renaissance, 1400-1600* (1906, reissued 1965).

Alberti, Rafael (b. Dec. 16, 1902, Puerto de Santa María, Spain—d. Oct. 28, 1999, Puerto de Santa María), Spanish writer of Italian-Irish ancestry, regarded as one of the major Spanish poets of the 20th century.

Alberti studied art in Madrid and enjoyed some success as a painter before 1923, when he began writing and publishing poems in magazines. His first book of poetry, *Marinero en tierra* (1925; "Sailor on Land"), recalled the sea of his native Cádiz region and won a national prize. A member of the so-called Generation of 1927, Alberti helped to celebrate the tercentenary of Luis de Góngora in 1927, and Góngorist influence is apparent in the work published in that period, *El alba del alhelí* (1927; "The Dawn of the Wallflower") and *Cal y canto* (1928; "Quicklime and Song"). With his next book, however, the somewhat Surrealist *Sobre los ángeles* (1929; *Concerning the Angels*), Alberti established himself as a mature and individual voice.

In the 1930s Alberti's work became overtly political; he wrote plays, traveled widely, joined the Communist Party—from which he was later expelled—and founded a review, *Octubre*. He fought for the Republic in the Spanish Civil War and afterward fled to Argentina, where he worked for the Losado publishing house and resumed both his poetry and his earlier interest—painting. In 1941 he published a collection of poems, *Entre el clavel y la espada* ("Between the Carnation and the Sword"), and in 1942 his autobiography, *La arboleda perdida* (*The Lost Grove*), and a book of drama, prose, and poetry about the Civil War, *De un momento a otro* ("From One Moment to Another"). He published a collection of poems inspired by painting, *A la pintura* (1945; "On Painting"), and collections on maritime themes, such as *Pleamar* (1944; "High Tide"). After 1961, he lived in Italy until he returned to Spain in 1977.

Albertina Graphics Collection, German GRAPHISCHE SAMMLUNG ALBERTINA, compilation of graphic arts in the Hofburg, or Imperial Palace, of Vienna, Austria. It is important

for its comprehensive collection of prints, drawings, sketchbooks, and miniatures assembled in the 18th century by Albert Kasimir, Duke of Saxe-Teschen, and cataloged by Adam von Bartsch. The extraordinary quantity and quality of prints in this collection induced Bartsch to go one step further and establish *oeuvre* catalogs (inventories of works produced by an artist) of the masters of printmaking. The collection was administered by Albert's successors until 1920, when it was taken over by the government of Austria. The collection centres on European drawings and prints from the 15th to the 20th century.

Albertinelli, Mariotto (b. 1474, Florence [Italy]—d. 1515, Florence), painter associated with Fra Bartolomeo, and an artist whose style upheld the principles of the High Renaissance in Florence a decade after its leading exponents had moved to Rome.

Albertinelli and Bartolomeo were fellow pupils and later painted many works together. Albertinelli's chief paintings are in Florence, notably his masterpiece, the "Visitation of the Virgin" (1503; Uffizi). His style, similar to Bartolomeo's, is characterized by simple dignity and monumentality and shows particularly the influence of Leonardo da Vinci in its aristocratic, smiling figures, intimate compositions, and strong contrast of light and dark.

Albertini, Luigi (b. Oct. 19, 1871, Ancona, Italy—d. Dec. 29, 1941, Rome), Italian journalist, an early and outspoken opponent of Fascism, who made the *Corriere della sera* (in Milan) one of the most respected and widely read daily newspapers in Europe.

As a young man, Albertini lived in London, where he investigated labour conditions and studied the organization of *The Times*. Becoming business manager (1898) and editor (1900) of the *Corriere della sera*, he installed modern equipment and brought the paper's technical services up to date. Through the *Corriere* he defended individual freedoms and governmental authority, regarding both as necessary.

Not a doctrinaire patriot, he favoured Italy's entry into World War I but disapproved of the poet and violent Italian nationalist Gabriele D'Annunzio's freebooting capture of Fiume (now Rijeka, Croatia) in September 1919 and the Italian annexations in Dalmatia. He supported the agreement of Rapallo (November 1920) between Yugoslavia and Giovanni Giolitti's Italian government. Although Albertini had criticized the earlier postwar governments in Italy for their weakness, he was not reassured by the more forceful regime of Fascism and was one of the few newspaper editors to resist Fascist threats and cajolery. In November 1925, because of his stand against the government, the owners of the *Corriere* dismissed him.

Albertini devoted the rest of his life to historical studies and to land reclamation on his model estate at Torrioni, near Rome. He

had been a senator since 1914. His major studies, including *Le origini della guerra del 1914*, 3 vol. (1942–43; *The Origins of the War of 1914*), were published posthumously.

Albertosaurus, formerly *GORGOSAURUS*, genus of large carnivorous dinosaurs found as fossils in Late Cretaceous deposits (97.5 to 66.4 million years ago) of North America and eastern Asia. *Albertosaurus* had a large skull and jaws bearing numerous large, sharp

teeth. *Albertosaurus* was a biped with well-developed hind limbs and supporting triangular pelvis. The tail was long and well-developed and served as a counterbalance to the body. *Albertosaurus* was about 9 m (30 feet) long; the head stood 3.5 m (11 feet) off the ground. In life *Albertosaurus* probably moved slowly with a stooped pose. It is possible that *Albertosaurus* was at least in part a scavenger, feeding upon dead or dying carcasses of other reptiles. In structure and presumed life habits, *Albertosaurus* was probably similar to *Tyrannosaurus*, although smaller. *Albertosaurus* fossils occur in rocks that are slightly older than those containing *Tyrannosaurus* fossils.

Albertosaurus

working on a monumental presentation of the entire body of knowledge of his time. He wrote commentaries on the Bible and on the *Sentences*; he alone among medieval scholars made commentaries on all the known works of Aristotle, both genuine and spurious, paraphrasing the originals but frequently adding “digressions” in which he expressed his own observations, “experiments,” and speculations. The term experiment for Albertus indicates a careful process of observing, describing, and classifying. His speculations were open to Neoplatonic thought. Apparently in response to a request that he explain Aristotle’s *Physics*, Albertus undertook—as he states at the beginning of his *Physica*—“to make . . . intelligible to the Latins” all the branches of natural science, logic, rhetoric, mathematics, astronomy, ethics, economics, politics, and metaphysics. While he was working on this project, which took about 20 years to complete, he probably had among his disciples Thomas Aquinas, who arrived at Paris late in 1245.

Albertus distinguished the way to knowledge by revelation and faith from the way of philosophy and of science; the latter follows the authorities of the past according to their competence, but it also makes use of observation and proceeds by means of reason and intellect to the highest degrees of abstraction. For Albertus these two ways are not opposed; there is no “double truth”—one truth for faith and a contradictory truth for reason. All that is really true is joined in harmony. Although there are mysteries accessible only to faith, other points of Christian doctrine are recognizable both by faith and by reason—*e.g.*, the doctrine of the immortality of the individual soul. He defended this doctrine in several works against the teaching of the Averroists (Latin followers of Averroës), who held that only one intellect, which is common to all human beings, remains after the death of man.

Albertus’ lectures and publications gained him great renown. He came to be quoted as readily as the Arabian philosophers Avicenna and Averroës and even Aristotle himself. Roger Bacon, a contemporary English scholar who was by no means friendly toward Albertus, spoke of him as “the most noted of Christian scholars.”

In the summer of 1248, Albertus was sent to Cologne to organize the first Dominican *studium generale* (“general house of studies”) in Germany. He presided over the house until

of “Teutonia,” the German province of the Dominicans. Although burdened with added administrative duties, he continued his writing and scientific observation and research. Albertus resigned the office of provincial in 1257 and resumed teaching in Cologne. In 1259 he was appointed by the pope to succeed the bishop of Regensburg, and he was installed as bishop in January 1260. After Alexander IV died in 1261, Albertus was able to resign his episcopal see. He then returned to his order and to teaching at Cologne. From 1263 to 1264 he was legate of Pope Urban IV, preaching the crusade throughout Germany and Bohemia; subsequently, he lectured at Würzburg and at Strasbourg. In 1270 he settled definitively at Cologne, where, as he had done in 1252 and in 1258, he made peace between the archbishop and his city.

During his final years he made two long journeys from Cologne. In 1274 he attended the second Council of Lyon, France, and spoke in favour of acknowledging Rudolf of Habsburg as German king. In 1277 he traveled to Paris to uphold the recently condemned good name and writings of Thomas Aquinas, who had died a few years before, and to defend certain Aristotelian doctrines that both he and Thomas held to be true.

Albertus’ works represent the entire body of European knowledge of his time not only in theology but also in philosophy and the natural sciences. His importance for medieval science essentially consists in his bringing Aristotelianism to the fore against reactionary tendencies in contemporary theology. On the other hand, without feeling any discrepancy in it, he also gave the widest latitude to Neoplatonic speculation, which was continued by Ulrich of Strasbourg and by the German mystics of the 14th century. It was by his writings on the natural sciences, however, that he exercised the greatest influence. Albertus must be regarded as unique in his time for having made accessible and available the Aristotelian knowledge of nature and for having enriched it by his own observations in all branches of the natural sciences. A preeminent place in the history of science is accorded to him because of this achievement.

BIBLIOGRAPHY. Studies of Albertus’ life and work include Thomas M. Schwertner, *St. Albert the Great* (1932); James A. Weisheipl (ed.), *Albertus Magnus and the Sciences* (1980); and Francis J. Kovach and Robert W. Shahan (eds.), *Albert the Great: Commemorative Essays* (1980).

Albertville (Zaire): see Kalemie.

Albi, city, capital of Tarn *département*, Midi-Pyrénées region, in the Languedoc, southern France. It lies along the Tarn River where the latter leaves the Massif Central for the Garonne Plain, northeast of Toulouse. Albi, or Albige, was the capital of the Gallo-Roman Albigenes and later of the viscounty of Albigeois, which was a fief of the counts of Toulouse. An active centre of Catharism, the town gave its name to the Albigensian heresy, which led to the Albigensian Crusade (1209) and later to the development of the Inquisition. The city was captured in 1215, and the bishops subsequently lost their estates to the crown. By a convention (1264), temporal power was granted to the bishops (archbishops after 1678) until the French Revolution.

The town’s most important architectural glory is the Gothic Sainte-Cécile Cathedral (1277–1512), which was constructed in brick, without flying buttresses. Between the cathedral and the river is situated the red brick Berbie Palace, a 13th-century archbishop’s palace that is now a museum where the works of Henri de Toulouse-Lautrec, a native of Albi, are displayed. Below the palace is the 9th-century Old Bridge. The centre of the town

town also manufactures cement, dyes, flour, synthetic textiles, and glass. Pop. (1982) 42,724.

Albigenses, also called **ALBIGENSIANS**, the heretics—especially the Catharist heretics—of 12th–13th-century southern France. (See Cathari.) The name, apparently given to them at the end of the 12th century, is hardly exact, for the movement centred at Toulouse and in nearby districts rather than at Albi (ancient Albica). The heresy, which had penetrated into these regions probably by trade routes, came originally from eastern Europe.

It is exceedingly difficult to form any very precise idea of the Albigensian doctrines because present knowledge of them is derived from their opponents and from the very rare and uninformative Albigensian texts which have come down to us. What is certain is that, above all, they formed an antisacerdotal party in permanent opposition to the Roman church and raised a continued protest against the corruption of the clergy of their time. The Albigensian theologians and ascetics, known in the south of France as *bons hommes* or *bons chrétiens*, were always few in number.

The first Catharist heretics appeared in Limousin between 1012 and 1020. Protected by William IX, duke of Aquitaine, and soon by a great part of the southern nobility, the movement gained ground in the south, and in 1119 the Council of Toulouse in vain ordered the secular powers to assist the ecclesiastical authority in quelling the heresy. The people were attached to the *bons hommes*, whose asceticism and antisacerdotal preaching impressed the masses, and the movement maintained vigorous activity for another 100 years, until Innocent III ascended the papal throne. At first he tried pacific conversion but at last (1209) ordered the Cistercians to preach the crusade against the Albigenses. This implacable war, the Albigensian Crusade, which threw the whole of the nobility of the north of France against that of the south and destroyed the brilliant Provençal civilization, ended, politically, in the Treaty of Paris (1229), which destroyed the independence of the princes of the south but did not extinguish the heresy, in spite of the wholesale massacres of heretics during the war. The Inquisition, however, operating unremittingly in the south at Toulouse, Albi, and other towns during the 13th and 14th centuries, succeeded in crushing it.

albinism (from the Latin *albus*, meaning "white"), the absence of pigment in the eyes, skin, hair, scales, or feathers. Albino animals rarely survive in the wild because they lack the pigments that normally provide protective coloration and screen against the sun's ultra-violet rays.

Albinism is a hereditary condition in humans and other vertebrates. In generalized, or total albinism, the affected person has milk-white skin and hair, though the skin may be slightly pinkish in colour owing to underlying blood vessels. The iris of the eye appears pink, while the pupil itself appears red from light reflected by blood in the unpigmented choroid. Vision abnormalities such as astigmatism, nystagmus (rapid involuntary oscillation of the eye), and photophobia (extreme sensitivity to light) are common. Albinos sunburn very easily and are thus more susceptible to skin cancers.

Generalized albinism is caused by the absence of melanin, the dark brown pigment normally present in the human skin, hair, and eyes. Albinism arises from a genetic defect resulting in the body's inability to synthesize tyrosinase, an enzyme that is necessary for the production of melanin. When the gene for the production of tyrosinase is absent and the gene for no production of the enzyme is present in a double form, albinism will result. Human albinism is transmitted as an autosomal recessive trait. Generalized albinism occurs in all races in about one in 20,000 persons.

A related disease is vitiligo, in which localized areas of the skin lack pigment and resemble that of an albino, while elsewhere on the body the pigmentation is normal.

Albino, colour type of horse, characterized by pink skin and a pure white coat. Unlike some other colour types, which develop as the horse matures, the Albino is born white and remains white throughout life. Albinos conform to riding horse type. They are not true biological albinos, however, as they have blue or sometimes brown eyes rather than pink. The American Albino Horse Club, which registers Albinos on the basis of colour, was organized on White Horse Ranch in Nebraska.

Albinoni, Tomaso Giovanni (b. June 8/14, 1671, Venice [Italy]—d. Jan. 17, 1750/51, Venice), Italian composer remembered chiefly for his instrumental music.

The son of a wealthy paper merchant, Albinoni enjoyed independent means. Although he was a fully trained musician, he considered himself an amateur. Little is known of his life, except for the production of more than 50 of his operas, chiefly at Venice between 1694 and 1741. Albinoni also published nine sets of instrumental works, which achieved wide

popularity in his own day and are still appreciated today. (Johann Sebastian Bach based four of his own keyboard fugues on themes composed by Albinoni.) Especially notable are the *Sinfonie e Concerti a 5* (Opus 2, 1707), the concerti for solo violin (Opus 5, 1710), and the concerti for one and two oboes in Opus 7 and Opus 9. These works are distinguished by their urbanity and charm.

Albinovanus Pedo (fl. early 1st century AD), Roman poet who wrote a *Thesaid*, referred to in a letter from his friend the poet Ovid; epigrams that are commended by the Latin poet Martial; and an epic poem on the military exploits of the Roman general Germanicus Caesar, the emperor Tiberius' adopted son, under whom Pedo probably served. This epic may have been used as a source by the Roman historian Tacitus. All that remains of Pedo's works is a beautiful fragment, preserved in the *Suasoriae* of Seneca the Elder, that describes the voyage of Germanicus (AD 16) through the Ems River to the Northern Ocean.

Albinus, Decimus Clodius Septimius (d. AD 197), Roman general, a candidate for the imperial title in the years 193–197. He represented the aristocracy of the Latin-speaking West, in contrast to Pescennius Niger, candidate of the Greek-speaking East, and to Lucius Septimius Severus, candidate of the army and of the Balkan region.

Originally from Hadrumetum in Roman Africa (now Sousse, Tur.), Albinus became a senator, evidently in the last years of the reign of the emperor Marcus Aurelius. Soon after 180 Albinus distinguished himself in a campaign somewhere north of Dacia (now in Romania). He was consul in the late 180s and commanded armies on the Rhine and (about 191) in Britain.

Early in 193, after the murder of the emperor Pertinax, the guards in Rome proclaimed M. Didius Salvidianus emperor; evidence suggests that Albinus may have encouraged Didius. The armies of the Danube and of Syria, however, proclaimed imperial power for their respective commanders, Severus and Niger. Didius was murdered, and Severus, entering Rome as emperor, concluded with Albinus an agreement that acknowledged him as caesar and heir. After Niger was destroyed by Severus, a rupture between the two re-

Albinus, marble bust by an unknown artist; in the Vatican Museum

Alinari—Art Resource/EB Inc

maining rivals was inevitable. In 197, Albinus, now proclaimed emperor, entered Gaul and advanced toward Rome with the army of Britain. Severus marched through southern Germany and defeated and killed Albinus in a two-day battle that took place outside modern Lyon, Fr.

Albinus, Decimus Junius Brutus: see Brutus Albinus, Decimus Junius.

Albion, the earliest-known name for the island of Britain. It was used by ancient Greek geographers from the 4th century BC and even earlier, who distinguished "Albion" from Ierne (Ireland) and from smaller members of the British Isles. The Greeks and Romans probably received the name from the Gauls or the Celts. The name Albion has been translated as "white land"; and the Romans explained it as referring to the chalk cliffs at Dover (Latin *albus*, "white").

albite, common feldspar mineral, a sodium aluminosilicate ($\text{NaAlSi}_3\text{O}_8$) that occurs most widely in pegmatites and acidic igneous rocks such as granites. It may also be found in low-grade metamorphic rocks and as authigenic albite in certain sedimentary varieties. Albite usually forms brittle, glassy crystals that may be colourless, white, yellow, pink, green, or black. It is used in the manufacture of glass and ceramics, but its primary geologic importance is as a rock-forming mineral.

Albite constitutes the sodium end-member of the plagioclase feldspar solid solution series and alkali feldspar series (see plagioclase; alkali feldspar). It has a triclinic framework structure with silicon and aluminum in tetrahedral (fourfold) coordination, which forms relatively large void spaces (i.e., crystallographic sites) occupied chiefly by sodium cations. At low temperatures the silicon and aluminum atoms are distributed in a highly ordered fashion, but at high temperatures (about $1,100^\circ\text{C}$ [$2,000^\circ\text{F}$]), the atoms have a much more random distribution. For detailed treatment of the physical properties of albite, see feldspar (table).

Albizia, also spelled ALBIZZIA, large genus of trees, of the pea family (Fabaceae), native to warm regions of the Old World. The alternate, compound leaves are bipinnate (i.e., the leaflets of the feather-formed leaves, in turn, bear leaflets). The small flowers are borne in

Silk, or mimosa, tree (*Albizia julibrissin*)

Grant Heilman

globular or finger-shaped clusters. The fruit is a large, strap-shaped pod. Several species are grown as ornamentals. *A. julibrissin*, or *julibrissin* (silk tree, or mimosa tree), native to Asia and the Middle East, grows to about 9 m (30 feet) tall, has a broad, spreading crown, and bears flat pods about 12 cm (5 inches) long. *A. lebbek* (sirir, or woman's-tongue tree), native to tropical Asia and Australia, grows about 24 m tall and bears pods 23–30 cm long. *A. lophantha* (plume albizia), native to Australia, grows to about 6 m tall and has pods 7.5 cm long.

Albo, Joseph (b. c. 1380, Monreal?, Aragon [Spain]—d. c. 1444), Jewish philosopher and theologian of Spain who is noted for his classic work of Jewish dogmatics, *Sefer ha-'iqqarim* (1485; "Book of Principles").

Little is known of Albo's life. He is known to have participated in the Disputation of Tortosa (1413–14), a definitive confrontation between Spanish Jews and Christians, in which he distinguished himself by his ability to explain Jewish scriptures. The *Sefer ha-'iqqarim*, completed in Castile about 1425 (although not published for some 60 years), was probably intended as a work of Jewish apologetics, i.e., a defense of Judaism against criticism of it by other religious groups—in this case, Christians. In this work Albo sought to enumerate those fundamental dogmas or articles of faith of Judaism that are essentially derived from the divine law and can thus be eternally valid for other religions as well. *Sefer Ha-ikkarim* (1929–30), edited and translated by Isaac Husik, was the first translation into English.

Alboin (d. June 28, 572, Verona, Lombardy [Italy]), king of the Germanic Lombards whose exceptional military and political skills enabled him to conquer northern Italy.

When Alboin succeeded his father, Audoin, about 565, the Lombards occupied Noricum and Pannonia (now in Austria and western Hungary), while their long-standing enemies the Gepidae bordered them on the east in Dacia (now Hungary). Astutely allying himself with the Avars, the eastern neighbours of the Gepidae, Alboin crushed his foes in a pincer movement, himself killing their king, Cunimund. After the death of his first wife, he forced Cunimund's daughter Rosamund to marry him.

Having absorbed the surviving Gepidae into the Lombard nation, Alboin assembled adventurers from all the other Germanic tribes, including several thousand Saxons, and prepared his combined forces, together with their women and children, for a migration across the Alps into Italy, which was held at that time by the Byzantines. The severely disorganized and generally unprepared provinces in northern Italy offered little resistance to the invading Lombards. Having swept through Venice, Milan, Tuscany, and Benevento, Alboin established Pavia, on the Ticino River, as the capital of the newly created Lombard kingdom in 572. According to tradition, Alboin was assassinated by order of his wife Rosamund after he had forced her to follow the Lombard custom of drinking from the skull of her slain father.

Alboni, Marietta, original name MARIA ANNA MARZIA (b. March 6, 1823, Città di Castello, Papal States [Italy]—d. June 23, 1894, Ville d'Avray, near Paris, Fr.), Italian operatic contralto known for her classic Italian bel canto.

While a student at Bologna, Alboni captured the attention of Gioacchino Rossini, who later was to instruct her in the main contralto roles in his operas. In 1842 she made her debut as Climene in Giovanni Pacini's *Saffo* at Bologna, and she achieved a notable success in Rossini's *Le siège de Corinthe* at La Scala in Milan. She toured Austria (1843), Russia (1844–45), and Germany and eastern Europe (1846). In 1847 Alboni made sensational English and French debuts at Covent Garden in London and the Théâtre-Italien in Paris in Rossini's *Semiramide*. In 1852–53 Alboni toured Spain and the United States to great acclaim. She married, settled in Paris, sang at Rossini's funeral in 1868, and retired because of her worsening obesity, making her final appearance in 1872.

Alboni avoided rehearsing to save her voice, which remained beautiful well into her middle age. Because of the paucity of contralto parts, she also sang soprano roles and even male roles, such as the title role in *Don Carlos*.

Ålborg, also spelled AALBORG, city, port, and seat of Nordjylland *amtskommune* (county commune), northern Jutland, Denmark, on

the south side of Limfjorden. It has existed since about AD 1000 and is one of the oldest towns in Denmark. Chartered in 1342, it became a bishop's see in 1554. The town

The Viking burial ground at Lindholm Høje, near Ålborg, Den.

Inga Austrup

recovered slowly from the Count's War (a religious civil war, 1533–36) to become a major commercial centre in the 17th century and was Denmark's second largest city until about 1850. It is the site of the Danish surrender (1629) to Albrecht von Wallenstein (the Roman Catholic commander) during the Thirty Years' War. Ålborg has shipbuilding facilities, and its manufactures include cement, tobacco, chemicals, textiles, and spirits, notably *akvavit*, the fiery Danish national drink. Ålborghallen (1953) is Scandinavia's largest conference and concert complex.

Medieval landmarks include the Holy Ghost Monastery (1431), the Budolfi Church (cathedral; c. 1500), and Ålborghus (castle; 1539). The Ålborg art and historical museum houses relics from the Viking ship cemetery at nearby Lindholm Hills. The Rebild Hills National Park (1912), 19 miles (31 km) south, a gift from Americans of Danish descent, is the site of the Udvandrer-Museum (Emigration Museum). The University Centre of Ålborg opened in 1974. Pop. (1982 est.) city, 114,970; (1983 est.) mun., 157,270.

Albornoz, Gil Álvarez Carrillo de (b. c. 1310, Cuenca, Castile [Spain]—d. Aug. 23/24, 1367, Viterbo, Papal States [Italy]), Spanish cardinal and jurist who paved the way for the papacy's return to Italy from Avignon, France (where the popes lived from about 1309 to 1377).

Albornoz was first a soldier, then entered the church and became archbishop of Toledo in 1338. He supported the campaigns of Castile's King Alfonso XI against the Muslims, and his achievements attracted the notice of the papal curia in Avignon. Pope Clement VI appointed him cardinal in 1350. Under Pope Innocent VI he was made legate (1353–57) and vicar-general of Italy with orders to subdue the individual feudal lords and despots who then effectively controlled the Papal States. He was surprisingly successful in his campaigns against them, and by 1357 he felt free to return to Avignon, where his *Liber constitutionum Sanctae Matris Ecclesiae* ("Book of the Constitution of Holy Mother Church"), also known as the *Constitutiones aegidianae*, was published. This legal code, or constitution, remained in force in the Papal States until the early 19th century.

In 1358 Albornoz was made papal legate again and sent back to Italy to eliminate the two remaining obstacles to the papacy's return there. He eradicated the Free Companies, or bands of mercenaries, and he recovered Bologna from the Milanese family of Visconti

in 1364. The Papal States were thus reunited, and it seemed safe for the pope to return to Rome, which Urban V did in 1367 on a visit. Urban V also made Albornoze legate of Bologna, where he founded the university for young Spaniards that today bears his name.

Albrecht (German personal name): *see under* Albert.

Albrechtsberger, Johann Georg (b. Feb. 3, 1736, Klosterneuburg, near Vienna, Austrian Habsburg domain [now in Austria]—d. March 7, 1809, Vienna), Austrian composer, organist, and music theorist who was one of the most learned and skillful contrapuntists of his time. His fame attracted many pupils, including Ludwig van Beethoven.

Albrechtsberger studied organ and thorough bass with Leopold Pittner and from 1755 to 1766 held various posts as organist. In 1772 he was appointed deputy court organist in Vienna, succeeded Mozart as an assistant Kapellmeister at St. Stephen's Cathedral after the latter's death in 1791, and became full Kapellmeister in 1793. One of the finest organists of his day, he was also an influential teacher who trained a generation of Viennese musicians, including Beethoven, Carl Czerny, and Johann Nepomuk Hummel.

Of Albrechtsberger's more than 750 compositions, most remain in manuscript. They include 35 masses, 240 fugues for various instruments, many string quartets and two-movement sonatas, and other religious and chamber music. His main theoretical work, *Gründliche Anweisung zur Composition* (1790; "Fundamentals of Composition"), was based mainly on earlier works by Johann Joseph Fux and Friedrich Wilhelm Marburg. His understanding of Baroque polyphony and counterpoint enriched the developing Viennese Classicism of his own day.

Albret FAMILY, Gascon family celebrated in French history. The lords (sires) of Albret included warriors, cardinals, and kings of Navarre, reaching the height of their power in the 14th to 16th century. Their name derives from Labrit, a small village on the road from Bordeaux to Dax and Bayonne.

Members of the family fought in the First Crusade (1096–99), in the war against the Albigensian heretics in southern France (1209–29), and in the Hundred Years' War (1337–1453). In this conflict Arnaud-Amanieu d'Albret (d. 1401) changed to the French side and was richly rewarded (1368): King Charles V gave him not only his sister-in-law, Marguerite de Bourbon, but also lands and financial compensation. His son, Charles I d'Albret, constable of France, died at the Battle of Agincourt (1415).

Charles I's grandson, Alain, was known as Alain le Grand (1440–1522). The surname refers not to his deeds but to the vast domains over which he ruled as one of the last feudal lords. A daughter, Charlotte (1480–1514), was married to Cesare Borgia. Alain's son, Jean (d. 1516), became king of Navarre through his marriage with Catherine de Foix in 1484. In 1550 the lands of Albret were made a duchy. Jeanne d'Albret (1528–72), Jean's granddaughter, married Antoine de Bourbon and left her titles to her son, Henry III of Navarre, who became king of France as Henry IV. A member of the Miossans branch of the family, César-Phébus d'Albret (1614–76), was made marshal of France in 1654.

Albright, Ivan, in full IVAN LE LORRAINE ALBRIGHT (b. Feb. 20, 1897, North Harvey, Ill., U.S.—d. Nov. 18, 1983, Woodstock, Vt.), American painter noted for his meticulously detailed, exaggeratedly realistic depictions of decay and corruption.

Albright was educated at Northwestern Uni-

versity, Evanston, Ill., and the University of Illinois, Urbana, before World War I. After the war he trained at the School of the Art Institute of Chicago and, briefly, the Pennsylvania Academy of the Fine Arts and the National Academy of Design, New York City.

In 1927 Albright settled in Warrenville, Ill., near Chicago. Independently wealthy, he devoted himself to painting. In 1930 he completed "Into the World Came a Soul Called Ida," a portrait of an aging, flabby woman looking into a mirror. Ultracalistic, it conveyed the ravages of time with startling surface detail. His first one-man show was held in Chicago the same year.

In 1931 Albright began "That Which I Should Have Done I Did Not Do," showing a scarred, decrepit door on which is hung a funeral wreath. It was completed in 1941 and is considered to be one of his masterpieces. His portrait (1943–44) of the final stage in the disolute life of the title character in *The Picture of Dorian Gray* brought him fame. Among his other works are "God Created Man In His Own Image" (1929–30) and "Portrait of Mary Block" (1955–56). The pale, unearthly light and hallucinatory proliferation of detail in Albright's paintings convey an atmosphere of age and decay with morbid emotional intensity.

Albright, Madeleine, *née* MARIE JANA KORBEL (b. May 15, 1937, Prague, Czech.), American public official, former ambassador to the United Nations, and the first woman to hold the cabinet post of U.S. secretary of state.

Marie Jana Korbel was the daughter of a Czech diplomat. After the Nazis occupied Czechoslovakia in 1939, her family fled to England. Although she spent most of her life believing that they had fled for political reasons, she learned in 1997 that her family was Jewish and that three of her grandparents had died in German concentration camps. The family returned to Czechoslovakia after World War II, but the Soviet-sponsored communist coup made them refugees again, and by 1948 they had settled in the United States.

Korbel graduated from Wellesley (Massachusetts) College (B.A., 1959) and married Joseph Albright, a member of the Medill newspaper-publishing family. After earning (1968) a master's degree from Columbia University, New York City, she worked for Senator Edmund Muskie's failed 1972 presidential campaign and later as Muskie's chief legislative assistant. By 1976 she had received a Ph.D. from Columbia and was working for the Carter administration on national security issues.

During the 1980s and early '90s, Albright worked for several nonprofit organizations, and her Washington, D.C., home became a salon for influential Democratic politicians and policy makers. She also was professor of international affairs at Georgetown University, Washington, D.C., from 1982 to 1993. She was ambassador to the United Nations in 1993. There she gained a reputation for tough-mindedness, and she was a fierce advocate for American interests. She promoted an increased role for the United States in UN operations, particularly those with a military component. Her nomination to the position of secretary of state was unanimously confirmed by the Senate in 1997.

Albright, Tenley, in full TENLEY EMMA ALBRIGHT (b. July 18, 1935, Newton Centre, Mass., U.S.), first American woman to win the world amateur figure-skating championship (1953) and an Olympic Games gold medal in figure skating (1956). She was also the first to win the world, North American, and United States titles in a single year (1953).

Albright began to skate seriously at the age of 11 in order to regain her strength following an

attack of nonparalytic poliomyelitis. She won five straight U.S. senior women's championships (1952 through 1956) and two consecutive North American titles (1953 and 1955). In 1953 she won her first world championship and in 1955 won again. In the 1952 Olympic Winter Games she won a silver (second-place) medal, and in 1956 she won the Olympic women's figure-skating competition.

Educated at Radcliffe College and Harvard University (M.D., 1961), Albright in 1961 married Tudor Gardiner, an investment broker, and entered medical practice in Boston.

Albright, W.F., in full WILLIAM FOXWELL ALBRIGHT (b. May 24, 1891, Coquimbo, Chile—d. Sept. 19, 1971, Baltimore, Md., U.S.), American biblical archaeologist and Middle Eastern scholar, noted especially for his excavations of biblical sites.

The son of American Methodist missionaries living abroad, Albright came with his family to the United States in 1903. He obtained his doctorate in Semitic languages at Johns Hopkins University. While there he studied under Paul Haupt, whom he succeeded in 1929 as W.W. Spence professor of Semitic languages, a position he held until his retirement in 1958.

Appointed fellow of the American School of Oriental Research, Jerusalem, in 1919, Albright served as the school's director for 12 years (1920–29, 1933–36). Among his excavations were Gibeah of Saul, Tell Beit Mirsim (Kirjath-Sepher), and, in association with others, Beth-zur and Bethel in Palestine and Baluah, and Petra in Jordan. In 1950–51 he was chief archaeologist of excavations made by the American Foundation for the Study of Man at Wadi Bayhan (Beihan), Hajar Bin Humaid, and Timna in Arabia.

Albright's scientific writings greatly influenced the development of biblical and related Middle Eastern scholarship and include *The Archaeology of Palestine and the Bible* (1932–35), *Archaeology and the Religion of Israel* (1942–46), and *The Bible and the Ancient Near East* (1961).

Albright-Knox Art Gallery, museum in Buffalo, N.Y., that is noted for its collections of contemporary painting and sculpture, including American and European art of the 1950s, '60s, and '70s.

Founded in 1862 as the Buffalo Fine Arts Academy, the Albright Art Gallery began to operate in its own building in 1905. In 1962 the gallery opened a major addition, designed by Gordon Bunshaft and donated by the Seymour H. Knox Foundation, and took the name Albright-Knox Art Gallery.

Albucasis (physician): *see* Abū al-Qāsim.

Albumazar, also spelled ALBUMASAR, or ABŪ MA'SHAR (b. Aug. 10, 787, Balkh, Khorāsān [now in Afghanistan]—d. March 9, 886, al-Wāsit, Iraq), leading astrologer of the Muslim world, who is known primarily for his theory that the world, created when the seven planets were in conjunction in the first degree of Aries, will come to an end at a like conjunction in the last degree of Pisces.

Albumazar's reputation as an astrologer was immense, both among his contemporaries and in later times. He was the archetype of the knavish astrologer in the play *Lo astrologo* (1606) by the Italian philosopher and scientist Giambattista della Porta. This play was the basis for *Albumazar* by Thomas Tomkis, which was revived by the English poet John Dryden in 1668. Albumazar's principal works include *Kitāb al-Madkhal al-Kabīr 'alā 'ilm aḥkām al-nujūm* ("Great Introduction to the Science of Astrology"), *Kitāb al-qirānāt* ("Book of Conjunctions"), and *Kitāb taḥwīl sinī al-'ālam* ("Book of Revolutions of the World-Years").

albumen paper, albumen also spelled ALBUMIN, light-sensitive paper prepared by coating

with albumen, or egg white, and a salt (e.g., ammonium chloride) and sensitized by an after-treatment with a solution of silver nitrate. The process was introduced by the French photographer Louis-Désiré Blanquart-Evrard in about 1850 and was widely used for about 60 years thereafter. Early employers of the process applied by hand the albumen and the silver solution, but by 1869, paper thus treated could be stored and marketed in bulk.

Albumen was also used during this period as a binder for the light-sensitive crystals on glass-plate negatives. Albumen prints are prized by modern collectors for their subtly graded tones and fine-grained resolution.

albumin, a type of protein that is soluble in water and in water half saturated with a salt such as ammonium sulfate. Serum albumin is a component of blood serum; α -lactalbumin is found in milk. Ovalbumin constitutes about 50 percent of the proteins of egg white; conalbumin is also a component. Seeds contain very small amounts of albumins (0.1–0.5 percent by weight). *See also* proteinuria.

The term albumen was once applied to water-soluble protein systems, such as egg white, containing proteins other than albumins.

albuminuria (medicine): *see* proteinuria.

Albuquerque, largest city of New Mexico, U.S., seat (1852) of Bernalillo county, on the Rio Grande opposite a pass between the Sandia and Manzano mountains to the east. It is encircled by Indian pueblos and sections of the Cibola National Forest (of which it is headquarters). Founded in 1706 by Don Francisco Cuervo y Valdés, governor and captain general of New Mexico, it was named for

The mission church of San Felipe de Neri, Albuquerque, N.M.

W. Hearne—Shostal/EB Inc

the Duque de Alburquerque, then viceroy of New Spain (the first *r* was later dropped). It became an important trading centre on the Chihuahua Trail from Mexico.

After 1800 growing commerce on the Santa Fe Trail brought an influx of settlers; an army post was established there following U.S. occupation in 1846. During the Civil War the town was captured by the Confederates (1862) but remained loyal to the Union. The original plaza was the town centre until 1880, when the Atchison, Topeka and Santa Fe Railway laid its tracks 1 mi east. The two places were joined by a streetcar line and the settlement grew as a wool centre and food-processing point. The characteristically Spanish "old town" and the mission Church of San Felipe de Neri (1706) have survived.

Since the 1930s more than 100 federal agencies have been established there, and the development of nuclear, aerospace, and solar research industries after World War II (especially at the Sandia Laboratories and Sandia Base, Kirtland Air Force Base [adjacent to the International Airport], and the Defense Atomic Support Agency) caused a large population influx. Manufactures include truck trailers, gypsum products, lumber, clothing, and aerospace components. At an altitude of 5,314

ft (1,620 m) and with a dry, warm climate, Albuquerque became known as a health centre for the treatment of tuberculosis. Tourism is an important adjunct to the economy, and the city is a service centre for ranching, mining, and timber operations. The Sandia Peak Ski Area, with an aerial tramway, is a few miles northeast. The New Mexico State Fair is held annually (in mid-September). The Santa Fe maintains large railroad shops in the city.

The University of New Mexico was founded there in 1889, the University of Albuquerque in 1920, and Albuquerque Academy in 1955. The city is also the site of the Albuquerque Technical-Vocational Institute. Inc. 1890. Pop. (1990) city, 384,736; Albuquerque MSA, 480,577.

Albuquerque, Afonso de, THE GREAT (b. 1453, Alhandra, near Lisbon—d. Dec. 15, 1515, at sea, off Goa, India), Portuguese soldier, conqueror of Goa (1510) in India and of Melaka (1511) on the Malay Peninsula. His program to gain control of all the main maritime trade routes of the East and to build permanent fortresses with settled populations laid the foundations of Portuguese hegemony in the Orient.

Albuquerque was the second son of the senhor of Vila Verde. His paternal great-grandfather and grandfather had been confidential secretaries to kings John I and Edward (Duarte); his maternal grandfather had been admiral of Portugal. Albuquerque served 10 years in North Africa, where he gained early military experience crusading against Muslims. He was present at Afonso V's conquest of Arzila and Tangier in 1471. King John II (ruled 1481–95) made him master of the horse, a post Albuquerque held throughout the reign. In 1489 he again served in North Africa at the defense of Graciosa. Under John's successor, Manuel I, Albuquerque was less prominent at court but again served in Morocco.

Although Albuquerque made his mark under the stern John II and gained his experience in Africa, his reputation rests on his service in the East. When Vasco da Gama returned to Portugal in 1499 from his pioneering voyage around the Cape of Good Hope to India, King Manuel straightway sent a second fleet under Pedro Álvares Cabral to open relations and trade with the Indian rulers. The Muslim traders who had monopolized the distribution of spices turned the zamorin, or Hindu prince of Calicut, against the Portuguese. His dependency, Cochin, on the southwestern Indian coast, however, welcomed them. In 1503 Albuquerque arrived with his cousin Francisco to protect the ruler of Cochin, where he built the first Portuguese fortress in Asia and placed a garrison. After setting up a trading post at Quilon, he returned to Lisbon in July 1504, where he was well received by Manuel and participated in the formulation of policy. In 1505 Manuel appointed Dom Francisco de Almeida first governor in India, with the rank of viceroy. Almeida's object was to develop trade and aid the allies of the Portuguese. Albuquerque left Lisbon with Tristão da Cunha in April 1506 to explore the east coast of Africa and build a fortress on the island of Socotra to block the mouth of the Red Sea and cut off Arab trade with India. This done (August 1507), Albuquerque captured Hormuz (Ormuz), an island in the channel between the Persian Gulf and the Gulf of Oman, to open Persian trade with Europe. His project of building a fortress at Hormuz had to be abandoned because of differences with his captains, who departed for India. Albuquerque, though left with only two ships, continued to raid the Persian and Arabian coasts.

King Manuel appointed Albuquerque to succeed Almeida at the end of his term, though without the rank of viceroy. When Albuquerque reached India in December 1508, Almeida had crushed the improvised sea force of Cali-

cut, but a navy from Egypt had defeated and killed his son. Insisting on retaining power until he had avenged his son's death, Almeida, to avoid interference, had Albuquerque imprisoned. Almeida defeated the Muslims off Diu in February 1509, and it was only in the following November, with the arrival of a fleet from Portugal, that he finally turned his office over to Albuquerque.

Albuquerque's plan was to assume active control over all the main maritime trade routes of the East and to establish permanent fortresses with settled populations. His attempt to seize Cochin in January 1510 was unsuccessful. By February Albuquerque had realized that it was better to try to supplant the Muslims; assisted by a powerful corsair named Timoja, he took 23 ships to attack Goa, long ruled by Muslim princes. He occupied it in March 1510, was forced out of the citadel by a Muslim army in May, and was finally able to carry it by assault in November. The Muslim defenders were put to the sword.

After this victory over the Muslims, the Hindu rulers accepted the Portuguese presence in India. Albuquerque planned to use Goa as a naval base against the Muslims, to divert the spice trade to it, and to use it to supply Persian horses to the Hindu princes. By marrying his men to the widows of his victims he would give Goa its own population, and its supplies would be assured by the village communities under a special regime. After providing for the government of Goa, Albuquerque embarked on the conquest of Malacca, on the Malay Peninsula, the immediate point of distribution for the Spice Islands and points east. He took that port in July 1511, garrisoned it, and sent ships in search of spices.

In the meantime Goa was again under heavy attack. He left in January 1512 and relieved Goa. Having established himself there and having gained control over the movement of goods by a licensing system, Albuquerque again turned to the Red Sea, taking a force of Portuguese and Indians. Because Socotra was inadequate as a base, he attempted to take Aden, but his forces proved insufficient. He thereupon explored the Arabian and Abyssinian coasts. Returning to India, he finally subdued Calicut, hitherto the main seat of opposition to the Portuguese.

In February 1515 he again left Goa with 26 ships for Hormuz, gaining control of part of the island. He was taken ill in September and turned back to Goa. On the way he learned that he had been superseded by his personal enemy, Lope Soares; he died embittered on shipboard before reaching his destination.

Albuquerque's plans derived from the crusading spirit of John II and others. He did not allow himself to be diverted from his schemes by considerations of mercantile gain. His boldest concepts, such as turning the Persians against the Turks or ruining Egypt by diverting the course of the Nile, were perhaps superhuman, but so perhaps was his achievement. (H.V.L.)

BIBLIOGRAPHY. Biographies of Albuquerque in English are: H. Morse Stephens, *Albuquerque*, in "Rulers of India Series" (1892); E. Prestage, *Afonso de Albuquerque, Governor of India* (1929), a brief, scholarly account; and E. Sanceau, *Indies Adventure* (1938). Albuquerque's remarkable series of reports and letters have been published by the Lisbon Academy of Sciences, *Cartas*, 7 vol. (1884–1935). They were drawn on by his son Brás (later called Afonso) de Albuquerque for the *Commentarios de Afonso Dalboquerque*, completed in 1557, revised in 1576, and reported in 1774. The Hakluyt Society published an English translation by W. de G. Birch, *The Commentaries of the Great Afonso Dalboquerque*, 4 vol. (1875–84; reprinted 1970).

albumnum (botany): *see* sapwood.

Albury-Wodonga, urban centre comprising twin cities on opposite sides of the Murray River and the New South Wales-Victoria border, Australia. By rail the region is about 398 mi (640 km) southwest of Sydney and nearly 186 mi northeast of Melbourne. In 1973 the Commonwealth and the two state governments agreed to plan and develop the growing cities through the Albury-Wodonga Development Corporation. The area is a focus for agricultural, pastoral, and dairying industries. An important wholesale distributing centre and the largest stock and rail-trucking centre on the Sydney-Melbourne rail line, Albury-Wodonga also has steel plants, automotive and electrical parts factories, concrete and fertilizer works, printing plants, textile mills, and sawmills. Hume Reservoir is used for water sports and irrigation. Pop. (1996) 70,983.

Alburz Mountains (Iran): *see* Elburz Mountains.

Alcaeus (b. c. 620 BC, Mytilene, Lesbos—d. c. 580 BC), Greek lyric poet. His work was highly esteemed in the ancient world. A collection of Alcaeus' surviving poems in 10 books (now lost) was made in the 2nd century BC, and he was a favourite model of the Roman lyric poet Horace, who adapted from him his own alcaic stanza.

Only fragments and quotations from Alcaeus' work survive, but they are enough to show the extent of his themes and to reveal his quality as a poet.

His poems may be classed in four groups: hymns in honour of gods and heroes, love poetry, drinking songs, and political poems. Many of the fragments reflect the vigour of the poet's involvement in the life of Mytilene, particularly its political life.

After years of political unrest, some measure of stability had come to Mytilene through the acquisition of power by Pittacus. He had a reputation for mildness and was rated one of the Seven Sages of Greece. Alcaeus fought beside Pittacus against the Athenians, but Pittacus betrayed Alcaeus, whose respect turned into hatred. Several fragments testify to the bitterness of his attack. He derides Pittacus for his splayfeet, his fat belly, his stinginess, and his intemperance. The most serious of the charges brought by this immoderate conservative is made against Pittacus' origin: "They have set up the low-born Pittacus as a tyrant over our gutless and godforsaken city."

Other fragments of Alcaeus' work convey the atmosphere of everyday life in 6th-century Mytilene. He writes of ships and rivers, of wine and banquets, of a girls' beauty contest, of a flock of widgeon in flight, and of the flowers that herald the spring. He managed to convey what can well be believed to have been the spirit and the values of the city-states of the Aegean, as, for example, when he declares where real greatness lies: "Not in well-fashioned houses, nor in walls, canals, and dockyards, but in men who use whatever Fortune sends them."

alcaic, classical Greek poetic stanza composed of four lines of varied metrical feet, with five long syllables in the first two lines, four in the third and fourth lines, and an unaccented syllable at the beginning of the first three lines (anacrusis). The Greek alcaic stanza is scanned:

|c |—u |—u |—u |—u |—
 |c |—u |—u |—u |—u |—
 |c |—u |—u |—u |—u |—
 —u |—u |—u |—u |—u |—

Named for and perhaps invented by Alcaeus, a poet of the late 7th and early 6th centuries BC, the alcaic became an important Latin

verse form, especially in the *Odes* of Horace. Variations on the traditional alcaic include the use of a long initial syllable and of a spondee (—) in the first complete foot of the first three lines. Alcaics were adapted to English and French verse during the Renaissance and later appeared in works such as Tennyson's "Milton."

Alcalá, Calle de, one of the main thoroughfares of Madrid. It originates at the eastern edge of the Puerta del Sol (the focal point and principal square of the city) and runs northeast approximately 4 mi (6 km) through the Plaza de la Independencia and the Puerta de

The Puerta de Alcalá on Calle de Alcalá, Madrid
Archivo Mas, Barcelona

Alcalá (a gateway originally built in 1599 and rebuilt in 1778). A broad, tree-lined avenue, it contains government offices and banks and is the location of the Real Academia de Bellas Artes de San Fernando (an academy of art and music, founded in 1752). Along the western end of the avenue and especially around the Puerto del Sol are many shops and department stores.

Alcalá de Guadaira, town, Sevilla province, in the autonomous community (region) of Andalusia, southwestern Spain, on the Río Guadaira, just southeast of Seville city. The town is popularly known as Alcalá de los Panaderos (Alcalá of the Bakers) because of its large number of bakeries and flour mills that supply Sevilla with most of its flour. Olives are also exported, and oil is pressed and refined in the town. Tourism, based on the healthful climate of the area, is of growing economic importance. The nearby remains of a Moorish castle, captured by Christian forces in 1246, were declared a national monument in 1925. Pop. (1998 est.) 56,244.

Alcalá de Henares, city, Madrid province, central Spain. Known under the Romans as Complutum, the city was destroyed in 1000 and rebuilt in 1038 by the Moors, who called it al-Qal'ah an-Nahr. It was reconquered in 1088 by Alfonso VI and granted with the surrounding lands to the archbishop of Toledo. The city contains the unique Gothic church of San Justo (built 1136 and called La Magistral), which was badly damaged during the Civil War (1936–39) but later restored, and the former archbishop's palace, now a seminary that houses the General Central Archives of Spain, containing documents of the Inquisitions of Toledo and Valencia. The original University of Alcalá de Henares, founded about the beginning of the 16th century, was moved to Madrid in 1836 and renamed the Complutensian University of Madrid. A new University of Alcalá de Henares was founded in 1977. There is also a university for technical and specialized workers (inaugurated in 1966) and a school of philosophy for Jesuits. The city has an airfield and is the site of military quarters.

Manufactures include chemicals, cotton goods, perfumes, pottery, electrical and domestic appliances, and the famous (iced) almonds of Alcalá. Alcalá de Henares was the birthplace of the author Miguel de Cervantes (who in his great novel *Don Quixote* referred to the city as the Great Complute), the em-

peror Ferdinand I, and Catherine of Aragon (first wife of the English king Henry VIII). Pop. (1998 est.) 163,831.

Alcalá de Henares, University of: *see* Madrid, Complutensian University of.

Alcalá Zamora, Niceto (b. July 6, 1877, Priego, Spain—d. Feb. 18, 1949, Buenos Aires), Spanish statesman, prime minister, and president of the Second Republic (1931–36), whose attempts to moderate the policies of the various factions led eventually to his deposition and exile.

Elected to the Cortes (parliament) in 1905, Alcalá Zamora became minister of works in 1917 and minister of war in 1922. The Spanish defeat at Anual in Morocco led to an enquiry, as a result of which Gen. Primo de Rivera seized power, dissolved parliament, suppressed the report, and concluded the war. Alcalá Zamora blamed King Alfonso XIII for the dictatorship and became a republican, joining the socialists and Catalan left in the Pact of San Sebastián (August 1930). As leader of the revolutionary committee, he successfully demanded Alfonso's abdication on the basis of the municipal elections of April 1931. Alfonso left Spain, and Alcalá Zamora went from prison to become prime minister. He resigned on Oct. 14, 1931, however, when the Cortes included strongly anticlerical articles in the new constitution. Nevertheless, on December 11 he was elected the first president of the Second Republic.

Although as a Catholic he disagreed with the new constitution, he attempted to use his limited powers to moderate the increasing polarization of parties, curbing the extremists on the left in 1934 and refusing to allow constitutional revisionists to take power. As a result he was attacked by almost all parties; and, after the election of the Popular Front in February 1936, the Cortes voted by 238 to 5 to depose him on a technicality. He went to France and then to Argentina, dying in exile.

alcalde (from Arabic *al-qāḍī*, "judge"), the administrative and judicial head of a town or village in Spain or in areas under Spanish control or influence. The title was applied to local government officials whose functions were various but always included a judicial element. Types of alcaldes were differentiated according to the specialized nature of their judicial functions: the *alcalde de corte* was a judge of the palace court with jurisdiction in and about the residence of the king; the *alcalde mayor* assisted the royally appointed judges (*corregidores*) in the towns. *Alcaldes de crimen* were the ordinary judges in criminal cases in Spanish *audiencias* (courts). From the 19th century the alcalde had the dual character of leader of the local council (*ayuntamiento*) and representative of the central government. His duties became mainly administrative with scarcely any judicial functions. *Alcaldes de hermandad* were minor municipal officials with police and judicial powers.

In the Spanish colonies in the Americas, *alcaldes ordinarios* (magistrates) held seats on *cabildos* (town councils) along with *regidores* (councillors). *Alcaldes mayores* were minor officials sent to small Indian communities (as *corregidores de indios* were sent to larger ones) with practically complete civil and judicial jurisdiction over them; they were usually unsalaried. *Alcaldes de hermandad* (sometimes termed *alcaldes de la Mesta*) were rural police officials. From 1635 in Peru, and probably simultaneously in New Spain, the office of *alcalde provincial* was instituted, which closely paralleled that of the *alcalde de hermandad*. *Alcaldes de indios* were minor officials in the civil *reducciones* (Indian settlements) who answered to the *cacique* (local Indian chief) and the Spanish *corregidor* of the district. *Alcaldes de barrio* were in charge of districts in the larger cities. *Corregidores* and *alcaldes mayo-*

res, often corrupt and rapacious toward their wards, were displaced by 1790 in all of Spanish America by new officials called *intendentes* in Charles III's reform, following a similar policy initiated earlier in Spain and implemented by José de Gálvez, his minister of colonies.

Alcámenes (fl. late 5th century BC, Lemnos, in the Aegean Sea, and Athens [Greece]), sculptor and younger contemporary of Phidias, noted for the delicacy and finish of his works, among which a Hephaestus and an "Aphrodite of the Gardens" are noteworthy. A copy of the head of his "Hermes Propylaeus" at Pergamum has been identified by an inscription, and he is said by the Greek traveler Pausanias (2nd century AD) to have been the creator of one of the pediments of the Temple of Zeus at Olympia.

Alcamo, town, Trapani *provincia*, northwestern Sicily, Italy, 23 miles (37 km) west-southwest of Palermo. The name comes from that of the nearby Saracen fortress, Alqamah, on Mount Bonifato. The present town was founded by the emperor Frederick II in 1233. Notable churches include the 17th-century Assunta Church and the Church of San Tomaso with an elaborate 14th-century doorway. Alcamo is an agricultural and industrial centre. Pop. (1999 est.) mun., 43,553.

Alcan Aluminium Limited, Canadian multinational company incorporated in 1928 (as Aluminium Limited) and now the largest Canadian industrial enterprise, operating in more than 100 countries. It has mining and refining operations for bauxite; smelting plants for aluminum; hydroelectric plants; fabricating plants for a wide variety of aluminum products; transportation operations; facilities for production and sale of industrial chemicals; and research and development laboratories. Head offices are in Montreal. The current name was adopted in 1966.

The company's history traces to 1902, when the Northern Aluminum Company was incorporated as a Canadian subsidiary of the Aluminum Company of America (Alcoa). In 1925 the name was changed to Aluminium Company of Canada, Ltd., resulting in the Alcan trademark. In 1928 it was renamed Aluminium, reincorporated, and separated from its parent company, Alcoa, which transferred to it almost all of Alcoa's assets then held outside the United States. In return, Alcoa's stockholders received the common stock of Aluminium Limited. Major stockholders of the two companies continued to be identical until 1951, when a U.S. District Court compelled them to sell their stock in one or the other company in order to remove the appearance of collusive action. Most of the current shareholders of Alcan are Canadians. Once a major producer of raw materials, the company is now a major supplier of fabricated products.

Alcan Highway: see Alaska Highway.

Alcántara, town, Cáceres *provincia*, in the Extremadura *comunidad autónoma* ("autonomous community"), western Spain, on a rock above the southern bank of the Tagus (Tajo) River just east of the Portuguese frontier. The walled town was named by the Moors after the six-arched Roman bridge Al-Qanṭarah (Arabic: "The Bridge"), which there spans the Tagus. Built in AD 105–106 in honour of the emperor Trajan, the bridge, 670 feet (204 m) long, was destroyed by the Moors in 1214 but was restored in 1543 and many times since. It has been called "one of the noblest Roman monuments in Spain." In 1218 Alcántara was given to an order of knights who, upon being given the town by Alfonso IX, took its name for their order. In addition to the bridge, notable landmarks include the church of Santa María de Almocóbar, dating from the 13th century, and that of San Benito

(1576), which belonged to the convent (now ruined). Pop. (1996 est.) mun., 1,876.

Alcántara, Order of, Christian military order in Spain founded in 1156 by Don Suero Fernández Barrientos and recognized in December 1177 by Pope Alexander III in a special papal bull. Its purpose was to defend Christian Spain against the Moors. In 1218 King Alfonso IX of Leon gave to the order the town of Alcántara, and during the next two centuries its knights defended the southern borders of Christian Spain. Membership reached 100,000, and the order's annual income was between 40,000 and 50,000 ducats. After Ferdinand II of Aragon and Isabella I of Castile incorporated the military orders into the crown in 1493, the fiefs of the Order of Alcántara formed part of the royal heritage.

Alcântara, Osvaldo: see Lopes da Silva, Baltasar.

Alcaraz carpet, floor covering handwoven in 15th- and 16th-century Spain at Alcaraz in Murcia. These carpets use the Spanish knot on one warp. A number of 15th-century examples imitate contemporary Turkish types but differ in border details and colouring.

There are several different patterns of carpet with "wheels" in rectangular compartments. Other carpets imitate a wide range of brocade and velvet patterns. A remarkable number of these carpets survive, either complete or as fragments. The colouring is vivid, with a good, apparently madder, red in the 15th-century examples; but, in the 16th century, reds seem suddenly to lighten into coral and salmon shades and then disappear, perhaps owing to difficulties in setting the cochineal dye that was being imported in quantity from Mexico. A fashion then arose for carpets in two shades of green, yellow, or black-brown and white. Brocade and velvet patterns continued in use, especially an ogee lattice with crowns at points of intersection. The favourite design, however, was of wreaths of serrated leaves in rows, perhaps a continuation in spirit of the wheel design of the 15th century. The border now generally had a broad stripe, sometimes of arabesque dragons, and the narrow guard stripes might show the knotted cord of the Franciscan order. Alcaraz carpets closely resemble contemporary rugs from Salamanca and Valencia.

Alcatraz Island, byname THE ROCK, rocky island in San Francisco Bay, California, U.S., occupying an area of 22 acres (9 hectares) 1.5 miles (2 km) offshore.

The island had little vegetation and was a seabird habitat when it was explored in 1775 by Lieutenant Juan Manuel de Ayala, who named it Isla de los Alcatrazes ("Isle of the Pelicans"). Sold in 1849 to the U.S. government, Alcatraz has the distinction of being the site of the first lighthouse (1854) on the coast of California. Thereafter other buildings were erected on the island, and the first army detachment was garrisoned there in 1859. In 1868 the island was designated as a residence for military offenders. Later prisoners included rebellious Indian scouts from the Arizona territory, American soldiers fighting in the Philippines who had deserted and joined the Filipino cause in 1900, and civilians who had resisted the U.S. army in China. In 1907 the island was designated the Pacific Branch of the United States Military Prison. From 1934 to 1963 it served as a federal prison for the most dangerous civilian prisoners. Among its famous denizens were Al Capone, George "Machine Gun" Kelly, and Robert Stroud, the "Birdman of Alcatraz." Though the Alcatraz penitentiary was able to house 450 convicts in cells that measured about 10 by 4.5 feet (3 by 1.5 m), never more than 250 prisoners occupied the island at one time. Escape attempts were rare, but a few inmates did escape from the island; whether they survived the currents

of the bay is unknown. Eventually the necessity of transporting fresh water to and waste away from the island resulted in the island's abandonment in 1963.

In March 1964 a group of Sioux Indians claimed the island, citing an 1868 treaty with the Sioux allowing Indians from the reservation to claim any "unoccupied government land." In November 1969 a group of eighty-nine Indians occupied the island, remaining there until they were forced off by federal marshals in June 1971.

Alcatraz Island, seen from Hyde Street in San Francisco

Tim Thompson

In 1972 Alcatraz became part of the newly created Golden Gate National Recreation Area. Although no effort has been made to repair the structures on the island—most suffered general decay and weathering, and the historic lighthouse and four other buildings burned in 1970—Alcatraz Island is now open to the public.

alcázar, any of a class of fortified structures built in the 14th and 15th centuries in Spain. (The term is derived from the Arabic word *al-qasr*, meaning "castle," or "fortress.") As the Spanish efforts to drive out the Moors became more strenuous, the dual need for fortification and an imposing edifice became increasingly apparent. In form, an *alcázar* is generally rectangular with easily defensible walls and massive corner towers.

Inside the *alcázar* was a large open space (patio) surrounded by chapels, salons, hospitals, and sometimes gardens. *Alcázares* were built at Segovia (14th century) and at Toledo (14th

Toledo *alcázar*, 14th century, renovated 16th century, severely damaged during the Spanish Civil War and later restored

Alfonso Gutierrez—Escera

century, renovated 16th century), but the best known is the *alcázar* at Seville; its walls were erected in 1364.

Alcázar de San Juan, town, Ciudad Real *provincia*, in the *comunidad autónoma* ("autonomous community") of Castile-La Mancha, central Spain. It lies on the high Meseta Central at 2,135 feet (650 m) above sea level. Known to the Romans as Alces, the town was renamed al-Qasr ("the Palace," or "the Castle") by the Arabs. It was conquered by the Knights of St. John (Spanish: San Juan) of Jerusalem (the Hospitalers) in 1186 and captured from them by King Sancho IV of Castile in 1292; the town was the centre of the Order of Saint John in the 14th, 15th, and 16th centuries. Historic landmarks include the 14th-century tower of Don Juan of Austria, the Santa María Church on the site of a pre-Christian temple of Hercules, and the municipal archaeological museum, containing Roman mosaics from the 2nd and 3rd centuries. The town processes wheat, olives, wines, and cheeses, especially a cheese made from sheep's milk. Industry includes soap factories, railway works, and ironworks. Pop. (1991 prelim.) 25,972.

Alcedinidae (bird family): *see* kingfisher.

alchemy, pseudoscience whose aims were to transform base metals such as lead or copper into silver or gold. Although such attempts have involved chemical procedures, evidence linking alchemy with the development of chemistry itself remains inconclusive.

A brief treatment of alchemy follows. For full treatment, *see* MACROPAEDIA: Occultism.

The theory that five elements (air, water, earth, fire, space) in various combinations constitute all matter was postulated in almost identical form in ancient China, India, and Greece. Further, the world of matter was seen to function by means of antagonistic, opposing "forces"—*e.g.*, hot and cold, wet and dry, positive and negative, male and female. Under their similar astrological heritages, philosophers of these three cultures found correspondences among the elements, planets, and metals.

Astrologers believed that events in the macrocosm of the natural world were reflected in the human microcosm, and vice versa. Thus, under the proper astrological influences, a "perfection," or "healing," of lead into gold might occur, just as the human soul could achieve a perfect state in heaven. The artisan in his laboratory could perhaps hasten this process by careful nurture and long heating, by "killing" the metal and then "reviving" it in a finer form.

While the practical alchemists invented and used many laboratory apparatuses and procedures that in modified form are used today, they were still essentially artisans and did not wish to reveal their trade secrets. In an effort to preserve the esoteric nature of their practices, they devised many concealing, symbolic names for the materials with which they worked.

These confusing tendencies were intensified as the mystically minded began to develop alchemical ideas. As Hellenistic philosophy shifted more and more from the technical scientific viewpoint to the emphasis on divine revelation of Gnosticism, Neoplatonism, and Christianity, the alchemical writings became esoteric to the point of total obscurity. In time the Chinese practitioners, who sought to make gold not for its own sake but as an elixir of immortality, also came to emphasize the esoteric aspects at the expense of all practical technique, and the art degenerated into a mass of superstition. Alchemy in India eventually met with a similar fate.

Arabic alchemy is as mysterious in its origins as the other currents. It presumably migrated during the Hellenistic period to Egypt, where it became incorporated into the work of the first alchemist whose identity has been authenticated, Zosimos of Panopolis. Through their contact with China, the Arabs adopted the use of a transmuting "medicine," the mysterious substance that appears later in European alchemy as the philosopher's stone. Translations of the Arabic works of ar-Rāzi (*c.* 850–923/924) by Christian scholars in the 12th century led to a revival of alchemy in Europe. By 1300 the subject was being discussed by the leading philosophers, scientists, and theologians of the day. Important alchemical discoveries of the period include the mineral acids and alcohol. Medical chemistry, or pharmacy, emerged from this revival two centuries later under the influence of Paracelsus (1493–1541), a Swiss-German alchemist.

Renaissance physicists and chemists began to discount the possibility of transmutation on the basis of a renewed interest in Greek atomism. The chemical facts that had been accumulated by the alchemists were now reinterpreted and made the basis upon which modern chemistry was erected. It was not until the 19th century, however, that the possibility of chemical gold-making was conclusively contradicted by scientific evidence. Sporadic revivals of alchemical philosophies and techniques persisted into the 20th century.

Alchevsk, formerly (1931–61) VOROSHILOVSK, or (1961–92) KOMMUNARSK, city, Luhansk *oblast* (province), eastern Ukraine. It lies along the railway from Luhansk to Debaltsevo. Alchevsk was founded in 1895 with the establishment of the Donetsko-Yuryevsky ironworks. The plant has developed into a large, integrated ironworks and steelworks, which was expanded greatly in the 1950s and '60s. The city is a major bituminous-coal mining centre, and there are coke-chemical and metalworking industries. Alchevsk presents an undistinguished appearance of modern apartment blocks, industrial enterprises, and old one-story houses. It has a mining and metallurgical institute. Pop. (1991 est.) 126,000.

Alcibiades (b. *c.* 450 BC, Athens [Greece]—d. 404, Phrygia [now in Turkey]), brilliant but unscrupulous Athenian politician and military commander who provoked the sharp political antagonisms at Athens that were the main causes of Athens' defeat by Sparta in the Peloponnesian War (431–404 BC).

Alcibiades, Roman copy of a Greek sculpture of about the second quarter of the 4th century BC; in the Chiaramonti Museum, Rome

By courtesy of the Direzione Generale dei Monumenti, Musei e Gallerie Pontificie

Well-born and wealthy, Alcibiades was only a small boy when his father—who was in command of the Athenian army—was killed in 447 or 446 BC, at Coronea, Boeotia. Alcibiades' guardian, the statesman Pericles, a distant relation, was too preoccupied with political leadership to provide the guidance and affection that the boy needed. As he grew

up, Alcibiades was strikingly handsome and keen witted, but he was extravagant, irresponsible, and self-centred as well. He was, however, impressed by the moral strength and the keen mind of the philosopher Socrates, who, in turn, was strongly attracted by Alcibiades' beauty and intellectual promise. They served together at Potidaea (432) in the Chalcidice region, where Alcibiades was defended by Socrates when he was wounded, a debt that he repaid when he stayed to protect Socrates in the flight from the Battle of Delium (424), north of Athens. Yet before he was 30 he had abandoned the intellectual integrity that Socrates demanded, in favour of the rewards of the kind of politics that Socrates despised.

During the 420s Alcibiades was best known for his personal extravagance and his courage in battle; but he had also become a recognized speaker in the Ecclesia (assembly), and as Athens moved toward peace, he hoped that the ties that had once existed between his family and Sparta would enable him to secure the credit for bringing peace to Athens. According to the historian Thucydides, who knew Alcibiades well and judged him dispassionately, it was the fact that the Spartans instead chose to negotiate through established political leaders that dictated Alcibiades' subsequent choice of policies.

General for the first time in 420, he opposed the aristocratic leader Nicias, who had negotiated peace, and steered Athens into an anti-Spartan alliance with Argos, Elis, and Mantinea, three city-states of the Peloponnese. This alliance was defeated by Sparta at the Battle of Mantinea (418). Alcibiades, however, escaped ostracism, a form of banishment, by joining forces with Nicias against Hyperbolus, the successor of the demagogue politician Cleon as champion of the common people. In 416 Alcibiades restored his reputation by entering seven chariots at Olympia and taking first, second, and fourth places. This made it easier for him, in 415, to persuade the Athenians to send a major military expedition to Sicily against the city of Syracuse. He was appointed to share the command, but, shortly before the expedition was due to sail, the hermae (busts of Hermes, messenger of Zeus and patron of all who use the roads, set up in public places throughout the city) were found to have been mutilated. In the ensuing panic Alcibiades was accused of being the originator of the sacrilege as well as of having profaned the Eleusinian Mysteries. He demanded an immediate inquiry, but his enemies, led by Androcles (the successor of Hyperbolus), ensured that he sailed with the charge still hanging over him. Shortly after reaching Sicily, he was recalled; but on the journey home he escaped and, learning that he had been condemned in absentia to death, went to Sparta. There he advised the Spartans to send a general to help the Syracusans and also to fortify Decelea in Attica, two serious blows to Athens. He also confirmed his reputation with women (which the rich Athenian whom he had married appreciated only too well) by seducing the wife of the Spartan king Agis II, who was at Decelea with his army.

In 412 Alcibiades helped stir up revolt among Athenian allies in Ionia, on the west coast of Asia Minor; but Sparta now turned against him, and he moved to Sardis to exercise his charm on the Persian governor. When some Athenian officers in the fleet began to plan an oligarchic coup, he held out hopes that if the democracy was overthrown he could secure financial support from Persia. In this he failed and, discarded by the oligarchs who had seized power, he was recalled by the Athenian fleet, which remained loyal to the democracy and needed his abilities. From 411 to 408 he helped Athens to a spectacular recovery, defeating the Spartan fleet in the Hellespont at Abydos (411) and Cyzicus (410) and regaining control over the vital grain route from the Black Sea.

These successes encouraged him to return in 407 to Athens, where he was welcomed with enthusiasm and given supreme control of the conduct of the war. In a typically bold gesture he led the procession to the Eleusinian festival by road in spite of the danger from the Spartan force at Decelea; but, in the same year, after a minor naval defeat in his absence, his political enemies persuaded the people to reject him, and he retired to a castle in Thrace. He remained, however, a disturbing influence on Athenian politics and destroyed any hopes of a political consensus. When the Athenians at Aegospotami (405) facing the Spartans in the Hellespont grew increasingly careless, he warned them of their danger. But he was ignored, and, when the Athenians lost their whole fleet in a surprise attack by the Spartan admiral Lysander, Alcibiades was no longer safe in his Thracian castle. He took refuge in Phrygia in northwestern Asia Minor with the Persian governor, who was induced by the Spartans to have him murdered.

Perhaps the most gifted Athenian of his generation, Alcibiades possessed great charm and brilliant political and military abilities but was absolutely unscrupulous. His advice, whether to Athens or Sparta, oligarchs or democrats, was dictated by selfish motives, and the Athenians could never trust him enough to take advantage of his talents. Moreover, the radical leader Cleon and his successors carried on a bitter feud with him, which at the critical period undermined Athenian confidence. Alcibiades could not practice his master's virtues, and his example of undisciplined and restless ambition strengthened the charge brought against Socrates in 399 of corrupting the youth of Athens. (Ru.M.)

BIBLIOGRAPHY. Plutarch's life of Alcibiades is a very readable combination of fact and fiction.

Alcidae, bird family, order Charadriiformes, which includes the birds known as auk, auklet, dovekie, guillemot, murre, murrelet, and puffin (*qq.v.*).

Alcindor, Lew (basketball player): *see* Abdul-Jabbar, Kareem.

Alcinous, in Greek mythology, king of the Phaeacians (on the legendary island of Scheria), son of Nausithoüs, and grandson of the god Poseidon. In the *Odyssey* he entertained Odysseus, who had been cast by a storm on the shore of the island. Scheria was identified in very early times with Corcyra, where Alcinous was revered as a hero. In the Argonautic legend, Alcinous lived on the island of Drepane, where he received Jason and Medea in their flight from Colchis.

Alciphron (fl. 2nd or 3rd century AD, Athens [Greece]), rhetorician who wrote a collection of fictitious letters, a form of literature popular in his day. More than 100 of the letters have survived. The background of them all is the Athens of the 4th century BC, and the imaginary writers are farmers, fishermen, and courtesans. The material of the letters is largely derived from the writers of the so-called New Comedy. They are written in an imitation of the pure Attic dialect and show traces of the influence of Alciphron's contemporary Lucian.

Alcira (city, Spain): *see* Alzira.

Alcithoë, in Greek legend, the daughter of Minyas of Orchomenus, in Boeotia. She and her sisters once refused to participate in Dionysiac festivities, remaining at home spinning and weaving. Late in the day Dionysiac music clanged about them, the house was filled with fire and smoke, and the sisters were metamorphosed into bats and birds. According to Plutarch, the sisters, driven mad for their impiety, cast lots to determine which one of their children they would eat. In retribution their female descendants were pursued at the Agrionia (an annual festival) by the priest of

Dionysus, who was permitted to kill the one he caught.

alclad, laminated metal produced in sheets composed of a Duralumin (*q.v.*) core and outer layers of aluminum.

Alcmaeon, also spelled **ALCMEON**, in Greek legend, the son of the seer Amphiaraus and his wife Eriphyle. When Amphiaraus set out with the expedition of the Seven Against Thebes, which he knew would be fatal to him, he commanded his sons to avenge his death by slaying Eriphyle (who had been bribed by Polyneices with the necklace of Harmonia to persuade her husband to fight) and by undertaking a second expedition against Thebes. After leading the Epigoni (the sons of the Seven) in the destruction of Thebes, Alcmaeon carried out his father's injunctions by killing his mother, but as a punishment he was driven mad and pursued by the Erinyes (goddesses of vengeance) from place to place.

On his arrival at Psophis in Arcadia, he was purified by its king, Phegeus, whose daughter Arsinoë (or Alpheisiboea) he married, making her a present of the fatal necklace and the robe of Harmonia, which brought misfortune to all who possessed them. The land was cursed with barrenness, and an oracle declared that Alcmaeon would not find rest until he reached a spot on which the sun had never shone at the time he slew his mother. Such a spot he found at the mouth of the Achelous River, where an island had recently been formed. There he settled and, forgetting his wife, married Callirrhoë, the daughter of the river god. Phegeus and his sons, however, pursued and killed Alcmaeon. On his death, Callirrhoë prayed that her two young sons might grow to manhood at once and avenge their father. Her prayer was granted, and her sons, Amphoterus and Acaman, slew Phegeus. After his death Alcmaeon was worshiped at Thebes; his tomb was at Psophis. His story was the subject of the modern parody "A Fragment of a Greek Tragedy," by A.E. Housman.

Alcmaeon, also spelled **ALCMEON** (fl. 6th century BC), Greek philosopher and physiologist of the academy at Croton (now Crotona, southern Italy), the first person recorded to have practiced dissection of human bodies for research purposes. He may also have been the first to attempt vivisection. Alcmaeon inferred that the brain was the centre of intelligence and that the soul was the source of life. Applying the Pythagorean principle of cosmic harmony between pairs of contraries, he posited that health consists in the isonomy (equilibrium) of the body's component contraries (*e.g.*, dry-humid, warm-cold, sweet-bitter), thus anticipating Hippocrates' similar teaching.

Alcmaeonid FAMILY, a powerful Athenian family, claiming descent from the legendary Alcmaeon, that was important in 5th- and 6th-century-BC politics. During the archonship of one of its members, Megacles (632? BC), a certain Cylon failed in an attempt to make himself tyrant, and his followers were slain at an altar sanctuary. Accused of sacrilege and murder, the Alcmaeonids incurred the bloodguilt that was to be used against them in political struggles for more than two centuries. The family was banished for the murder but returned during the ascendancy of Solon (early 6th century) to lead a party in Athens, which accepted Solon's reforms.

After Peisistratus became tyrant in 561-560, the Alcmaeonids, allied with the more conservative aristocrats, twice drove him from the city before he managed to have the family exiled. They were recalled later, and one of their members, Cleisthenes, was made archon for 525/524. Upon the murder of Peisistratus' son Hipparchus in 514, they were exiled once more by the tyrant Hippias. In 513 Cleisthenes led the Alcmaeonids in an unsuccessful invasion of Attica from their base in Boeo-

tia. The family was rewarded for rebuilding the fire-damaged temple of Apollo at Delphi when the Spartans, largely at the insistence of the Delphic oracle, finally drove out the Peisistratids in 510. Two years later Cleisthenes introduced a program of constitutional reforms that greatly furthered the development of Athenian democracy.

The policy followed by this opportunistic family during the next generation is obscure. They were suspected of collusion with the Persians at the Battle of Marathon (490), but the direct-line descendants were considerably less prominent after the Persian Wars. Both Alcibiades and Pericles, however, were descended from the family through their mothers. Spartan demands at the beginning of the Peloponnesian War for the expulsion of the Alcmaeonids were provocations directed at Pericles.

Alcman (fl. late 7th century BC, Sparta [Greece]), Greek poet, the first known writer of Dorian choral lyrics.

Alcman's work survives in fragments, the longest being a *parthenion* (a choir song for girls) discovered in a 1st-century papyrus in Egypt in 1855. In the *Suda* lexicon (late 10th century AD) Alcman is described as a man "of an extremely amorous disposition and the inventor of love poems." He was clearly a learned man, and his verse is full of geographic detail. One fragment, telling of the sleeping world at the end of the day, imitated by J.W. von Goethe in his *Wanderers Nachtlied*, is almost unique in Greek poetry for its sympathy with nature.

Alcman's light, gay manner, so different from the later Spartan style, gave rise to the tradition that he was not a native Spartan. He is thought by some to have come from Sardis in Lydia, but this is uncertain.

Alcoa, city, Blount county, eastern Tennessee, U.S. The city is a gateway to Great Smoky Mountains National Park. It was founded in 1913 by the Aluminum Company of America (Alcoa) on a tract of land known as North Maryville. In 1910 the first of a series of power dams was begun on the nearby Little Tennessee River and its tributaries. The purchase of these dams by the company led to the procurement of land north of the city of Maryville (*q.v.*) for plant sites. The community was developed as a planned industrial centre for the production of aluminum pig, ingots, sheet and plate, and aluminum powder and foil. Inc. 1919. Pop. (1990) 6,400.

Alcoa: *see* Aluminum Company of America.

Alcobaça, town and *concelho* (township), Leiria *distrito* ("district"), west-central Portugal. It lies at the confluence of the Alcoa and Baça rivers, just south-southwest of the city

Church of the Cistercian monastery, Alcobaça, Port.
Ernst A. Weber—Photo Researchers

of Leiria. Alcobaça is notable for its Cistercian monastery (Mosteiro de Santa Maria), founded in 1152 by King Afonso I in thanksgiving for the reconquest of Santarém from the Moors and rebuilt in the 13th century. During the Middle Ages the monastery rivaled the greatest European abbeys in size and wealth. It now houses the tombs of Portuguese royalty. The vast, austere abbey is early Gothic, with Baroque and later additions. Portions of the monastery's library are preserved in the public libraries of Lisbon and Braga. The economy of the town centres on fruit growing (began in the 12th century by the monks) and preserving, textile milling, and ceramic manufacturing. Pop. (1991 prelim.) town, 5,159; *concelho*, 53,880.

Alcock, Sir John William (b. Nov. 6, 1892, Manchester, Eng.—d. Dec. 18, 1919, Cotévrard, France), aviator who, with his fellow British aviator Arthur Brown, made the first nonstop transatlantic flight.

Alcock received his pilot's certificate in 1912 and joined the Royal Naval Air Service as an instructor at the opening of World War I. In 1916 he was posted to a wing group of the Eastern Mediterranean theatre, based

Sir John Alcock, detail of a portrait by Alex McEvoy, 1919; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

at Munros. During his service he performed many daring exploits, including the bombing of Constantinople. In September 1917 enemy antiaircraft fire forced him down into the sea near Suvla Bay (Anafarta Limani), near the Dardanelles, where he and his crew of two were taken prisoner by the Turks. He remained a prisoner until the end of the war and left the service in March 1919.

After the war he became a test pilot for Vickers Aircraft, which was preparing an airplane to fly the Atlantic Ocean nonstop for a £10,000 prize offered by the London *Daily Mail*. Alcock and Brown left St. John's, Nfld., at 4:13 PM GMT, on June 14, 1919. They landed the next day in a marshy bog near Clifden, County Galway, Ire., after a flight of 1,890 miles (3,040 km) in 16 hours 12 minutes. Both airmen were honoured throughout Great Britain and were created Knight Commanders, Order of the British Empire. They also received a prize of £10,000 from the London *Daily Mail*. Several months later, while delivering an amphibian aircraft to Paris, Alcock crashed in bad weather and was fatally injured.

alcohol, any of a class of organic compounds characterized by one or more hydroxyl (OH) groups attached to a carbon atom of an alkyl group (hydrocarbon chain). Alcohols may be considered as derivatives of water (H₂O) in

which one of the hydrogen atoms has been replaced by an alkyl group. Alcohols are among the most common organic compounds and are valuable intermediates in the synthesis of other compounds.

A brief treatment of alcohols follows. For full treatment, *see* MACROPAEDIA: Chemical Compounds.

Alcohols may be classified according to which carbon of the alkyl group is bonded to the hydroxyl group. In primary alcohols (RCH₂OH), the oxygen of the hydroxyl group is bonded to a carbon atom bearing at least two hydrogen atoms. In secondary alcohols (R₂CHOH), the hydroxyl group is bonded to a carbon attached to two other carbons, while in tertiary alcohols (R₃COH) it is bonded to a carbon attached to three other carbon atoms.

Most alcohols are colourless liquids or solids at room temperature: primary alcohols with fewer than 12 carbon atoms are liquid; those with 12 or more carbon atoms are solid. Polyhydric alcohols (those with more than one hydroxyl group) usually have the consistency of syrup. Alcohols with complex arrangements of carbon atoms, such as sterols, are usually solids. Alcohols of low molecular weight are highly soluble in water. With increasing molecular weight, alcohols become less soluble in water and their boiling points, vapour pressures, densities, and viscosities increase.

Primary alcohols may be oxidized to aldehydes or further to carboxylic acids, and secondary alcohols may be oxidized to ketones. When tertiary alcohols are oxidized, they decompose, breaking carbon-carbon bonds. Alcohols generally react with carboxylic acids to produce esters—neutral organic compounds found in fats and oils. Alcohols can also be converted to ethers and olefinic hydrocarbons.

Adding hydroxyl groups to an alcohol without increasing the number of carbon atoms changes many of its properties. In some cases, it may enhance sweetness, and the resultant alcohols are used as sweeteners. Alcohols with 8 to 12 carbon atoms have a characteristic roselike or lilylike odour and are used in making perfumes. In general, the most important industrial use of alcohols is as chemical intermediates, chiefly because alcohols can readily be converted into a large number of other compounds. This is done by simple chemical reactions to yield products such as fats and waxes—surface active agents used in detergents, plasticizers, emulsifiers, lubricants, emollients, and foaming agents.

Alcohols are among the more abundantly produced organic chemicals in industry. Some, such as ethanol and methanol, are utilized in great quantities. Ethanol, CH₃CH₂OH, also called ethyl alcohol, or grain alcohol, can be made by fermentation from the carbohydrates found in fruits, molasses, grains, and other agricultural products. It is also made industrially from ethylene, CH₂=CH₂. Ethanol is used in toiletries and pharmaceuticals and to sterilize hospital instruments. It is, moreover, the alcohol in alcoholic beverages. The anesthetic ether is also made from ethanol.

Methanol, also known as methyl alcohol, wood alcohol, or carbinol, can be manufactured from hardwood or from hydrogen and carbon monoxide (CO). It is used as a solvent, as a raw material for the manufacture of formaldehyde and special resins, in special fuels, in antifreeze, and for cleaning metals.

Methanol and ethanol are good fuels for automobile engines because they have high octane ratings and low pollution emission, though their solvent properties can cause problems by dissolving certain materials used in modern fuel systems. Gasohol, a solution of 10 percent ethanol in gasoline, is an alternative fuel that can be used in most automobiles without the solvency problem.

alcoholic beverage, any fermented liquor, such as wine, beer, or distilled liquor

(*qq.v.*), that contains ethyl alcohol, or ethanol (CH₃CH₂OH), as an intoxicating agent.

A brief treatment of alcoholic beverages follows. For full treatment, *see* MACROPAEDIA: Alcohol and Drug Consumption; Beverage Production.

Alcoholic beverages are fermented from the sugars in fruits, berries, grains, and such other ingredients as plant saps, tubers, honey, and milk and may be distilled to reduce the original watery liquid to a liquid of much greater alcoholic strength. Beer is the best-known member of the malt family of alcoholic beverages, which also includes ale, stout, porter, and malt liquor. It is made from malt, corn, rice, and hops. Beers range in alcoholic content from about 2 percent to about 8 percent. Wine is made by fermenting the juices of grapes or other fruits such as apples (cider), cherries, berries, or plums. Winemaking begins with the harvest of the fruit, the juice of which is fermented in large vats under rigorous temperature control. When fermentation is complete, the mixture is filtered, aged, and bottled. Natural, or unfortified, grape wines generally contain from 8 to 14 percent alcohol; these include such wines as Bordeaux, Burgundy, Chianti, and Sauterne. Fortified wines, to which alcohol or brandy has been added, contain 18 to 21 percent alcohol; such wines include sherry, port, and muscatel.

The making of distilled liquors begins with the mashes of grains, fruits, or other ingredients. The resultant fermented liquid is heated until the alcohol and flavourings vaporize and can be drawn off, cooled, and condensed back into a liquid. Water remains behind and is discarded. The concentrated liquid, called a distilled beverage, includes such liquors as whiskey, gin, vodka, rum, brandy, and liqueurs, or cordials. They range in alcoholic content usually from 40 to 50 percent, though higher or lower concentrations are found.

In the ingestion of an alcoholic beverage, the alcohol is rapidly absorbed in the gastrointestinal tract (stomach and intestines) because it does not undergo any digestive processes; thus, alcohol rises to high levels in the blood in a relatively short time. From the blood the alcohol is distributed to all parts of the body and has an especially pronounced effect on the brain, on which it exerts a depressant action. Under the influence of alcohol the functions of the brain are depressed in a characteristic pattern. The most complex actions of the brain—judgment, self-criticism, the inhibitions learned from earliest childhood—are depressed first, and the loss of this control results in a feeling of excitement in the early stages. For this reason, alcohol is sometimes thought of, erroneously, as a stimulant. Under the influence of increasing amounts of alcohol, the drinker gradually becomes less alert, awareness of his environment becomes dim and hazy, muscular coordination deteriorates, and sleep is facilitated. *See also* alcoholism.

Alcoholics Anonymous (AA), voluntary fellowship of alcoholic persons who seek to get sober and remain sober through self-help and the help of other recovered alcoholics. Although general conventions meet periodically and Alcoholics Anonymous World Services, Inc., is headquartered in New York City, all AA groups are essentially local and autonomous. To counteract self-indulgence and promote the group's welfare, members identify themselves only by first name and surname initial. Much of the program has a social and spiritual, but nonsectarian, basis.

AA began in May 1935 in the meeting of two alcoholics attempting to overcome their drinking problems: a New York stockbroker, "Bill W." (William Griffith Wilson [1895–1971]), and a surgeon from Akron, Ohio, "Dr. Bob S." (Robert Holbrook Smith [1879–1950]). Drawing upon their own experiences, they set out to help fellow alcoholics and first recorded their

program in *Alcoholics Anonymous* (1939; 3rd ed., 1976). By the late 20th century, Alcoholics Anonymous had some 2,000,000 members forming about 90,000 groups in 122 countries and territories (most of them, however, in the United States and Canada).

BIBLIOGRAPHY. Nan Robertson, *Getting Better: Inside Alcoholics Anonymous* (1988), provides a general survey and history of the organization.

alcoholism, repetitive intake of alcoholic beverages to such an extent that repeated or continued harm to the drinker occurs.

A brief treatment of alcoholism follows. For full treatment, see **MACROPAEDIA: Alcohol and Drug Consumption**.

Conceptions of what constitutes alcoholism vary with the traditional dietary use of alcohol and the social-drinking patterns of a community. Alcoholism may be viewed as a disease, a drug addiction, a learned response to crisis, a symptom of an underlying psychological or physical disorder, or a combination of these factors. The cause of alcoholism is equally uncertain. It has been viewed as a hereditary defect, a physical malfunction, a psychological disorder, a response to economic or social stress, or sin.

Manifestations of alcoholism vary with the individual. Intoxication may be followed by the relatively mild syndrome known as a hang-over; extreme symptoms of withdrawal may include delirium tremens, hallucinations, and other acute brain disorders. Polyneuropathy, a degenerative disease of the nervous system, and acute hepatitis are common. Alcoholics also suffer the consequences of a deficient diet. Cirrhosis of the liver is associated with chronic alcoholism, as are numerous forms of brain damage. Alcoholics also suffer high accident rates, lowered resistance to infection, loss of employment and family life, and a reduction in life span of 10 to 12 years.

Most approaches to the treatment of alcoholism require the alcoholic to recognize his illness and to abstain from alcohol. Treatment programs then vary according to the accepted definition and theory of cause of alcoholism. They include combinations of inpatient programs; general psychological rehabilitative treatments; organized self-help groups such as Alcoholics Anonymous (AA); the use of abstinence-maintaining drugs, such as Antabuse (disulfiram) and Temposil (citrated calcium cyanamide); injections of vitamins or hormones; and aversion therapy based on principals of behaviour modification.

Alcott, Bronson, in full **AMOS BRONSON ALCO**TT (b. Nov. 29, 1799, Wolcott, Conn., U.S.—d. March 4, 1888, Concord, Mass.), American philosopher, teacher, reformer, and member of the New England Transcendentalist group.

The self-educated son of a poor farmer, Alcott traveled in the South as a peddler before establishing a series of schools for children. His educational theories owed something to J.H. Pestalozzi, the Swiss reformer, but more to the examples of Socrates and the Gospels. His aim was to stimulate thought and “awaken the soul”; his method was conversational, courteous, and gentle. Questions of discipline were referred to the class as a group, and the feature of his school that attracted most attention, perhaps, was his scheme for the teacher’s receiving punishment, in certain circumstances, at the hands of an offending pupil, whereby the sense of shame might be instilled in the mind of the errant child.

These innovations were not widely accepted, and before he was 40 he was forced to close his last school, the famous Temple School in Boston, and sell its contents to ease his debts. In 1842 with money from Ralph Waldo Emerson he visited England, where a similar school founded near London was named Alcott House in his honour. He returned from England with a kindred spirit, the mystic

Charles Lane, and together they founded a short-lived utopian community, Fruitlands, in Massachusetts.

Bronson Alcott
Holman's Print Shop, Inc.

Alcott was a vegetarian, an Abolitionist, and an advocate of women’s rights; his thought was vague, lofty, and intensely spiritual. Always poor or in debt, he worked as a handyman or lived on the bounty of others until the literary success of his second daughter, Louisa May Alcott, brought him financial security.

The best of Alcott’s writing is available in *The Journals of Bronson Alcott* (1938), selected and edited by Odell Shepard.

Alcott, Louisa May (b. Nov. 29, 1832, Germantown, Pa., U.S.—d. March 6, 1888, Boston), American author known for her children’s books, especially *Little Women*.

A daughter of the Transcendentalist Bronson Alcott, Louisa spent most of her life in Boston and Concord, Mass., where she grew up in the company of Ralph Waldo Emerson, Theodore Parker, and Henry David Thoreau. Alcott realized early that her father was too impractical to provide for his wife and four daughters; after the failure of Fruitlands, a utopian community that he had founded, Louisa’s lifelong concern for the welfare of her family began. She taught briefly, worked as a domestic, and finally began to write, producing potboilers at first, and eventually more serious works. Alcott volunteered as a nurse after the American Civil War began. She contracted typhoid from unsanitary hospital conditions and was sent home. She was never completely well again, but the publication of her letters in book form, *Hospital Sketches* (1863), brought her the first taste of fame.

Her stories began to appear in *The Atlantic Monthly*, and, because family needs were pressing, she wrote the autobiographical *Little Women* (1868–69), which was an immediate success. Based on Alcott’s recollections of her own childhood, *Little Women* described the domestic adventures of a New England family of modest means but optimistic outlook. The book traces the differing personalities and fortunes of four sisters as they emerge from childhood and encounter the vicissitudes of employment, society, and marriage. *Little Women* created a realistic but wholesome picture of family life with which younger readers could easily identify. In 1869 Alcott was able to write in her journal: “Paid up all the debts . . . thank the Lord!” She followed up *Little Women*’s success with further domestic narratives drawn from her early experiences: *An Old-Fashioned Girl* (1870); *Aunt Jo’s Scrap Bag*, 6 vol. (1872–82); *Little Men* (1871); *Eight Cousins* (1875); *Rose in Bloom* (1876); and *Jo’s Boys* (1886).

Tired and in constant pain, she spent the last years of her life shadowed by the deaths of her mother and her youngest sister, May, who left behind a little daughter for Alcott to rear.

Alcott’s books for younger readers have remained steadfastly popular, and the republication of some of her less well known works late in the 20th century aroused renewed critical interest in her adult fiction.

A Modern Mephistopheles, which was published pseudonymously in 1877 and republished in 1987, is a Gothic novel about a failed poet who makes a Faustian bargain with his tempter. *Work: A Story of Experience* (1873), based on Alcott’s own struggles, tells the story of a poor girl trying to support herself by a succession of menial jobs. The Gothic tales and thrillers that Alcott published pseudonymously between 1863 and 1869 were collected

Louisa May Alcott, portrait by George Healy; in the Louisa May Alcott Memorial Association collection, Concord, Mass.

By courtesy of Louisa May Alcott Memorial Association

and republished as *Behind a Mask* (1975) and *Plots and Counterplots* (1976), and an unpublished Gothic novel written in 1866, *A Long Fatal Love Chase*, was published in 1995.

BIBLIOGRAPHY. Biographies include Martha Saxton, *Louisa May* (1977); and Ruth K. MacDonald, *Louisa May Alcott* (1983). Madeleine B. Stern (ed.), *Critical Essays on Louisa May Alcott* (1984); and Sarah Elbert, *A Hunger for Home: Louisa May Alcott’s Place in American Culture* (1987), offer criticism and interpretation. Alma J. Payne, *Louisa May Alcott* (1980), is a bibliography.

alcove, recess opening off a room or other space enclosed by walls or hedges. In medieval architecture it was commonly used as a sleeping space off the main body of a drafty hall. The separation of the alcove from the main space was accomplished at first by means of curtains and later by timber partitions to form independent rooms and thus conserve heat. In later centuries bed alcoves and kitchen alcoves reappeared as means of saving space in small living quarters, particularly in apartments.

Alcove also refers to spaces, often semicircular,

Alcove in the nymphaeum of the House of Neptune and Amphitrite, Herculaneum, Italy
Scala/Art Resource, New York City

lar in plan, hollowed out of thick walls and used for displaying statues, as found in Roman and Renaissance architecture.

Alcoy, town, Alicante *provincia*, in the *comunidad autónoma* (autonomous community) of Valencia, southeastern Spain. It lies in rugged foothills at the confluence of the two headstreams of the Serpis River, north of Alicante city. The site was settled before Roman times, but the present Alcoy was founded by the Moors, who named it Alcoyll after a city in Tunisia.

The town is a rail terminus and an important centre of the textile industry. A royal textile factory was established there in 1800, and it was the site of the first Spanish industrial school. Alcoy's manufactures include paper, especially for cigarettes, and metalworking and agricultural trade are also carried on. A fiesta, held in April on the Festival de San Jorge (St. George), Alcoy's patron, commemorates a 13th-century battle when the saint supposedly helped the Christians defeat the Moors; it is a tourist attraction. Pop. (1991 prelim.) 65,514.

Alcuin (b. c. 732, in or near York, Yorkshire, Eng.—d. May 19, 804, Tours, France), Anglo-Latin poet, educator, and cleric who, as head of the Palatine school established by Charlemagne at Aachen, introduced the traditions of Anglo-Saxon humanism into western Europe. He was the foremost scholar of the revival of learning known as the Carolingian Renaissance. He also made important reforms in the Roman Catholic liturgy and left more than 300 Latin letters that have proved a valuable source on the history of his time.

Alcuin's first 50 years were spent in Yorkshire, where he was first a pupil and, after 778, headmaster of the cathedral school of York, the most renowned of its day. He wrote a long poem, probably shortly before he left York, telling of the renowned men in that city's history. In 781 he met Charlemagne in Italy and accepted his invitation to Aachen, where the king was gathering the leading Irish, English, and Italian scholars of the age. The school, where Charlemagne himself, his family, his friends, and his friends' sons were taught, became a lively centre of discussion and exchange of knowledge. Alcuin introduced the methods of English learning into the Frankish schools, systematized the curriculum, raised the standards of scholarship, and encouraged the study of liberal arts for the better understanding of spiritual doctrine. In 796 he left the court to become abbot of the Abbey of St. Martin at Tours, where he encouraged the work of his monks on the beautiful Carolingian minuscule script, the ancestor of modern Roman typefaces.

Alcuin's formative influence in the development of Roman Catholicism in western Europe is ascribed mainly to his revision of the liturgy of the Frankish church. He was

Alcuin, medallion from the Bamberg Bible, 9th century; in the Bibliothèque Nationale, Paris
By courtesy of the Bibliothèque Nationale, Paris

responsible for the introduction of the Irish Northumbrian custom of singing the creed. He arranged votive masses for particular days of the week in an order still followed by Catholics, recited the Latin Vulgate, and wrote a number of works on education, theology, and philosophy.

Alcuin's life embodies contradictions. His leadership in church and state was remembered throughout the Middle Ages, yet he remained only a deacon. Though he was the foremost teacher in a rude age, his writings show no originality. He loved Charlemagne and enjoyed the king's esteem, but his letters reveal that his fear of him was as great as his love. Most of his poetry is mediocre. Toward the end of his life he acquired a great reputation for holiness, but he is not included in the canon of saints.

Aldabra Islands, atoll, one of the world's largest, in the Indian Ocean about 600 miles (1,000 km) southwest of the Seychelles group, and part of the Republic of the Seychelles. The Aldabras, together with Farquhar and Desroches islands and the Chagos Archipelago, formed part of the British Indian Ocean Territory from 1965 to 1976. The Aldabra Islands were formerly under the hegemony of the Seychelles, to which they were returned in June 1976, when that country gained its independence. They constitute an oval atoll (19 miles [30.5 km] long and 8 miles [13 km] wide) enclosing a large but shallow lagoon. Channels divide the ring into four low islands that rise to about 100 feet (30 m) above the sea and are called South Island (Grand Terre; the largest), West Island (Picard), Polymnie, and Middle Island (Malabar). In common with about half the other islands of Seychelles, the Aldabra Islands are volcanic in origin. Mangrove forests are found on the islands.

The Aldabras were once rich in guano (deposits formed from bird droppings), but it was almost all collected and sold for fertilizer in the early 1950s. South Island is famous for its giant tortoises, and a nature reserve established in 1976 completely protects them and other animals. The Aldabras were designated a World Heritage Site in 1982. The islands were uninhabited in the late 20th century.

Aldan River, river in eastern Siberia, Russia. It rises in the Stanovoy Range and flows northwestward in a huge curve to join the Lena River at Batamay. The Aldan River is 1,412 miles (2,273 km) long, the second largest tributary (after the Vilyuy) of the Lena, and drains more than 281,500 square miles (729,000 square km). Its annual discharge varies considerably both seasonally and annually. The river is navigable to Tommot but is frozen from mid-October to mid-May.

Aldebaran (Arabic: "The Follower"), also called ALPHA TAURI, reddish giant star in the constellation Taurus. Aldebaran is one of the 15 brightest stars, with an apparent visual magnitude of 0.86. Its diameter is approximately 50 times that of the Sun. It is accompanied by a very faint (13th magnitude) red companion star. Aldebaran lies about 50 light-years from the Earth. The star was once thought to be a member of the Hyades cluster, but in fact Aldebaran is 80 light-years closer to Earth. Aldebaran was probably named "The Follower" because it rises after the Pleiades cluster of stars.

Aldecoa, Ignacio (b. July 11, 1925, Vitoria, Spain—d. Nov. 15, 1969, Madrid), Spanish novelist whose work is noted for its local colour and careful composition.

Aldecoa studied at the University of Madrid, became a newspaper writer, and from 1947 to 1956 was a broadcaster for the radio station Voice of the Falange. He published essays on politics, several collections of short stories, and two books of poems, *Todavía la vida* (1947; "Life Goes On") and *Libro de las algas* (1949;

"Book of Algae"), before his first novels, *El fulgor y la sangre* (1954; "The Brightness and the Blood") and *Con el viento solano* (1956; "With the East Wind"). Aldecoa wrote about ordinary workers, their hopes, their fears, and the tendency of their lives toward monotony. He was adept at using the technical terms of different trades for artistic effect, including those of sailing in *Gran Sol* (1957; "Great Sun") and fishing in *Parte de una historia* (1967; "Part of a Story").

aldehyde, any of a class of organic compounds characterized by the presence of a carbonyl group, in which at least one of the two remaining bonds to the carbon atom is to a hydrogen atom. They have the general formula

where R is either a hydrogen atom or a hydrocarbon radical. Aldehydes are highly reactive, and much of their chemical activity comes from the nature of the carbonyl group.

A brief treatment of aldehydes follows. For full treatment, see MACROPAEDIA: Chemical Compounds.

The carbonyl group is highly polar. That is to say, it exhibits an uneven distribution of electrons, which renders the oxygen electrically negative and the carbon electrically positive. This increases the chemical activities of aldehydes and affects their physical properties as well.

Many aldehydes have characteristic, pleasant odours. They are prepared synthetically by a wide variety of methods. In principle, they are derived from alcohols by dehydrogenation (removal of hydrogen), from which process came the name aldehyde.

Aldehydes undergo a wide variety of chemical reactions. They are easily oxidized to acids and reduced to alcohols. Many nucleophiles (chemical species that seek positively charged centres) interact with the carbonyl carbon atom. Such reactions form the basis for important synthetic methods. For example, a hydrogen atom attached to the carbon atom immediately adjacent to the carbonyl group (the so-called alpha carbon atom) can be removed by acids or bases. The resulting carbon ion is a nucleophile that causes many useful reactions.

Aldehydes also undergo polymerization. The simpler aldehydes, such as formaldehyde and acetaldehyde, readily link together into chains containing tens of thousands of the molecule. The combination of these aldehydes with other types of molecules produces several familiar plastics. Bakelite, for example, is made from formaldehyde and phenol, and Formica is made from formaldehyde and urea.

Many aldehydes are manufactured on a large scale. They are useful as solvents, polymer components, perfume ingredients, and intermediates in the production of plastics, dyes, and pharmaceuticals.

Certain aldehydes are involved in physiological processes. Examples are retinal (vitamin A aldehyde), important in human vision, and pyridoxal phosphate, one of the forms of vitamin B₆. Formaldehyde prevents deterioration of substances rich in protein and is thus used as a preservative. Glucose and other so-called reducing sugars are aldehydes, as are several natural and synthetic hormones.

Alden, John (b. 1599?, England—d. Sept. 12, 1687, Duxbury, Mass. [U.S.]), one of the Pilgrims who in 1620 immigrated to America in the *Mayflower* and founded the Plymouth colony, the first permanent English colony in New England.

Alden was hired as a cooper by the London merchants who financed the expedition to the New World. He later moved from Plymouth

to a farm at nearby Duxbury, where he lived most of his life. From this base he served in a variety of civic capacities: agent for the colony, surveyor of highways, deputy from Duxbury, member of the local council of war, treasurer, and, most important, assistant to the governor of Massachusetts (1623–41 and 1650–86). During this time he twice served as deputy governor.

Two popular myths have combined to perpetuate a romantic aura about the memory of John Alden. One claimed he was the first Pilgrim to set foot on Plymouth Rock. The other was dramatized by Henry Wadsworth Longfellow's poem "The Courtship of Miles Standish," in which Alden presumably won the hand of Priscilla Mullens after first wooing her for his friend Standish. He did wed Priscilla in 1623, and the marriage produced 11 children. When he died, he was the last male survivor of the Mayflower Company.

alder, any of about 30 species of ornamental shrubs and trees constituting the genus *Alnus*, in the birch family (Betulaceae), distributed throughout the Northern Hemisphere and western South America on cool, wet sites at elevations up to 2,500 m (8,200 feet).

Alder (*Alnus glutinosa*)
Earl L. Kubis—Root Resources

An alder may be distinguished from a birch by its usually stalked winter buds and by cones that remain on the branches after the small, winged nutlets are released. The scaly bark is grayish brown in some species and almost white in others. The oval leaves are alternate, serrate, and often shallowly lobed; sticky on unfolding but glossy when mature, they fall without changing colour. Male and female flowers are borne in separate catkins on the same tree; they form during the summer and usually blossom the following spring before the leaves open.

Familiar North American alders are the red alder (*A. rubra*, or *A. oregona*), a tall tree whose leaves have rusty hairs on their lower surfaces; the white, or Sierra, alder (*A. rhombifolia*), an early-flowering tree with orange-red twigs and buds; the speckled alder (*A. rugosa*), a small tree with conspicuous whitish, wart-like, porous markings, or lenticels; the aromatic-leaved American green alder (*A. crispa* or *A. mitchelliana*); the closely related but taller Sitka alder (*A. sinuata*); and the mountain, or thinleaf, alder (*A. tenuifolia*), a shrubby tree with yellow or orange-brown midribs on its leaves and a domelike crown of pendulous branches.

The European alder (*A. glutinosa*), sometimes known as black alder for its dark bark and cones, is widespread throughout Eurasia and is cultivated in several varieties in North America. The name black alder is also applied to winterberry, a type of holly. The green alder (*A. viridis*), a European shrub, has sharply pointed, bright-green leaves. The white alder (*A. incana*) includes several varieties useful as an ornamental.

Alders are practically immune to diseases other than fungal attacks. Usually propagated

by seed, they may also be cultivated from cuttings or suckers.

Alder wood, pale yellow to reddish brown, is fine-textured and durable, even under water; it is useful for furniture, cabinetry, turnery, and in charcoal manufacture and millwork. Red and European alders are important timber trees. European, Italian, Japanese, Manchurian, speckled, and seaside alders are popular ornamentals. Because of their spreading root systems and tolerance of moist soils, alders are often planted on stream banks for flood control and the prevention of erosion. They are among the first woody plants to appear in denuded areas; although short-lived, they prepare the soil for more enduring trees by increasing its organic matter and nitrogen content.

Alder, Kurt (b. July 10, 1902, Königshütte, Prussia—d. June 20, 1958, Cologne), coreipient, with Otto Diels, of the Nobel Prize for Chemistry of 1950 for their development of a widely used method of synthesizing cyclic organic compounds. They gave the first experimental proof of the nature of the reaction and demonstrated its application to the synthesis of a wide range of ring compounds.

Alder studied chemistry at the universities of Berlin and Kiel, where he received his doctorate in 1926. He and Diels wrote their first paper on the reaction of dienes with quinones in 1928. Alder was a professor of chemistry at Kiel from 1934 to 1936. He applied his fundamental research to the development of plastics while working as a research director for IG Farben (1936–40), then the world's largest chemical concern. In 1940 he became professor of chemistry and director of the chemical institute at the University of Cologne.

alder buckthorn (*Rhamnus frangula*), also called **ALDER DOGWOOD** (*Rhamnus frangula*), woody shrub or small tree, of the buckthorn family (Rhamnaceae), native to western Asia, Europe, and northern Africa. It has been introduced into North America and other regions, where it is often cultivated as an ornamental. The plant grows rapidly, reaching a height of

Alder buckthorn (*Rhamnus frangula*)
Sven Samelius

5.5 m (about 18 feet); its dark, dense, and lustrous foliage turns yellow in autumn. The alternate, rather oval leaves are 3.75–6 cm (1½–2½ inches) long. Small, white flowers are borne in clusters of 2 to 10. The small fruit turns from red to black. Tallhedge buckthorn (*Rhamnus frangula* 'Columnaris') is a horticultural variety grown for its low maintenance and upright form.

alderfly, any insect of the megalopteran family Sialidae, characterized by long, filamentous antennae and two pairs of large wings (anterior wing length 20 to 50 mm [¾ inch to 2 inches]), membranous and well-developed, with part of the hind wing folding like a fan. The adult alderfly is dark-coloured, 15 to 30

mm (¾ inch to 1½ inches) long, sluggish, and a weak flier. It usually inhabits shore vegetation, especially alder trees.

Alderfly (*Sialis*)
N.A. Callow—EB Inc

The aquatic larvae, which have biting jaws and seven or eight pairs of filamentous abdominal gills, crawl along the bottoms of ponds and streams and feed on small insects. Pupae are found in soil and moss. The life cycle is completed in one year.

Consult the INDEX first

alderman, member of a municipal legislative body in England and the United States. In early English law there were up to 11 classes of aldermen. Among the Anglo-Saxons, earls, governors of provinces, and other persons of distinction received the title; later it was used to designate the chief magistrate of a county or group of counties.

Until 1972, English county councils had two types of members—councillors and aldermen; except in the government of the City of London, the office of alderman was abolished throughout England after 1972.

In the American colonial period, city councils resembled their British prototypes, in which aldermen and common councillors characteristically sat together as one body under the chairmanship of the mayor. In most colonial boroughs both the aldermen and the councilmen were chosen by the voters, but in a few cases only councilmen were elected, the aldermen being selected by the councilmen as in England. Following the colonial period, all members of the council, including aldermen, were elected by popular vote. The title alderman came to refer to members of the council in cities governed by mayors and councils; in other forms of city government the term commissioners or councilmen is ordinarily used. Aldermen, as opposed to councilmen and commissioners, are usually elected by wards rather than in city-wide contests.

Alderney, French AURIGNY, one of the Channel Islands (*q.v.*), in the English Channel, with an area of 3 square miles (8 square km), separated from the Normandy coast (Cap de la Hague) by the dangerously swift 10-mile (16-kilometre) Race of Alderney. Swinge Race, on the west, separates it from the uninhabited Burhou, Ortac, and smaller islets, beyond which the notorious Casquets, a group of jagged rocks, carry a lighthouse. The nearest English coast is 55 miles (88 km) north.

The island is a tableland that is mostly above 200 feet (60 m) and little-dissected. Steep cliffs rise to 275 feet (83 m) on the south and west coasts, while old cliffs rise behind raised beaches on the north and east. The two main inlets are Braye Harbour, protected by a 1,000-yard (914-metre) breakwater on the north, and Longy Bay (southeast), backed by an almost-filled lagoon.

The earliest known inhabitants were builders of megalithic tombs. The Bronze Age is well-represented, and the Romans appear to have built a small fort (the Nunnery) on the island. From the 11th century it was part of the Norman domain and was occupied by the

French from 1338 to 1340. In 1559 it was leased to George Chamberlain and granted (1584) by letters patent to his brother John, who transferred it to the earl of Essex; his descendants held it until the English Civil War. From the Restoration until 1825, the government of Alderney was separated from that of Guernsey, being granted in 1660 to Edward de Carteret, who transferred it in 1661 to Sir George Carteret. Sir George's widow sold it to Edmund Andros of Guernsey (c. 1682), from whom it descended to the Le Mesurier family. Alderney is now in the Bailiwick of Guernsey (*qv*) but has its own local administration. Under the reformed constitution of 1949, the president and States of Alderney (nine members) are popularly elected; the Court of Alderney administers justice. During the 19th century, the island was heavily fortified by the British, who maintained a garrison there until 1930. Repatriation of the Alderney community, evacuated to England in 1940 prior to German occupation, was carried out after the war. As a result it was necessary to re-create the island's economy, based mainly on dairy farming and tourism. Most inhabitants live in the only town, St. Anne's, overlooking Braye Harbour; Newtown forms an appendage at a lower level. Communications are through Guernsey, to which Alderney is linked by air and shipping services. Pop. (1994 est.) 2,375.

Aldfrith (d. Dec. 14, 704, Driffield, Eng.), king of Northumbria (685–704) and patron of literature. An illegitimate son of Oswiu, he succeeded to the throne when his brother Ecgfrith was killed at the Battle of Nechtansmere. Educated for the priesthood, he stimulated the growth of scholarship in Northumbria during his reign, producing conditions under which the historian Bede flourished.

Aldhelm (c. 639–709), West Saxon abbot of Malmesbury, the most learned teacher of 7th-century Wessex, a pioneer in the art of Latin verse among the Saxons, and the author of numerous extant writings in Latin verse and prose. He was trained in Latin and in Celtic-Irish scholarship by Malmesbury's Irish founder and went on to study at the famous School of Canterbury, where he was exposed to continental influences. He read widely in Latin poetry and prose, pagan as well as sacred; he learned Greek; he followed the arithmetic and astronomy of his day; and he experimented with various forms of poetic metre. In about 675 he became abbot of Malmesbury, where he remained, carrying on a threefold work, as monk and priest, as encourager of learning, and as Latin poet. In 705 he was consecrated bishop of Sherborne. He was also a popular vernacular poet, though none of that verse survives.

In addition to his pastoral duties, building churches, and founding monasteries, Aldhelm wrote vigorous letters of encouragement to other scholars, the style of which betrays his Celtic training. In similar prose he also wrote a lengthy treatise on the celibate life for the nuns of Barking. Its flood of learning and its difficult style so delighted the community that he made a second version of it in Latin hexameters.

Metrical science was Aldhelm's special preoccupation, and his most famous work is a treatise on metrics sent to his friend Aldfrith, king of Northumbria (685–704). It includes as examples 100 *aenigmata* (riddles) of Aldhelm's own invention in Latin hexameters, which served as models for such 8th-century Saxon writers as Tatwine, archbishop of Canterbury, and St. Boniface, apostle of Germany.

Aldington, Richard, original name EDWARD GODFREE ALDINGTON, (b. July 8, 1892, Hampshire, Eng.—d. July 27, 1962, Sury-en-Vaus,

Fr.), poet, novelist, critic, and biographer who wrote searingly and sometimes irascibly of what he considered to be hypocrisy in modern industrialized civilization.

Educated at Dover College and London University, he early attracted attention through his volumes of Imagist verse (*see Imagists*). In 1913 he married Hilda Doolittle (H.D.), the U.S. Imagist poet. His best and best known novel, *Death of a Hero* (1929), to which *All Men Are Enemies* (1933) was a sequel, reflected the disillusionment of a generation that had fought through World War I. In *The Colonel's Daughter* (1931) he satirized sham gentility and literary preciousness so outspokenly that two lending libraries refused to handle the novel. In his long poems *A Dream in the Luxembourg* (1930) and *A Fool in the Forest* (1925) he inveighed against the mechanization of modern man more lyrically, with bittersweet romanticism, and his translations from ancient Greek and Latin poets revealed his love for earlier civilizations.

His critical works, uneven in quality, included *Literary Studies* (1924) and *French Studies* (1925) and biographies of Voltaire, D.H. Lawrence, Norman Douglas, and Wellington. *Lawrence of Arabia* (1955), one of his last books, was an uncompromising attack on T.E. Lawrence. Late in life Aldington became a best-seller in the U.S.S.R., where he celebrated his 70th birthday. *A Passionate Pilgrim: Letters to Alan Bird from Richard Aldington, 1949–1962* was published in 1975.

Aldiss, Brian W(ilson) (b. Aug. 18, 1925, East Dereham, Norfolk, Eng.), prolific English author, chiefly of science fiction, whose novels and short stories display considerable range in style and approach.

He served with the British Army (1943–47), part of the time in the Royal Corps of Signals, then was a bookseller until 1956, meanwhile publishing *The Brightfount Diaries* in 1955. Aldiss has also been an influential anthologist of science fiction. Many collections of his stories are available, including *Best Science Fiction Stories of Brian W. Aldiss* (1965) and *A Brian Aldiss Omnibus* (1969 and 1971). Outstanding individual volumes of stories include *Hothouse* (1962) and *The Saliva Tree* (1966). Notable departures from science fiction were his autobiographically based *The Hand-Reared Boy* (1970) and *A Soldier Erect* (1971). Later fiction includes *A Rude Awakening* (1978), *Life in the West* (1980), and *Moreau's Other Island* (1980; also published as *An Island Called Moreau*, 1981).

Aldobrandini, Ippolito (pope): *see* Clement VIII.

aldosterone, a steroid hormone secreted by the adrenal gland. It serves as the principal regulator of the salt and water balance of the body (a mineralocorticoid) and has a small effect on the metabolism of fats, carbohydrates, and proteins.

Aldosterone is synthesized in the body from corticosterone, a steroid derived from cholesterol. Production of aldosterone (in adult humans, about 20–200 micrograms per day) in the zona glomerulosa of the adrenal cortex is apparently regulated by renin-angiotensin secreted from the kidney in response to variations in blood pressure and volume, and plasma sodium and potassium levels. It influences salt and water retention by an effect on the proximal tubules of the kidney.

Pure aldosterone was isolated from beef adrenals in 1953 by collaborating groups in England and Switzerland; by 1956 its structure was established and it was synthesized from other steroids. There are several preparative procedures, but the high cost of the hormone and the availability of other mineralocorticoids greatly restrict its use in therapy.

Aldred (Anglo-Saxon archbishop): *see* Ealdred.

Aldrich, Nelson W(ilmarth) (b. Nov. 6, 1841, Foster, R.I., U.S.—d. April 16, 1915, New York City), U.S. senator and financier whose work on the Aldrich-Vreeland Currency Act of 1908 and chairmanship of the National Monetary Commission (1908–12) helped prepare the way for the Federal Reserve Act of 1913.

Aldrich rose from the Providence Common Council through the Rhode Island legislature to the U.S. Congress (representative 1879–81; senator 1881–1911). Meanwhile, he amassed a modest fortune through investments in banking, electricity, gas, rubber, and sugar.

Nelson Aldrich, 1902

By courtesy of the Library of Congress, Washington, D.C.

In Congress, Aldrich was principally associated with the defense of the protective tariff and the gold standard, and opposition to any meaningful regulation of business. He emerged as the leader of the small coterie of Senate Republicans who dominated the party caucus and therefore determined the action of the Senate on most issues between 1895 and 1910. Through his influence the Interstate Commerce Act of 1887 and the Sherman Anti-Trust Act of 1890 were modified in a conservative direction.

The standard biography is N.W. Stephenson's *Nelson W. Aldrich, a Leader in American Politics* (1930).

Aldrich, Thomas Bailey (b. Nov. 11, 1836, Portsmouth, N.H., U.S.—d. March 19, 1907, Boston), poet, short-story writer, and editor whose use of the surprise ending influenced the development of the short story. He drew upon his childhood experiences in New Hampshire in his popular classic *The Story of a Bad Boy* (1870).

Aldrich left school at 13 to work as a merchant's clerk in New York City and soon began to contribute to various newspapers and magazines. After publication of his first book of verse, *The Bells* (1855), he became junior literary critic on the *New York Evening Mirror* and later subeditor of the *Home Journal*. From 1881 to 1890 he was editor of *The Atlantic Monthly*.

His poems, which reflect the cultural atmosphere of New England and his frequent European tours, were published in such volumes as *Cloth of Gold* (1874), *Flower and Thorn* (1877), *Mercedes and Later Lyrics* (1884), and *Windham Towers* (1890).

His best known prose is *Marjorie Daw and Other People* (1873), a collection of short stories.

Aldridge, Ira Frederick (b. 1805, New York City or Belair, Md., U.S.—d. Aug. 10, 1867, Łódź, Pol.), black tragedian, considered one of the greatest interpreters of his day.

Accounts of his life in the United States are conflicting. The great British actor Edmund Kean is believed to have engaged him as a personal attendant while visiting the United States; they returned together to England, where Kean encouraged Aldridge to study for the stage. In 1826 he made a highly successful debut in London as Othello. Billed as

Aldridge, detail from an engraving by T. Hollis, 1833

By courtesy of the Victoria and Albert Museum, London

the "African Roscius," after the great Roman comic actor, he made triumphant tours of Europe in several Shakespearean roles, including Othello, King Lear, and Macbeth. After 1853 he played mostly on the Continent, receiving honours from the Emperor of Austria, in Switzerland, and in Russia, among others.

It is doubtful that Aldridge ever returned to the United States; he became an English citizen in 1863.

aldrin, one of the several isomers (compounds with the same composition but different structures) of hexachlorohexahydrodimethanonaphthalene, a chlorinated hydrocarbon used as an insecticide. Aldrin was first prepared in the late 1940s and is manufactured by the reaction of hexachlorocyclopentadiene with bicycloheptadiene (both derived from hydrocarbons obtained from petroleum). Aldrin stimulates the central nervous system and is toxic to warm-blooded animals; poisoning can result from ingestion, inhalation, or absorption through the skin.

The insecticide dieldrin is made from aldrin by treatment with peroxyacetic acid.

Isodrin, a stereoisomer of aldrin, is made from cyclopentadiene and hexachlorobicycloheptadiene; it has insecticidal properties similar to those of aldrin and can be treated with peroxyacetic acid to form another insecticide, endrin, a stereoisomer of dieldrin. Aldrin, dieldrin, isodrin, and endrin, along with other chlorinated hydrocarbons, are being discontinued as insecticides because of their injurious effects on other animals that become exposed to them.

Aldrin, Edwin Eugene, Jr., byname BUZZ ALDRIN (b. Jan. 20, 1930, Montclair, N.J., U.S.), astronaut who set a record for extravehicular activity and was the second man to set foot on the Moon.

Aldrin, 1969

By courtesy of the National Aeronautics and Space Administration

A graduate of the U.S. Military Academy, West Point, N.Y. (1951), Aldrin became an air force pilot. He flew 66 combat missions in Korea and later served in West Germany. In 1963

he wrote a dissertation on orbital mechanics to earn his Ph.D. from the Massachusetts Institute of Technology, Cambridge. Later that year he was chosen as an astronaut.

On Nov. 11, 1966, he joined James A. Lovell, Jr., on the four-day Gemini 12 flight. Aldrin's 5½-hour walk in space proved that man can function effectively in the vacuum of space.

Apollo 11, manned by Aldrin, Neil A. Armstrong, and Michael Collins, was launched to the Moon on July 16, 1969. Four days later, Armstrong and Aldrin landed near the edge of Mare Tranquillitatis. After spending about two hours in gathering rock samples, taking photographs, and setting up scientific equipment for tests, the astronauts concluded their excursion on the surface. Armstrong and Aldrin later piloted the Lunar Module to a successful rendezvous with Collins and the Command Module in lunar orbit. The mission ended on July 24, with splashdown in the Pacific Ocean.

Aldrin retired from the National Aeronautics and Space Administration in 1971 to become commandant of the Aerospace Research Pilots' School at Edwards Air Force Base, California. In March 1972 he retired from the Air Force to enter private business. He wrote an autobiographical book, *Return to Earth* (1973).

Aldrovandi, Ulisse (b. Sept. 11, 1522, Bologna, Bologna—d. May 4, 1605, Bologna), Renaissance naturalist and physician noted for his systematic and accurate observations of animals, plants, and minerals.

After studying mathematics, Latin, law, and philosophy, Aldrovandi went to Padua in about 1545 to continue his studies. There he began to study medicine, the field in which he eventually earned a degree in 1553. On his return to Bologna in 1549 he was arrested, charged with heresy, and sent to Rome, where he was able to exonerate himself, probably in part because of his noble parentage. Returning to the University of Bologna, he was made a full professor in 1561 as a result of the great interest in his lectures, in which he presented natural history as a systematic study. He founded a botanical garden at Bologna and was named curator. His appointment as inspector of drugs and pharmacies met opposition, but Pope Gregory XIII confirmed the appointment. The official pharmacopoeia that Aldrovandi wrote, *Antidotarii Bononiensis Epitome* (1574), describing the constituents and properties of drugs, became a model for such works.

Pope Gregory XIII gave Aldrovandi financial assistance in publishing his numerous works on natural history, which included detailed observations of the day-to-day changes occurring in the incubation of the chicken embryo. Only four volumes, with detailed copperplate engravings, appeared during his lifetime; the remainder were prepared by his students from only a portion of his manuscripts. He also wrote *Le antichità della città di Roma* (1556), an account of various statues in Rome. His museum of biological specimens, classified according to his own system and left to the city of Bologna at his death, contributed to the later development of animal taxonomy.

ale, fermented malt beverage, full-bodied and somewhat bitter, with strong flavour of hops. Popular in England, where the term is now synonymous with beer, ale was until the late 17th century an unhopped brew of yeast, water, and malt, beer being the same brew with hops added. Modern ale, usually brewed with water rich in calcium sulfate, is made with top-fermenting yeast and processed at higher temperatures than the lager beers popular in the United States. Pale ale has up to 5 percent alcohol content; the darker strong ale contains up to 6.5 percent.

ale cost (herb): see costmary.

Aleandro, Girolamo, Dutch HIERONYMUS ALEXANDER (b. Feb. 13, 1480, Motta di Treviso, near Venice—d. Feb. 1, 1542, Rome), cardinal and Humanist who was an important opponent of the Lutheran Reformation.

A remarkable scholar, particularly of classical languages, Aleandro was in his youth closely associated with the Dutch Humanist Erasmus. He lectured at Venice, Orléans (France), and Paris, where he was appointed rector of the university.

Aleandro, detail of an engraving by an unknown artist

BBC Hulton Picture Library

In 1520 Pope Leo X sent him to Germany to lead the opposition against Martin Luther at the Diet of Worms, an effort that brought about his break with Erasmus. The edict against Luther, which was adopted by the Diet, was drawn up and proposed by Aleandro, and in Brussels it was Aleandro who was responsible for the death of the first martyrs of the Reformation. In 1523 Clement VII sent him as nuncio to the court of Francis I of France, with whom he was taken prisoner at the Battle of Pavia (1525). He was later employed on various papal missions, especially to Germany, but was unable to check the progress of the new doctrines. He was created cardinal in 1538 by Paul III.

Aleandro's chief work is his unfinished treatise *De habendo Concilio*, setting forth his views on the Council of Trent, of which he was an ardent supporter. This and other documents of Aleandro in the Vatican Library, relating to his opposition to Luther, were used in Sforza Pallavicino's *Istoria del Concilio Tridentino* (1656; "History of the Council of Trent").

Aleardi, Aleardo, Conte (Count), original name GAETANO ALEARDI (b. Nov. 4, 1812, Verona, Austria—d. July 17, 1878, Verona, Italy), poet, patriot, and political figure, an archetype of the 19th-century Italian poet-patriots. His love poems and passionate diatribes against the Austrian government brought him renown.

Brought up in Verona, then controlled by Austria, he studied law at the University of Padua. His love lyrics, *Le lettere a Maria* (1846; "The Letters to Maria"), were eagerly read; but back in Verona and prevented by the Austrian government from practicing law, he wrote a series of bitterly anti-Austrian poems, notably *Le città italiane marinare e commercianti* (1856; "The Maritime and Commercial Italian Cities"), *Il tre fiumi* (1857; "The Three Rivers"), and *I sette soldati* (1861; "The Seven Soldiers"). He also edited, with the poet Giovanni Prati, an outspoken journal, *Il Caffè Pedrocchi*. The Austrians imprisoned him twice (1852 and 1859) and finally sent him into exile.

When the Austrians were expelled in 1866,

Aleardi returned to Verona and became its representative to the Italian parliament after Verona joined the Kingdom of Italy in 1866. He later became a senator and remained in public life until his death.

aleatory dance, composition made up of steps freely improvised in the course of the dance; or, in a more specialized sense, of choreographed items selected at random, sometimes by a computer. The *Suite by Chance* (1952), by Merce Cunningham, was the first composition by random choreography.

aleatory music (from Latin *alea*, "dice"), also called CHANCE MUSIC, 20th-century music in which chance or indeterminate elements are left for the performer to realize. The term is a loose one, describing compositions with strictly demarcated areas for improvisation according to specific directions and also unstructured pieces consisting of vague directives, such as "Play for five minutes."

The indeterminate portion of aleatory music commonly occurs in two areas. The performers may be told to arrange the structure of the piece—e.g., by reordering its sections or by playing sections simultaneously as they wish. The musical score may also indicate points where performers are to improvise or even to include quasi-theatrical gestures. Such requirements may give rise to inventive notation, including brackets enclosing a blacked-out space, suggesting pitch area and duration of the improvisation. Among notable aleatory works are *Music of Changes* (1951) for piano and *Concert for Piano and Orchestra* (1958), by the American composer John Cage, and *Klavierstück XI* (1956; *Keyboard Piece XI*), by Karlheinz Stockhausen of Germany.

Alecsandri, Vasile (b. June 14, 1821, Bacău, Moldavia—d. Aug. 22, 1890, Mircești, Rom.), lyric poet and dramatist, the first collector of Romanian popular songs and a leader of the movement for the union of the Romanian principalities.

Alecsandri was educated at Iași and subsequently in Paris (1834–39). He published his first collection of folk songs in 1844 and was also active in the Romanian revolutionary cause.

His lyrical poems, *Doine și lăcrimioare*, appeared in Paris in 1853, and during 1852–53 he published at Iași two volumes of ballads and songs. In 1868–75 he published his descriptive poems of landscapes, entitled *Pasteluri*. As a playwright he created Romanian social comedy, but his most important contributions to the theatre were his poetic dramas: *Despot Vodă* (1879), *Fântâna Blanduziei* (1883; "Blanduzia's Fountain"), and *Ovidiu* (1885; "Ovid").

In later life Alecsandri played an important part in his country's affairs. As minister for foreign affairs (1859–60), he went to London as Prince Alexandru Cuza's special envoy to seek British recognition of the United Romanian Principalities. In 1885 he was appointed Romanian minister in Paris.

Alegre, Caetano da Costa: see Costa Alegre, Caetano da.

Alegrete, city, western Rio Grande do Sul estado ("state"), Brazil. It lies along the Ibirapuitã River at 292 feet (89 m) above sea level. It was founded in 1817 and given city status in 1857. The *município* ("municipality") of which Alegrete is the seat supports large cattle herds and substantial numbers of sheep. The city is a meat-processing centre. A railroad junction west of Pôrto Alegre, it can also be reached by highway and by air. Pop. (2000 prelim.) 75,091.

Alegría, Ciro (b. Nov. 4, 1909, Saltimbanca, Peru—d. Feb. 17, 1967, Lima), Peruvian nov-

elist who wrote about the lives of the Peruvian Indians.

Educated at the National College of San Juan, Alegría acquired a firsthand knowledge

Alegría, 1941
UPI

of Indian life in his native province of Huamachuco; this first appeared in his novel *La serpiente de oro* (1935; *The Golden Serpent*), which portrays the diverse human life to be found along the Marañón River in Peru. *Los perros hambrientos* (1938; "The Hungry Dogs") describes the difficulties faced by the sheepherding Indians of the Peruvian highlands. The novel that is generally considered Alegría's masterpiece is *El mundo es ancho y ajeno* (1941; *Broad and Alien is the World*). It depicts in epic manner the struggles of an Indian tribe to survive in the Peruvian highlands against the greed of land-hungry white men. A collection of short fiction (*Duelo de caballeros* [1963]) and *Novelas completas* (1963) were his last works.

In 1930 Alegría joined the militantly pro-Indian Alianza Popular Revolucionaria Americana, whose members were called Apristas, and became an active agitator for social reform. He was twice jailed, in 1931 and 1933, for illegal political activity and was exiled to Chile in 1934. From 1941 to 1948 Alegría lived in the United States, but in 1948 he returned to Peru, where he resided until his death.

Aleichem, Sholem: see Sholem Aleichem.

Aleijadinho, byname of ANTÔNIO FRANCISCO LISBOA (b. Aug. 9, 1738?, Villa Rica, Brazil—d. Nov. 18, 1814, Mariana), prolific and influential Brazilian sculptor and architect whose Rococo statuary and religious articles complement the dramatic sobriety of his churches. He was of Portuguese and black ancestry.

Aleijadinho was born deformed (his sobriquet means "Little Cripple"). He eventually lost the use of his hands and finally became blind, but he worked tirelessly, nonetheless, with tools strapped to his wrists, until the end of his long life. He designed, built, and decorated the sanctuary of Bom Jesus de Matozinhos, Congonhas do Campo (1757–77), and the Church of São Francisco, Ouro Prêto (1766–94).

Aleixandre, Vicente (b. April 26, 1898, Seville—d. Dec. 14, 1984, Madrid), Spanish poet, a member of the Generation of 1927, who received the Nobel Prize for Literature in 1977. He was strongly influenced by the Surrealist technique of poetic composition.

Aleixandre was the son of a railway engineer. He studied law and business management and from 1920 to 1922 taught commercial law. He became seriously ill in 1925 and during his convalescence wrote his first poems. He remained in Spain during the Spanish Civil War although his poetry was banned from

1936 to 1944. In 1949 Aleixandre was elected to the Spanish Royal Academy.

Aleixandre was considered a master of free verse, the style that appears in his first major book, *La destrucción o el amor* (1935; "Destruction or Love"), which was awarded the National Prize for Literature. In this work the poet explored the theme of human identification with the physical cosmos. Similar themes appear in *Sombra del paraíso* (1944; "Shadow of Paradise"). A greater emphasis upon human life is found in *Historia del corazón* (1954; "History of the Heart") and *En un vasto dominio* (1962; "In a Vast Domain"), works that deal with time, death, and human solidarity.

Aleixandre's later poetry is of a metaphysical nature; he explores death, knowledge, and experience in *Poemas de la consumación* (1968; "Poems of Consummation") and *Diálogos del conocimiento* (1974; "Dialogues of Insight").

In addition to writing poetry of great originality and depth, Aleixandre published the prose work *Los encuentros* (1958; "The Meetings"), a book of fond sketches of his fellow writers.

Alekhine, Alexander, Alekhine also spelled ALEKHIN, or ALJECHIN, original name ALEKSANDR ALEKSANDROVICH ALYOKHIN (b. Nov. 1, 1892, Moscow—d. March 24, 1946, Estoril, Port.), world-champion chess player from 1927 to 1935 and from 1937 until his death, noted for using a great variety of attacks.

Alekhine was a precocious chess player, becoming a master at age 16 and a grand master at age 22. He was playing in a tournament in Mannheim, Ger., when World War I broke out, and he escaped from internment to serve in the Red Cross division of the Russian army.

After the Russian Revolution of 1917, Alekhine became a naturalized French citizen and studied law at the University of Paris. In 1927, after a contest lasting nearly three months, he won the world championship from José Raúl Capablanca of Cuba. Eight years later he lost the title to Max Euwe of The Netherlands, but he regained it from Euwe in 1937. Alekhine broke the world blindfold chess record in 1924, 1925, and 1933. Among his books is *My Best Games of Chess 1908–1923* (1927).

Aleksandar (Serbo-Croatian personal name): see under Alexander.

Aleksander (Polish personal name): see under Alexander.

Aleksandr (Russian personal name): see under Alexander.

Aleksandravičius, Jonas (Lithuanian poet): see Aistis, Jonas.

Aleksandriya, also spelled ALEKSANDRIJA, or ALEKSANDRIIA, city, Kirovograd oblast (province), Ukraine, on the Ingulets River. Founded as Usovka in 1754, it was incorporated and renamed in the same year. The city is now the centre of a lignite (brown coal) field that has been utilized since the 1950s to power local rayon fibre engineering and other plants. Pop. (1998 est.) 101,000.

Aleksandrovsk (city, Ukraine): see Zaporozhye.

Aleksandrovsk-Grushevsky (city, Russia): see Shakhty.

Aleksandrovsk-Sakhalinsky, city, Sakhalin oblast (province), far-eastern Russia, on the western coast of Sakhalin Island. It was founded in 1881 as a centre for penal settlements. In 1890 the writer Anton Chekhov lived there while gathering material about convict life for his book *Ostrov Sakhalin* ("Sakhalin Island"). It became a city in 1926 and from 1932 to 1947 was the centre of an oblast. Pop. (1991 est.) 19,600.

Aleksandŭr (Bulgarian personal name): see under Alexander.

Aleksey, also spelled ALEKSEI (Russian personal name): *see under* Alexis.

Alekseyev, Konstanin Sergeyeovich (theatre director): *see* Stanislavsky, Konstantin (Sergeyeovich).

INDEX
first

Alekseyev, Mikhail Vasilyevich, Alekseyev also spelled ALEKSEEV (b. Nov. 15 [Nov. 3, old style], 1857, Tver, Russia—d. Oct. 8, 1918, Yekaterinodar), commander in chief of the Russian Army for two months in World War I and a military and political leader of the White (anti-Bolshevik) forces in the Russian Civil War that followed the Russian Revolution of October 1917.

The son of a private soldier, Alekseyev entered the Russian Army in 1876 and was graduated in 1890 from the staff college. He became a general in 1904. Early in World War I, he planned the successful Russian offensive into Galicia. After a period of command on the northwestern front, he became chief of the general staff (August 1915) and assumed control of all Russian armies in the European theatre.

Alekseyev was handicapped by the growing divergence of Russian public opinion and the wishes of the imperial court. In the fall of 1916 his intention to present the emperor Nicholas II with a peremptory demand for reform became known, and Alekseyev was suspended from duty. In March 1917 when Nicholas abdicated, Alekseyev was appointed commander in chief. He resigned, however, on May 21 in protest against the provisional government's failure to suppress defeatism and anarchy in the army.

Subsequently, Alekseyev tried to arrange a compromise between the conservative Gen. L.G. Kornilov and Aleksandr F. Kerensky, who became prime minister in the Provisional Government (July–October 1917). After the revolution, Alekseyev organized the anti-Bolshevik force (the White Army) in the region of the Don.

Alekseyev, Vasily Ivanovich (b. Jan. 7, 1942, Pokrovo-Shishkino, Russian S.F.S.R.), Soviet super-heavyweight weightlifter (over 110-kilogram [242½-pound] class) who between 1970 and 1978 set 79 world records.

Alekseyev was the son of a lumberjack; at the age of 12 he was felling trees alongside the men and at the age of 14 was wrestling them on even terms. He was enrolled in a forestry institute in 1961 and was graduated from Novochoerkassk Polytechnical Institute in 1971. He was a member of the Communist Party from 1975 and was awarded the Order of Lenin. He became a mining engineer by profession.

Alekseyev began weightlifting competition in 1961, took third place in the 1968 U.S.S.R. meet, and won in 1970. He held this championship through 1976. He was also world champion (1970–71; 1973–75; 1977) and European champion (1970–75; 1977–78). He broke four world records in 1970, including a three-lift record of 200 kg (total 1,323 lb) that he later raised to 231.78 kg. In the 1972 Olympic Games at Munich and the 1976 Olympic Games at Montreal, he won the gold medal in his division. In the 1978 world championship, he withdrew from competition because of an injury, and in the 1980 Olympic Games at Moscow, he did not qualify for the finals. Thereafter he retired from competition.

Alekseyevsk (Russia): *see* Svobodny.

Aleksin, city, Tula *oblast* (province), western Russia, on the Oka River, 40 miles (65 km)

northwest of Tula city. Aleksin, first documented in 1236, was at first a fortress, then a river port. The decline of river trade adversely affected the city, but since the October Revolution (1917) it has become a significant industrial centre, with engineering and building-materials industries. Pop. (1991 est.) 74,200.

Alemán, Mateo (baptized Sept. 28, 1547, Seville—d. c. 1614, Mexico), novelist, a master stylist best known for his early, highly popular picaresque novel, *Guzmán de Alfarache*.

Descended from Jews who had been forcibly converted to Catholicism, Alemán expressed many aspects of the experiences and feelings of the New Christians in 16th-century Spain. His most important literary work, *Guzmán de Alfarache* (1599; a second part, 1604; Eng. trans., *The Spanish Rogue*, 1622, 1924), which brought him fame throughout Europe but little profit, is one of the earliest picaresque novels. The first part ran through many editions, almost all pirated; even before he could finish the second part, a spurious sequel had appeared. Alemán's life, in many ways like that of his protagonist, Guzmán, was afflicted with severe economic and personal reverses. He was the son of a prison doctor and studied medicine at Salamanca and Alcalá for four years after graduating from the University of Seville in 1564, but he never practiced. In 1580 he was imprisoned for debt. Only after he emigrated to Mexico in 1608 did his fortunes become settled and his life stable.

Alemán, Miguel (b. Sept. 29, 1902, Sayula, Mex.—d. May 14, 1983, Mexico City), president of Mexico from 1946 to 1952.

The son of a village shopkeeper who subsequently became a general in the revolution, Alemán studied law and set up practice in Mexico City, specializing in labour cases. Appointed senator from Veracruz, he became governor of the state in 1936. In 1940 he resigned to manage the successful presidential

Miguel Alemán, c. 1951

By courtesy of the Organization of American States

campaign of Manuel Ávila Camacho, who rewarded him with the powerful post of minister of *gobernación* ("interior"). Alemán became the official candidate for the presidency on the ticket of the Partido Revolucionario Institucional (Revolutionary Institutional Party) in 1946 and easily defeated Ezequiel Padilla. His administration saw a slowdown in Mexico's agrarian reform but greatly accelerated industrial development. Although his regime was charged with extensive graft and corruption, economic progress was marked during his tenure. From the early 1960s he served as president of a national tourist council, a position he held until his death.

Alemanni, also spelled ALAMANNI, or ALAMANI, a Germanic people first mentioned in connection with the Roman attack on them in AD 213. In the following decades, their pressure on the Roman provinces became severe; they occupied the Agri Decumates c. 260, and late in the 5th century they expanded into Alsace and northern Switzerland, establishing the German language in those regions. In 496

they were conquered by Clovis and incorporated into his Frankish dominions.

The Alemanni were originally composed of fragments of several Germanic peoples, and they remained a loosely knit confederation of tribes in the Suebi group (*see* Suebi). Although several tribes put their military forces under the joint command of two leaders for the duration of a campaign, the different peoples generally found it difficult to combine, and they had nothing that could be called a central government. The French and Spanish words for Germany (Allemagne; Alemania) are derived from their name.

Alembert, Jean Le Rond d' (b. Nov. 17, 1717, Paris—d. Oct. 29, 1783, Paris), French mathematician, philosopher, and writer, who achieved fame as a mathematician and scientist before acquiring a considerable reputation

D'Alembert, pastel by Maurice-Quentin de La Tour

By courtesy of the Bibliothèque Nationale, Paris

as a contributor to and editor of the famous *Encyclopédie*.

Early life. The illegitimate son of a famous hostess, Mme de Tencin, and one of her lovers, the chevalier Destouches-Canon, d'Alembert was abandoned on the steps of the Parisian church of Saint-Jean-le-Rond, from which he derived his Christian names. Although Mme de Tencin never recognized her son, Destouches eventually sought out the child and entrusted him to a glazier's wife, whom d'Alembert always treated as his mother. Through his father's influence, he was admitted to a prestigious Jansenist school, enrolling first as Jean-Baptiste Dairemberg and subsequently changing his name, perhaps for reasons of euphony, to d'Alembert. Although Destouches never disclosed his identity as father of the child, he left his son an annuity of 1,200 livres. D'Alembert's teachers at first hoped to train him for theology, being perhaps encouraged by a commentary he wrote on St. Paul's Letter to the Romans, but they inspired in him only a lifelong aversion to the subject. He spent two years studying law and became an advocate in 1738, although he never practiced. After taking up medicine for a year, he finally devoted himself to mathematics—"the only occupation," he said later, "which really interested me." Apart from some private lessons, d'Alembert was almost entirely self-taught.

Mathematics. In 1739 he read his first paper to the Academy of Sciences, of which he became a member in 1741. In 1743, at the age of 26, he published his important *Traité de dynamique*, a fundamental treatise on dynamics containing the famous "d'Alembert's principle," which states that Newton's third law of motion (for every action there is an equal and opposite reaction) is true for bodies that are free to move as well as for bodies rigidly fixed. Other mathematical works followed very rapidly; in 1744 he applied his

principle to the theory of equilibrium and motion of fluids, in his *Traité de l'équilibre et du mouvement des fluides*. This discovery was followed by the development of partial differential equations, a branch of the theory of calculus, the first papers on which were published in his *Réflexions sur la cause générale des vents* (1747). It won him a prize at the Berlin Academy, to which he was elected the same year. In 1747 he applied his new calculus to the problem of vibrating strings, in his *Recherches sur les cordes vibrantes*; in 1749 he furnished a method of applying his principles to the motion of any body of a given shape; and in 1749 he found an explanation of the precession of the equinoxes (a gradual change in the position of the Earth's orbit), determined its characteristics, and explained the phenomenon of the nutation (nodding) of the Earth's axis, in *Recherches sur la précession des équinoxes et sur la nutation de l'axe de la terre*. In 1752 he published *Essai d'une nouvelle théorie de la résistance des fluides*, an essay containing various original ideas and new observations. In it he considered air as an incompressible elastic fluid composed of small particles and, carrying over from the principles of solid body mechanics the view that resistance is related to loss of momentum on impact of moving bodies, he produced the surprising result that the resistance of the particles was zero. D'Alembert was himself dissatisfied with the result; the conclusion is known as "d'Alembert's paradox" and is not accepted by modern physicists. In the *Memoirs* of the Berlin Academy he published findings of his research on integral calculus—which devises relationships of variables by means of rates of change of their numerical value—a branch of mathematical science that is greatly indebted to him. In his *Recherches sur différents points importants du système du monde* (1754–56) he perfected the solution of the problem of the perturbations (variations of orbit) of the planets that he had presented to the academy some years before. From 1761 to 1780 he published eight volumes of his *Opuscules mathématiques*.

The Encyclopédie. Meanwhile, d'Alembert began an active social life and frequented well-known salons, where he acquired a considerable reputation as a witty conversationalist and mimic. Like his fellow Philosophes—those thinkers, writers, and scientists who believed in the sovereignty of reason and nature (as opposed to authority and revelation) and rebelled against old dogmas and institutions—he turned to the improvement of society. A rationalist thinker in the free-thinking tradition, he opposed religion and stood for tolerance and free discussion; in politics the Philosophes sought a liberal monarchy with an "enlightened" king who would supplant the old aristocracy with a new, intellectual aristocracy. Believing in man's need to rely on his own powers, they promulgated a new social morality to replace Christian ethics. Science, the only real source of knowledge, had to be popularized for the benefit of the people, and it was in this tradition that he became associated with the *Encyclopédie* about 1746. When the original idea of a translation into French of Ephraim Chambers' English *Cyclopaedia* was replaced by that of a new work under the general editorship of the philosophe Denis Diderot, d'Alembert was made editor of the mathematical and scientific articles. In fact, he not only helped with the general editorship and contributed articles on other subjects but also tried to secure support for the enterprise in influential circles. He wrote the *Discours préliminaire* that introduced the first volume of the work in 1751. This was a remarkable attempt to present a unified view of contemporary knowledge, tracing the development

and interrelationship of its various branches and showing how they formed coherent parts of a single structure; the second section of the *Discours* was devoted to the intellectual history of Europe from the time of the Renaissance. In 1752 d'Alembert wrote a preface to Volume III, which was a vigorous rejoinder to the *Encyclopédie's* critics, while an *Éloge de Montesquieu*, which served as the preface to Volume V (1755), skillfully but somewhat disingenuously presented Montesquieu as one of the *Encyclopédie's* supporters. Montesquieu had, in fact, refused an invitation to write the articles "Democracy" and "Despotism," and the promised article on "Taste" remained unfinished at his death in 1755.

In 1756 d'Alembert went to stay with Voltaire at Geneva, where he also collected information for an *Encyclopédie* article, "Genève," which praised the doctrines and practices of the Genevan pastors. When it appeared in 1757, it aroused angry protests in Geneva because it affirmed that many of the ministers no longer believed in Christ's divinity and also advocated (probably at Voltaire's instigation) the establishment of a theatre. This article prompted Rousseau, who had contributed the articles on music to the *Encyclopédie*, to argue in his *Lettre à d'Alembert sur les spectacles* (1758) that the theatre is invariably a corrupting influence. D'Alembert himself replied with an incisive but not unfriendly *Lettre à J.-J. Rousseau, citoyen de Genève*. Gradually discouraged by the growing difficulties of the enterprise, d'Alembert gave up his share of the editorship at the beginning of 1758, thereafter limiting his commitment to the production of mathematical and scientific articles.

Later literary, scientific, and philosophical work. His earlier literary and philosophical activity, however, led to the publication of his *Mélanges de littérature, d'histoire et de philosophie* (1753). This work contained the impressive *Essai sur les gens de lettres*, which exhorted writers to pursue "liberty, truth and poverty" and also urged aristocratic patrons to respect the talents and independence of such writers.

Largely as a result of the persistent campaigning of Mme du Deffand, a prominent hostess to writers and scientists, d'Alembert was elected to the French Academy in 1754; he proved himself to be a zealous member, working hard to enhance the dignity of the institution in the eyes of the public and striving steadfastly for the election of members sympathetic to the cause of the Philosophes. His personal position became even more influential in 1772 when he was made permanent secretary. One of his functions was the continuation of the *Histoire des membres de l'Académie*; this involved writing the biographies of all the members who had died between 1700 and 1772. He paid tribute to his predecessors by means of *Éloges* that were delivered at public sessions of the academy. Though of limited literary value, they throw interesting light on his attitude toward many contemporary problems and also reveal his desire to establish a link between the Academy and the public.

From 1752 onward, Frederick II of Prussia repeatedly tried to persuade d'Alembert to become president of the Berlin Academy, but the philosopher contented himself with a brief visit to the King at the Rhine village of Wesel in 1755 and a longer stay at Potsdam in 1763. For many years he gave the King advice on the running of the academy and the appointment of new members. In 1762 another monarch, the empress Catherine II of Russia, invited d'Alembert to become tutor to her son, the grand duke Paul; this offer also was refused. Apart from fearing the harmful effects of foreign residence upon his health and personal position, d'Alembert did not wish to be separated from the intellectual life of Paris.

Although as a skeptic, d'Alembert willingly

supported the Philosophes' hostility to Christianity, he was too cautious to become openly aggressive. The expulsion of the Jesuits from France, however, prompted him to publish "by a disinterested author," at first anonymously, and then in his own name, *Sur la destruction des Jésuites en France* (1765; *An Account of the Destruction of the Jesuits in France*, 1766). He there tried to show that the Jesuits, in spite of their qualities as scholars and educators, had destroyed themselves through their inordinate love of power.

During these years d'Alembert's interests included musical theory. His *Éléments de musique* of 1752 was an attempt to expound the principles of the composer Jean-Philippe Rameau (1683–1764), who had consolidated contemporary musical development into a harmonic system that dominated Western music until about 1900. In 1754 d'Alembert published an essay expressing his thoughts on music in general—and French music in particular—entitled *Réflexions sur la musique en général et sur la musique française en particulier*. He also published in his mathematical *opuscules* treatises on acoustics, the physics of sound, and he contributed several articles on music to the *Encyclopédie*. In 1765 a serious illness compelled him to leave his foster-mother's house, and he eventually went to live in the house of Julie de Lespinasse, with whom he fell in love. He was the leading intellectual figure in her salon, which became an important recruiting centre for the French Academy. Although they may have been intimate for a short time, d'Alembert soon had to be satisfied with the role of steadfast friend. He discovered the extent of her passionate involvement with other men only after Julie's death in 1776. He transferred his home to an apartment at the Louvre—to which he was entitled as secretary to the Academy—where he died.

Assessment. Posterity has not confirmed the judgment of those contemporaries who placed d'Alembert's reputation next to Voltaire's. In spite of his original contributions to the mathematical sciences, intellectual timidity prevented his literary and philosophical work from attaining true greatness. Nevertheless, his scientific background enabled him to elaborate a philosophy of science that, inspired by the rationalist ideal of the ultimate unity of all knowledge, established "principles" making possible the interconnection of the various branches of science. Moreover, d'Alembert was a typical 18th-century Philosophe, for in both his life and his work he tried to invest the name with dignity and serious meaning. In his personal life he was simple and frugal, never seeking wealth and dispensing charity whenever possible, always watchful of his integrity and independence, and constantly using his influence, both at home and abroad, to encourage the advance of "enlightenment."

(R.Gr.)

BIBLIOGRAPHY. The main editions of d'Alembert's collected works are: *Oeuvres philosophiques, historiques et littéraires de d'Alembert*, ed. by J.F. Bastien, 18 vol. (1805); and *Oeuvres complètes de d'Alembert*, ed. by Bossange and Belin, 5 vol. (1821, reprinted 1967). These may be supplemented by d'Alembert's *Mélanges de littérature, d'histoire et de philosophie*, 2 vol. (1753), 4 vol. (1759), 5th vol. (1767), which contain a few pieces omitted from the collected editions; and his *Histoire des membres de l'Académie française morts depuis 1700 jusqu'en 1771*, 6 vol. (1785–87, reprinted 1970). General studies are: Joseph Bertrand, *D'Alembert* (1889); and Ronald Grimsley, *Jean d'Alembert, 1717–83* (1963).

Alencar, José (Martiniano) de (b. May 1, 1829, Mecejana, Braz.—d. Dec. 12, 1877, Rio de Janeiro), journalist, novelist, and playwright whose novel *O Guarani* (1857; "The Guarani Indian") initiated the vogue of the Brazilian Indianista novel (romantic tales of indigenous life incorporating vocabulary of Amerindian origin referring to flora, fauna,

and tribal customs). *O Guarani*, which was subsequently utilized as the libretto for an opera in Italian by the Brazilian composer Carlos Gomes, depicts the platonic love affair of Peri, a noble savage, and Ceci, the white daughter of a wealthy landowner.

Alencar's next most popular novel, *Iracema* (1865), deals with the love of a beautiful Indian maiden for a Portuguese soldier. In *O Gaúcho* (1870; "The Gaucho") and *O Sertanejo* (1876; "The Backlander"), Alencar treats life in Brazil's frontier lands. In novels such as *Luciola* (1862), *Diva* (1864), and *Senhora* (1875), he laid the foundation for Brazilian psychological fiction. Alencar, who is considered the father of Brazilian fictional writing, also cultivated the historical novel in such works as *As Minas de Prata* (1862; "The Silver Mines"). His abolitionist stance is revealed in several plays, including *Mãe* (1860; "Mother").

Alencar also was a lawyer, a deputy in the legislature, and minister of justice (1868–70).

Alençon, town, Orne *département*, Basse-Normandie *région*, northwestern France. Alençon lies at the juncture of the Sarthe and Briante rivers, in the centre of a plain ringed by wooded hills. It is known for its tulle and lace (especially *point d'Alençon*), introduced from Venice in the mid-17th century. Incorporated in the duchy of Normandy in 911, it was capital of the county and duchy of Alençon and passed to the French crown in 1549. Parts of its castle, taken by William of Normandy in 1048, remain; law courts have been built into the castle's living quarters. The town's Church of Notre-Dame dates mostly from the 15th–17th century. The medieval Maison d'Ozé and the 18th-century town hall survived heavy bombardments in 1944. Recent industrial development includes printing and light manufacturing. Pop. (1990) 31,139.

Alençon, (Hercule-) François, duc d' (duke of): see Anjou, (Hercule-) François, duc d'.

Alençon lace, FRENCH POINT D'ALENÇON, needle lace made in the French city of Alençon, one of the centres designated by Jean-Baptiste Colbert, minister of finance under Louis XIV, for aid in his effort to make French laces financially and artistically competitive with imported laces. Venetian workers, experts in making *point de Venise*, were brought in to instruct the local needlewomen, who quickly learned the technique and, by the end of the Royal Monopoly (see *point de France*), were evolving a distinctive lace. Alençon lace is characterized by a cordonnet usually made over horsehair, a firm needle mesh of double twisted threads, and many and varied filling stitches within floral and scroll patterns.

Alentejo, also spelled ALEMTEJO, historical province of south-central Portugal. It lies southeast of the Tagus (Tejo) River and is bounded on the east by the Spanish frontier and on the southwest by the Atlantic Ocean. It is an almost featureless tableland of less than 650 feet (200 m) in elevation in the south and southwest that ascends to higher elevations in the far south and northeast. Although Alentejo is one of the driest regions in Portugal, irrigation projects make possible the cultivation of wheat, rye, oats, barley, and sugar beets. The Alentejo region produces two-thirds of the world's output of cork. Cork oak acorns are used locally for pig feed. Some livestock are pastured, and wool textiles, rugs (from Persian designs), and olive oil are manufactured there. The region's quarries yield granite, limestone, basalt, marble, and alabaster; copper and sulfur are mined.

Until the revolution of 1974, Alentejo contained estates of up to 1,000 acres (400 hectares), mostly owned by absentee landlords. A part of the forests and cropland has since been divided among the Alentejanos, usually in the form of cooperatives. Contemporary

Stripped cork oak trees in the Alentejo area, Portugal
Josef Muench

Alentejo comprises all of Beja and Évora *distritos* and most of Setúbal and Portalegre *distritos*.

'alenu (Hebrew: "it is our duty"), the opening word of an extremely old Jewish prayer, which has been recited at the end of the three periods of daily prayer since the European Middle Ages. The first section of the *'alenu* is a prayer of thanks for having set Israel apart for the service of God; the second section, omitted by those who follow the Sephardic (Spanish) rite, expresses a hope for the coming of the messianic age, when "the world will be perfected under the kingdom of the Almighty." The *'alenu* ends with the phrase: "And the Lord will become king over all the Earth; on that day the Lord will be one and his name one" (Zechariah 14:9).

Though ancient tradition ascribes the *'alenu* to Joshua, it is often credited to Abba Arika, also known as Rav (3rd century AD), the head of a Jewish academy at Sura in Babylonia. The *'alenu* was originally part of the additional (*musaf*) service for Rosh Hashana (New Year) and was later added to the Yom Kippur (Day of Atonement) liturgy. On the High Holy Days it is included in the *'amida*, the main section of the daily prayers, and is repeated in full by the cantor. The version used in the Ashkenazi (German) ritual was censored by Christian church authorities, who interpreted a sentence as a slighting reference to Jesus and so ordered its deletion. Reform Judaism uses a modified form of the *'alenu* that is called Adoration in the ritual. In *Gates of Prayer: The New Union Prayer Book* (1975), however, Reform worshipers were given the option of using the original concept of the *'alenu* in their liturgy.

Aleppo, Arabic HALAB, Turkish HALEP, principal city of northern Syria, and the second largest city of the country (after Damascus). It is situated in the northwestern part of Syria at a point about 30 miles (48 km) south of the Turkish border. Aleppo is located at the crossroads of great commercial routes and lies about 60 miles (100 km) distant from both the Mediterranean Sea (west) and the Euphrates River (east).

The city's Arabic name, Halab, is of ancient Semitic origin and is first mentioned in texts at the end of the 3rd millennium BC. In the 18th century BC Halab was the capital of the Amorite kingdom of Yamkhad, and it subsequently came under Hittite, Egyptian, Mitannian, and again Hittite rule during the 17th–14th century. In succeeding centuries it achieved some independence as a Hittite principality. It was conquered by the Assyrians in the 8th century BC, was controlled by the Achaemenian Persians from the 6th to the 4th century BC, and then fell into the hands of the Seleucids, who rebuilt it and renamed it Beroea. It became a first-ranking city of the Hellenistic period and a great commercial entrepôt between the Mediterranean region and the lands farther east. The city was absorbed

into the Roman province of Syria in the 1st century BC. It prospered under Byzantine rule but was pillaged and burned by the Persian Sāsānian king Khosrow I in AD 540. In 637 the city was conquered by the Arabs, under whom it reverted to its old name, Halab.

In the 10th century the Hamdānid dynasty established itself in Aleppo as an independent principality, and the city had a brilliant cultural life under their rule. In the 12th century Aleppo became a centre of Muslim resistance to the crusaders, who besieged it unsuccessfully in 1124–25. In 1260 Aleppo was taken by the Mongols, who massacred its inhabitants. After an interval of several centuries under the Mamlūks, the city was incorporated into the empire of the Ottoman Turks in 1516, under whom it underwent a remarkable commercial revival, becoming the principal market in the Levant. Its prosperity continued until the end of the 18th century, and full economic recovery came in 1880 with the arrival of the railroad. In the 20th century the city became an industrial centre rivaling Damascus.

The old section of Aleppo is built around a 12th-century-AD citadel that rests on a partly man-made mound dominating the city. The

Courtyard of the Zakariyah Mosque, Aleppo, Syria, with the citadel in the background
Sam Abboud—FPG

old section has the most famous covered bazaars in the Middle East, extending for many miles through narrow streets. Its many khans (caravan rest houses), mosques, and merchants' houses are built of limestone, with many dating from the 16th and 17th centuries. Another point of interest is the Great, or Zakariyah, Mosque (built AD 715, rebuilt 1258), which is named after Zacharias, the father of John the Baptist. Parts of the city's old stone walls, along with several of their gates, are still intact.

Aleppo's main industries are silk weaving, cotton printing, the manufacture of soaps and dyes, and the preparation of hides, wool, dried fruit, and nuts. Aleppo is also an intellectual centre with a university, an institute of music, and several Muslim madrasahs, or theological schools. The National Museum displays ancient artifacts found in northern Syria at several major archaeological sites.

Aleppo lies along the Istanbul-Baghdad railway and is linked by rail with Damascus and Beirut (Lebanon) as well. It has road connections to Damascus, Latakia, and Antioch (Turkey), along with an airport. The surrounding agricultural area produces wheat, cotton, barley, vegetables, fruit, nuts, and sesame. Pop. (1989 est.) 1,308,000.

aleppo boil (infection): see Oriental sore.

alerce, also called PATAGONIAN CYPRESS (species *Fitzroya cupressoides*), coniferous tree that is the only species of the genus *Fitzroya*, of the cypress family (Cupressaceae), native to southern Chile and southern Argentina. In the wild it grows to become one of the oldest and largest trees in the world. The alerce is

thought to be a southern relative of the giant sequoia of North America. The oldest known alerce is believed to be about 4,000 years old. The alerce is often shrubby when raised in cultivation, but a native forest tree may reach a height of 45 m (about 150 feet) and attain a trunk diameter of more than 3 m (10 feet). The alerce's small, narrow leaves are typically arranged in whorls of three and have distinct white bands running down their length. The tree's reddish brown wood is lightweight and durable and is used for general construction.

Aleric (antipope): see *Albert under Albert* (Papacy).

Alès, town, Gard *département*, Languedoc-Roussillon *région*, southeastern France. It lies along a bend of the Gardon d'Alès River, at the foot of the Cévennes mountains, north-northwest of Nîmes. The town's name meant "industry" in the language of its 10th-century-BC Phoenician founders. Alestium was its Roman name, and until 1926 the French called it Alais. Chartered in 1200, it became part of the kingdom of France in 1243. The Peace of Alais (1629) ended the French Wars of Religion, in which the town was seriously damaged. Completed in 1788, a fort designed by Sébastien Le Prestre de Vauban, the celebrated military engineer, is now a museum and library. Although Alès was traditionally an area of textile production, coal mining and metallurgy became the basis for industrial development in the town. Since the 1960s, however, these activities have been in decline (accompanied by a loss of population), prompting the restructuring of the local economy. New industries, such as mechanical engineering, were introduced; central areas of the town were refurbished; and attempts were made to develop tourism. Pop. (1999) 39,346.

Alessandri Palma, Arturo (b. Dec. 20, 1868, Longavi, Chile—d. Aug. 24, 1950, Santiago), Chilean president (1920–25, 1932–38) who early defended workers' groups, especially the nitrate miners of the north, but later became more conservative.

The son of an Italian immigrant, Alessandri was graduated in law from the University of Chile in 1893 and in 1897 was elected to the

Alessandri Palma

By courtesy of the Organization of American States

Chamber of Deputies. He was at various times minister of industry, minister of finance, congressman (six times), senator (twice), and president.

Elected president in 1920 as the candidate of a liberal coalition, he was forced into exile by a military junta on Sept. 15, 1924, but was recalled, returning on March 20, 1925, on condition that the constitution be rewritten to give the president greater power. He became president again in 1932, but as a strict constitutionalist, depending primarily for support on the political right. Although he promoted economic recovery from the depression caused by decreased world demands for Chilean nitrates and copper, he had by then alienated most of

his labour and middle-class support, who joined the Popular Front. When elected to the Senate in 1946, Alessandri again displayed liberal leanings.

Alessandria, city, capital of Alessandria *provincia*, in the Piemonte (Piedmont) *regione* of northwestern Italy. The city lies at the confluence of the Bormida and Tanaro rivers, southeast of Turin (Torino). It was founded in 1168 by the towns of the Lombard League as an Alpine-valley stronghold against the Holy Roman emperor Frederick I Barbarossa. The town was first called Civitas Nova, and then Cesaria, until it was renamed for Pope Alexander III; it became a bishopric in 1175. The town was later ceded to the emperor, then transferred to the Milanese Visconti family in the 14th century, and passed formally to the house of Savoy in 1713. From 1796 to 1814 it was the capital of the French *département* of Marengo, named for the site of Napoleon's victory outside the city in 1800. Alessandria was a centre of the early 19th-century freedom movement in Piedmont, including the conspiracy of Giuseppe Mazzini in 1833. A strategic stronghold, it was garrisoned by the Austrians after their victory at Novara (1849). The city's expansion beyond its 19th-century defense works is of comparatively recent date. Notable landmarks include the cathedral, the Romanesque-Gothic Church of Santa Maria di Castello (rebuilt 14th–15th century), the 15th-century episcopal palace and other palaces of the 15th–19th century, the town hall (1826), the civic museum, and the picture gallery.

An important rail and road junction, Alessandria is also noted for hat making (notably the Borsalino). It is an important agricultural and wine market. Pop. (2002 est.) 85,430.

Alessandro, in full ALESSANDRO DE' MEDICI (b. 1510/11, Florence [Italy]—d. Jan. 5–6, 1537, Florence), the first duke of Florence (1532–37).

Alessandro was an illegitimate child, whose paternity is ascribed either to Lorenzo de' Medici (1492–1519), Duke di Urbino, or, with more likelihood, to Cardinal Giulio, nephew of Lorenzo the Magnificent. Cardinal Giulio received the lordship of Florence in 1519; but, upon being elected pope (Clement VII) in 1523, he made Silvio, Cardinal Passerini, regent in Florence for Alessandro and another bastard heir, Ippolito de' Medici. Alessandro had meanwhile been created Duke di Penna by the Holy Roman emperor Charles V (1522).

Republican sentiments and Savonarolan ideas were still strong in Florence, and Cardinal Passerini's regency was unpopular. When imperial forces sacked Rome (May 1527), revolution broke out in Florence, and Passerini and the bastards fled. The Piagnoni family then came to power in Florence and restored the old regime of the republic. The indignation of the pope counted for little so long as he was at variance with Charles V; but in June 1529 pope and emperor came to terms. Charles agreed to restore the Medici in Florence and sent an army against the city, which capitulated after a siege of 11 months (October 1529–August 1530). Reprisals were taken against the opponents of the Medici; and Alessandro, whom Charles had nominated head of state for Florence in October 1530, returned in June 1531. Ippolito had been created cardinal (January 1529).

The new Florentine constitution of April 1532 declared Alessandro to be hereditary duke and perpetual gonfalonier of the republic. Though his common sense and his feeling for justice won his subjects' affection, Alessandro was rough and uncultured, a lover of sensual pleasures who enriched himself personally through taxes and duties and was determined to make his authority absolute beyond all question. After Clement VII's death (1534) the exiled opposition sought to oust the duke from Florence and persuaded Cardinal Ippolito to

submit its case to Charles V. Ippolito, however, died suddenly at Itri (Aug. 10, 1535), on his way from Rome to Tunis, where Charles then was; and Charles, returning from Tunis, received Alessandro at Naples and decided to uphold him. Married in 1536 to the emperor's natural daughter Margaret, the duke now felt altogether secure; but in the night of Jan. 5–6, 1537, his distant cousin Lorenzino, or Lorenzaccio, de' Medici (1514–48), the companion and procurer of his licentious amusements, took advantage of his confidence in order to murder him. Disappointed at the Florentines' failure to rise against tyrannical government, Lorenzino fled and was himself murdered in 1548.

Ålesund, fishing port, Møre og Romsdal *fylke* (county), western Norway. Ålesund lies at the mouth of Stor Fjord and is set on two islands,

Ålesund, at the mouth of Stor Fjord, Norway

Mittel Foto A/S

Nørøya and Aspøy, which are connected by bridges. It dates from the 9th century when Rollo (Rolf) the Ganger built a castle nearby, but township status was not acquired until 1848. After the town burned in 1904, it was rebuilt with stone instead of wood. Ålesund is a regional commercial centre and a point for touring the hills of the Sunnmøre region, the Norang valley, the Øye glaciers, the island of Runde, and the Viking village of Giske. The site of Norway's largest fishing harbour, it is a base for cod and halibut fishing trawlers and the headquarters of the Arctic sealing fleet. Milk and fruit are produced locally. Pop. (2003 est.) mun., 39,695.

Aleut, a native of the Aleutian Islands and western portion of the Alaska Peninsula of northwest North America. Aleuts speak two main mutually intelligible dialects and are closely related to the Eskimo in language and culture. The earliest people, the Paleo-Aleuts, arrived in the Aleutian Islands from the Alaskan mainland about 2000 BC.

The Aleuts hunted seals, sea otters, whales, sea lions, sometimes walrus, and, in some areas, caribou and bears. Fish, birds, and mollusks were also taken. One-man and two-man skin boats known as bidarkas, or kayaks, and large, open, skin boats (Eskimo umiaks) were used. Aleut women wove fine grass basketry; stone, bone, and ivory were also worked.

Ancient Aleut villages were situated on the seashore near fresh water, with a good landing for boats and in a position safe from surprise attack from other Aleuts or neighbouring groups. After the arrival of the Russians in the 18th and 19th centuries, internal warfare ceased, and villages were located at river mouths, where salmon were caught in the annual salmon runs. Villages were usually composed of related families. A chief might govern several villages or an island.

The Aleut population declined drastically under Russian domination. When the Russians first arrived, there were about 25,000

Aleuts, but by the end of the 20th century they numbered only about 2,000. By the 1830s their traditional way of life was disrupted, and only vestiges have survived.

Aleut-Eskimo languages: see Eskimo-Aleut languages.

Aleut language, Aleut UNANGAM TUNUU, one of two branches of the Eskimo-Aleut languages (*q.v.*). Two mutually intelligible dialects survive, Eastern Aleut and Atkan Aleut. A third dialect, Attu, now extinct in Alaska, survives on Bering Island (one of the Komandor Islands) in a creolized form that incorporates Russian verbal inflections. Aleut is spoken from the Alaska Peninsula through Umnak Island and on Atka Island in the Aleutian Islands, on the Pribilof Islands north of the Aleutians, and on Bering Island.

Aleutian Basin, submarine depression forming the floor of the southwestern section of the Bering Sea in the Pacific Ocean. On the west it rises to meet Siberia and the Kamchatka Peninsula; on the northeast, the continental shelf of North America off southwestern Alaska; and on the south, the Aleutian Islands. The basin extends about 1,100 miles (1,800 km) north-south and 600 miles (1,000 km) east-west and is over 9,800 feet (3,000 m) deep. Its floor has a thick basaltic crust. The volcanic Aleutian Arc separates the basin from the floor of the North Pacific Ocean.

Aleutian Islands, chain of small islands that separate the Bering Sea (north) from the main portion of the Pacific Ocean (south) and extend in an arc southwest, then northwest, for about 1,100 miles (1,800 km) from the tip of the Alaska Peninsula to Attu Island, Alaska, U.S. The archipelago consists of 14 large islands, some 55 smaller islands, and innumerable islets, all of which occupy a land area of

Sweeper Cove of Adak Island, one of the Aleutian Islands, Alaska

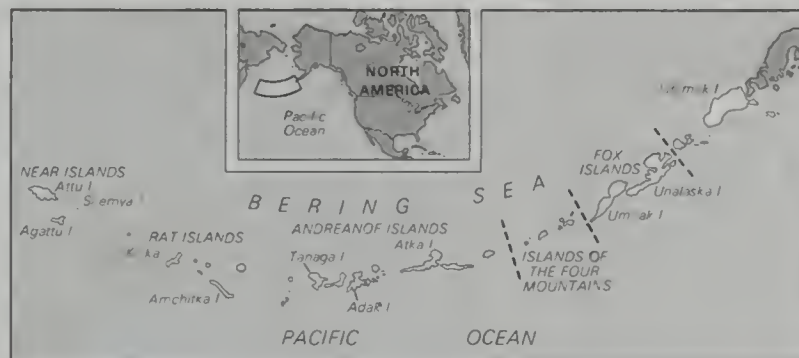

Bob and Ira Spring

6,821 square miles (17,666 square km) and are part of the U.S. state of Alaska. The major island groups from east to west are the Fox Islands, the Islands of the Four Mountains, and the Andreanof, Rat, and Near islands. The Komandor (Commander) Islands near the Kamchatka Peninsula (Russia) are geographically part of the Aleutians.

The Aleutian Islands form a segment of the Circum-Pacific chain of volcanoes (often called the Ring of Fire) and represent a partially submerged continuation of Alaska's Aleutian Range. Most of the islands bear marks of volcanic origin; some volcanoes remain active. The shores are rocky and worn by the surf, and the approaches are dangerous; the land rises abruptly from the coasts to steep, bold mountains. The main navigational lanes through the chain are the Umnak, Umnak, Amukta, and Seguam passes.

Characterized by fairly uniform temperatures, high winds, heavy rainfall, and persistent fog, the Aleutians are practically devoid of trees but are covered with a luxuriant growth of grasses, sedges, and many flowering plants. The Aleutian Islands unit of the Alaska Mar-

itime National Wildlife Refuge covers 4,250 square miles (11,000 square km) and extends between Unimak (east) and Attu (west) islands. By regulating the numbers of wildlife (notably sea otters and seals), the refuge has eliminated the threat of starvation to the native Aleuts, who have always lived by fishing and hunting. The raising of blue foxes has furnished employment for many.

Aleutian Islands

The main settlements are on Unalaska and Adak islands. The oldest and largest, settled 1760–75, is Unalaska, the former headquarters of a large U.S. Coast Guard fleet that patrolled the sealing grounds of the Pribilof Islands to the north.

In 1741 the Russians sent out Vitus Bering, a Dane, and Aleksey Chirikov, a Russian, on a voyage of discovery. After their ships parted in a storm, Chirikov discovered several of the eastern islands, while Bering discovered several of the western islands. Upon learning of the abundance of fur-bearing animals, Siberian hunters flocked to the Komandor Islands and gradually moved eastward across the Aleutians to the mainland. In this manner, Russia gained a foothold in North America but nearly caused the extinction of the Aleuts as a consequence of slaughter and enslavement. Russia sold the islands, along with the rest of Alaska, to the United States in 1867.

In 1942 the Japanese invaded and occupied Attu and Kiska islands and relocated and interned the inhabitants. A year later, the United States recaptured Attu after 19 days of fighting. During the Cold War the military stations on the Aleutian Islands were vital links in the strategic defense of the North American continent. Pop. (1990) 11,942.

Aleutian Range, segment of the Pacific Coast Ranges of western North America, extending southwestward for about 600 miles (970 km) from the west end of the Alaska Range to the head of Cook Inlet of the Gulf of Alaska, U.S. The Aleutian Islands represent a southwest extension of the mountain peaks, which stretch the length of the Alaska Peninsula and include many volcanoes, notably Katmai (6,716 feet [2,047 m]) and Veniaminof. The range, named for the Aleuts who inhabited the island region, embraces Lake Clark National Park and Preserve, the Katmai National Park and Preserve (including the Valley of Ten Thousand Smokes), and the Aniakchak National Monument and Preserve.

alewife, also called SAWBELLY, GRAYBACK, GASPÉRAU, or BRANCH HERRING (*Pomolobus*,

Alewife (*Pomolobus pseudoharengus*)

Painting by Karen Allan

or *Alosa, pseudoharengus*), important North American food fish of the herring family, Clupeidae. Deeper-bodied than the true herring, the alewife has a pronounced saw-edge on the underside; it grows to about 30 cm (1 foot). Except for members of a few lake populations,

it spends several years along the Atlantic coast of North America before ascending freshwater streams (possibly the parent stream) to spawn each spring in ponds or sluggish rivers. Alewives entered the Great Lakes through the St. Lawrence Seaway and the Welland Canal. In the 1960s they multiplied so rapidly that they became a nuisance, threatening the native fishes by competing for the same food sources. Importation of coho and king salmon brought the alewife population into balance in the Great Lakes in the 1970s.

Alexander, name of rulers grouped below by country or papacy and indicated by the symbol ●.

BULGARIA

● **Alexander I** (b. April 5, 1857, Verona, Venice [Italy]—d. Nov. 17, 1893, Graz, Austria), the first prince of modern autonomous Bulgaria.

Alexander I of Bulgaria

By courtesy of the Bild-Archiv, Osterreichische Nationalbibliothek Vienna

The son of Prince Alexander of Hesse (previously created prince of Battenberg upon hismorganatic marriage) and a favourite nephew of Alexander II of Russia, Alexander served during 1877 with the Russian forces in the Russo-Turkish War (1877–78), which resulted in the autonomy of Bulgaria. In accordance with the provisions of the Congress of Berlin (1878), Alexander was elected constitutional prince of the newly autonomous Bulgarian state on April 29, 1879, but he had to deal with a strong Russian interference in domestic affairs. Saddled with what he regarded

as an absurd liberal constitution, however, he set himself to undermining the state's constitutional bases, first dissolving the national assembly (1880) and then suspending the constitution and assuming for himself plenary powers (1881). With the deterioration of his relations with Russia after the accession of Alexander III, however, he restored the constitution (1883) and accepted a new liberal-conservative coalition government to combat Russian influence.

When the annexation of Eastern Rumelia by Bulgaria (September 1885) further exacerbated Russo-Bulgarian relations, the Tsar was determined to drive Prince Alexander from his throne. In Serbia passions were also aroused, and war resulted (November 1885). Alexander successfully led Bulgarian troops against the Serbs and by late November 1885 had pushed into Serbian territory. Under Austrian pressure, however, he was forced to accept an armistice and a peace confirming the status quo (Treaty of Bucharest, March 1886), though he later won the recognition of the Great Powers for Eastern Rumelia's union with Bulgaria (April 1886). Finally, a pro-Russian officers' coup on Aug. 21, 1886, forced him to abdicate, and under heavy guard he was conducted out of the country. He returned shortly to reclaim his crown but, after failing to win the support of Russia, formally abdicated on Sept. 7, 1886. He later assumed the title Graf von Hartenau and served as a general in the Austrian Army.

BYZANTINE EMPIRE

• **Alexander** (b. 870—d. June 6, 913, Constantinople), Byzantine emperor from May 12, 912, third son of the emperor Basil I, who founded the Macedonian dynasty and caused the renewal of warfare between Bulgaria and the Byzantine Empire.

Alexander was crowned co-emperor with his brother Leo VI in 879 after the death of their elder brother, Constantine, but he remained inactive in state affairs until after Leo's death in May 912. Sending Leo VI's fourth wife, Zoe, to a nunnery, he replaced Leo's advisers and reinstated the deposed patriarch, Nicholas Mysticus. Alexander's refusal to pay the annual tribute owed to the Bulgars by the treaty of 896 precipitated war with Symeon, their powerful and aggressive king. Alexander declared his nephew, Leo's young son, later Constantine VII, his heir to the Byzantine throne and was co-regent with him for several months.

FLORENCE

• **Alexander**: see Alessandro.

GREECE

• **Alexander** (b. July 20, 1893, Athens—d. Oct. 25, 1920, Tatoi Palace, near Athens), king of Greece from 1917 to 1920.

The second son of King Constantine (ruled 1913–17 and 1920–22) and Queen Sophia, Alexander became king (June 12, 1917) when his father was forced by the Allies of World War I to abdicate and thereby allow his country to join them in the war. Shortly after Alexander's accession to the throne, Eleuthérios Venizélos became premier of Greece, dominating Alexander and the government. Venizélos made Greece a participant in the war and subsequently attained a series of diplomatic triumphs at the peace conference, gaining the territories of Smyrna and eastern and western Thrace from Turkey and Bulgaria (treaties of Sèvres and Neuilly, 1920 and 1919) and presenting Alexander with the prospect of expanding Greece's frontiers farther into Anatolia. Before Alexander was able to pursue that objective, however, he was bit-

ten by a pet monkey and died from blood poisoning.

MACEDONIA

• **Alexander I**, byname ALEXANDER PHILHELLENE, or ALEXANDER THE WEALTHY (d. c. 450 BC), 10th king of ancient Macedonia, who succeeded his father, Amyntas I, about 500 BC. More than a decade earlier, Macedonia had become a vassal state of Persia; and in 480 Alexander was obliged to accompany Xerxes I in a campaign through Greece, though he secretly aided the Greek allies. With Xerxes' apparent acquiescence, Alexander seized the Greek colony of Pydna and advanced his frontiers eastward to the Strymon, taking in Crestonia and Bisaltia, with the rich silver deposits of Mt. Dysorus.

It was probably Alexander who organized the mass of his people as a hoplite army called *pezhetairoi* ("foot companions"), with rudimentary political rights, to act as a counterweight to the nobility, the cavalry *hetairoi* ("companions"). His byname, the Philhellene, indicates his efforts to win Greek sympathies; and he obtained admission to the Olympic games. From Persian spoil he erected a golden statue at Delphi, and he entertained the poet Pindar at his court.

• **Alexander III**, byname ALEXANDER THE GREAT, or ALEXANDER OF MACEDONIA (b. 356 BC, Pella, Macedonia—d. June 13, 323, Babylon), king of Macedonia (336–323 BC), son of Philip II. One of the greatest generals in history, he overthrew the Persian empire, carried Macedonian arms to India, and laid the foundations for the Hellenistic world of territorial kingdoms. In the process he became a legendary hero.

A brief account of the life and works of Alexander III follows; for a full biography, see MACROPAEDIA: Alexander the Great.

From age 13 to 16, Alexander was taught by the philosopher Aristotle; he came to the Macedonian throne in 336, liquidated potential rivals, and consolidated his political power in Greece. In spring 334 he set off on his celebrated Persian expedition; in the winter of 334–333 he conquered western Asia Minor, and in July 332 stormed the island city of Tyre in his greatest military victory. He then consolidated his hold on the Mediterranean coast and entered and subdued Egypt (332–331). Returning to Tyre (spring 331) he advanced across Mesopotamia and occupied Babylon, city and province. In spring 330 he marched north into Media and occupied its capital, setting out in midsummer on his campaign eastward, to central Asia. Resistance of Scythians and others was strong, and not finally overcome until 328. In early summer 327 Alexander set out to invade India, crossing the Indus in spring 326. He then set about consolidating the empire thus won, dealing with conflicts between Macedonians and Persians, and attempting to solve the problem of wandering mercenaries (summer 324). He died 10 days after being taken ill after a prolonged banquet and drinking bout, and his body, diverted to Egypt, was eventually placed in a golden coffin in Alexandria.

PAPACY

• **Alexander I**, SAINT (d. c. 115/119, Rome?; feast day May 3), fifth pope after St. Peter and successor to St. Evaristus. His 10-year rule (105–115 or 109–119) is attested by Pope St. Eusebius (309/310). Some Catholic writers ascribe to him the introduction of holy water and the custom of mixing sacramental wine with water, and he may have made additions to the liturgy. It is believed he suffered martyrdom, possibly by decapitation, under the Roman emperor Trajan or Hadrian. He has sometimes been confused with St. Alexander, one of three Roman martyrs buried along the

Via Nomentana. Alexander's jailer, St. Quirinus, and his daughter St. Balbina are said to have been converted by him.

• **Alexander II**, also called (until 1061) ANSELM OF BAGGIO, or OF LUCCA, Italian ANSELMO DA BAGGIO, or DI LUCCA (b. Baggio, near Milan—d. April 21, 1075), pope from 1061 to 1073.

He studied under Lanfranc at Bec. As bishop of Lucca he worked for the abolition of simony and the enforcement of clerical celibacy. Though he was elected pope, the German court nominated Peter Cadalus of Parma as Honorius II, and Alexander was not recognized by the empire until 1064. In 1062 the antipope was dropped by the German regents, and the schism ceased to be important. In cooperation with Hildebrand (later Pope Gregory VII) and St. Peter Damian, Alexander laid the foundations of a reform movement.

• **Alexander III**, original name ROLANDO BANDINELLI (b. c. 1105, Siena, Tuscany—d. Aug. 30, 1181, Rome), pope from 1159 to 1181, a vigorous exponent of papal authority, which he defended against challenges by the Holy Roman emperor Frederick Barbarossa and Henry II of England.

Life. After studies in theology and law, Bandinelli became professor of law at Bologna and emerged as an important legal scholar and theologian. He wrote a commentary on the *Decretum Gratiani* and a book of *Sentences*, or theological opinions. He rose rapidly in the church during the pontificate of Pope Eugenius III and, during the reign of Pope Adrian IV, served as chief papal negotiator with Emperor Frederick Barbarossa.

In the complex politics of the 12th century, Bandinelli emerged as a man of keen judgment and shrewd understanding. His intellect was subtle and his instincts diplomatic. He belonged to that group of cardinals in the Roman Curia who feared the growing strength of the Holy Roman Empire in Italy and inclined toward the Norman kingdom of Sicily as a means of redressing the balance of power. He participated in the drawing up of the Concordat of Benevento (1156) between the papacy and King William I of Sicily. He revealed his fear of the empire still further in the following year at Besançon (1157), where he referred to the empire as a "benefice" of the papacy. The term aroused a storm of controversy with the imperial chancellor Rainald of Dassel, who argued that the term implied that the empire was a fief of the church and thus was an insult to the Emperor. Bandinelli and the Pope maintained that it meant only "benefit," but they could hardly have been unaware of the ambiguity of the term. Most likely, they intended its use as a warning to Frederick Barbarossa.

The papal election of 1159, in which the majority of the cardinals chose Bandinelli as pope under the name Alexander III, witnessed a strong effort on the part of Frederick to secure the election of a candidate favourable to his policies. A minority of the cardinals chose Cardinal Octavian (who took the name Victor IV), thus beginning a line of antipopes. Alexander, faced by strong imperial opposition in Italy, fled to France in April 1162. This move prevented a total victory by the Emperor and enabled Alexander to build support in France and England, where he gained the recognition of kings Louis VII and Henry II. During this period Alexander also continued to hold the loyalty of most of the clergy in Italy, especially in the south, and many in Germany. He continued to press forward the program of church reform begun in the previous century under the leadership of Pope Gregory VII. He supported Thomas Becket, archbishop of Canterbury, in his dispute with King Henry II of England on the issue of the legal status of the clergy, despite the risk that he would lose much needed royal support. And he condemned certain propositions

of Henry's Constitutions of Clarendon. If Alexander's efforts on Becket's behalf were cautious, he did not compromise the principles on which the Archbishop's case was based. After the murder of Becket, Alexander found Henry easier to deal with and was able to reach some agreement.

Papal relations with the empire in the 12th century revolved around the problems, both theoretical and practical, created by two autonomous powers—one spiritual, the other temporal—vying for authority in the lives of men. The church claimed primary responsibility over moral decisions; secular authorities were attempting to carve out for themselves a sphere of competence over political matters. There was no clear-cut distinction between the two areas, though constant efforts were being made to define them. The important fact is that during the 11th and early 12th centuries medieval society had become increasingly a dualistic society, recognizing two sources of authority and attempting to reconcile them. Alexander found himself playing a large role in the political arena in defense of what he regarded as the legitimate authority of the church. The conflict with Frederick Barbarossa, which consumed most of his efforts in the 1160s and 1170s, was perceived by him as a defense of the papacy, on which the liberty of the church rested.

Following the return of Alexander III to Rome in 1165, which was the result of a more favourable political climate in Italy caused by the temporary absence of Frederick Barbarossa, the conflict entered its critical period. In 1166, Frederick returned to Italy and forced the Pope into exile once more. He entered Rome, where he received the imperial crown from his current antipope, Paschal III. Alexander now turned to the communes of northern Italy for support, finding in many of them a deep concern over the protection of their independence from the empire, a concern that united them with his cause. The result was the formation of the Lombard League, which provided the Pope with the support essential to carry on his conflict with Barbarossa.

Alexander was unwilling, however, to take extreme measures against the Emperor, whom he saw as the legitimate secular leader of Christendom. He rejected the notion proposed by the Byzantine emperor Manuel I Comnenus of a reunification of East and West under Byzantine rule and, instead, placed greater reliance on the Normans of southern Italy and the Lombard cities. It was this policy that was ultimately to prevail and to lay the foundation for the policies followed by the papal Curia in the 13th century. Frederick found himself increasingly isolated in Italy and at odds with powerful elements in Germany. His decisive defeat by the Lombards at Legnano (1176) paved the way for the Peace of Venice (1177), which closed this phase of the struggle.

Assessment. In his rule of the church, Alexander stood in the reform tradition and at the beginning of a line of lawyer-popes that would culminate in Innocent III. His concern for education was typical of his age, which witnessed the early development of the universities, in which he played a role both as teacher and later as pope (by ordering that the license to teach should be conferred on worthy candidates without charge). He presided over important synods at Beauvais (1160) and Tours (1163), as well as over the third Lateran Council (1179). He was among the first popes to express concern over the spread of the Catharist, or Albigensian, heresy in southern France.

With his death, in 1181, the church found itself in a more assured position than at his accession. His policies served as important signposts to his successors. Yet he had succeeded throughout his troubled reign in preserving the image of his moderation and in winning respect even from his enemies. He was not

merely one of the abler medieval popes but also one who won greater prestige for his office by his conduct. (J.M.Po.)

BIBLIOGRAPHY. A brief and useful account of the pontificate of Alexander III in English may be found in Marshall Baldwin, *Alexander III and the Twelfth Century* (1966). The standard biography is Marcel Pacaut, *Alexandre III* (1956), in French. Pacaut's views are also available in his study of *Frédéric Barberousse* (1967; Eng. trans. 1970). Of fundamental importance is A. Fliche and V. Martin, *Histoire de l'Église, depuis les origines jusqu'à nos jours*, vol. 9 (1953).

• **Alexander IV**, original name RINALDO DEI SEGNI (b. 1199, Anagni, near Rome—d. May 25, 1261, Viterbo, Papal States), pope from 1254 to 1261.

Alexander was appointed cardinal deacon (1227) and cardinal bishop of Ostia (1231) by his uncle Pope Gregory IX. After becoming pope, Alexander followed the policies of his predecessor Innocent IV: he continued war on Manfred, Emperor Frederick II's bastard son (who was crowned king of Sicily in 1258), by excommunicating him and investing Edmund, son of Henry III of England, with the papal fief of Sicily. He supported the friars at Paris against the secular professors, extended the Inquisition in France, worked for reunion between eastern Christians and Rome, and attempted in vain to organize a crusade against the Tatars.

• **Alexander (V)**, byname PETER OF CANDIA, Italian PIETRO DI CANDIA, original Greek name PETROS PHILARGOS (b. c. 1339, Candia, Crete—d. May 3, 1410, Bologna, Papal States), antipope from 1409 to 1410.

Alexander became a Franciscan theologian and then archbishop of Milan (1402). Pope Innocent VII appointed him cardinal (1405) and papal legate to Lombardy. Unanimously elected by the invalid Council of Pisa in 1409 when he was 70 years old, Alexander was pope for only 10 months. It was hoped that his election would swiftly terminate the Great Western Schism of 1378–1417, but the council did not persuade Pope Gregory XII and the antipope Benedict XIII to resign. A condominium of three popes resulted. In 1410 Alexander sent to Archbishop Zbynek of Prague a bull which ordered the burning of Wycliffe's heretical works. Alexander died mysteriously, some professing—though without proof—that he was poisoned by his successor, the antipope John XXIII.

• **Alexander VI**, original Spanish name in full RODRIGO DE BORJA Y DOMS, Italian RODRIGO BORGIA (b. 1431, Játiva, Aragon—d. Aug. 18, 1503, Rome), corrupt, worldly, and ambitious pope, whose neglect of the spiritual inheritance of the church contributed to the development of the Protestant Reformation.

Alexander VI, detail of a fresco by Pinturicchio, 1492–94; in the Vatican

Ainari—Art Resource/EB Inc

Rodrigo was born into the Spanish branch of the prominent and powerful Borgia family. His uncle Alonso de Borgia, bishop of Valencia (later cardinal), supervised his education and endowed him with ecclesiastical benefices while still in his teens. Rodrigo studied law at Bologna, and on Feb. 22, 1456, he was created a cardinal by his uncle, now Pope Calixtus III. As vice chancellor of the Roman Church, Rodrigo amassed enormous wealth and, despite a severe rebuke from Pope Pius II, lived as a Renaissance prince. He patronized the arts and fathered a number of children for whom he provided livings, mainly in Spain. Of a Roman noblewoman, Vanozza Catanei, he had four subsequently legitimized offspring—Juan, Cesare, Jofré, and Lucrezia—whose complicated careers troubled his pontificate.

Despite the shadow of simony that surrounded the disposal of his benefices among the papal electors, Rodrigo emerged from a tumultuous conclave on the night of Aug. 10–11, 1492, as Pope Alexander VI and received the acclaim of the Roman populace. He embarked upon a reform of papal finances and a vigorous pursuit of the war against the Ottoman Turks. His position was menaced by the French king Charles VIII, who invaded Italy in 1494 to vindicate his claim to the Kingdom of Naples. Charles, at the instigation of a rival cardinal of the influential della Rovere family, threatened the Pope with deposition and the convocation of a reform council. Politically isolated, Alexander sought assistance from the Turkish sovereign, Bayezid II. In the course of the Pope's meeting with King Charles in Rome in early 1495, however, he received the traditional obeisance from the French monarch. He still refused to support the King's claim to Naples and, by an alliance with Milan, Venice, and the Holy Roman emperor, eventually forced the French to withdraw from Italy.

In September 1493 Alexander created his teenaged son Cesare a cardinal, along with Alessandro Farnese (the brother of the papal favourite Giulia la Bella and the future pope Paul III). In the course of his pontificate Alexander appointed 47 cardinals to further his complicated dynastic, ecclesiastical, and political policies. His son Juan was made duke of Gandía (Spain) and was married to Maria Enriquez, the cousin of King Ferdinand IV of Castile; Jofré was married to Sancia, the granddaughter of the King of Naples; and Lucrezia was given first to Giovanni Sforza of Milan, and, when that marriage was annulled by papal decree on the grounds of impotence, she was married to Alfonso of Aragon. Upon his assassination Lucrezia received as a third husband Alfonso I d'Este, duke of Ferrara.

Tragedy struck the papal household on June 14, 1497, when Alexander's favourite son, Juan, was murdered. Gravely afflicted, Alexander announced a reform program and called for measures to restrain the luxury of the papal court, reorganize the Apostolic Chancery, and repress simony and concubinage. The Pontiff had shown great forbearance in dealing with the Dominican friar Girolamo Savonarola, who usurped political control in Florence in 1494, condemned the evils of the papal court, and called for the Pope's deposition, and, even before the friar's downfall in May 1498, theologians and men of affairs had expressed support for the papacy. Meanwhile, however, Alexander had returned to a policy of political intrigue.

Cesare resigned the cardinalate in 1498 and married Charlotte d'Albret in order to cement the Borgia alliance with the French king Louis XII, whose request for a marriage annulment was granted by the Pope. By a ruthless policy of siege and assassination, Cesare brought the north of Italy under his control; he con-

quered the duchies of Romagna, Umbria, and Emilia and earned the admiration of Niccolò Machiavelli, who used Cesare as the model for his classic on politics, *The Prince*. In Rome, Alexander destroyed the power of the Orsini and Colonna families and concluded an alliance with Spain, granting Isabella and Ferdinand the title of Catholic sovereigns. He negotiated the Treaty of Tordesillas (1494), which divided the New World into Portuguese and Spanish zones of exploration and which conferred on the monarchs the *patronato real*—royal control over the church in the mission lands they colonized.

As a patron of the arts, Alexander erected a centre for the University of Rome, restored the Castel Sant'Angelo, built the monumental mansion of the Apostolic Chancery, embellished the Vatican palaces, and persuaded Michelangelo to draw plans for the rebuilding of St. Peter's Basilica. He proclaimed the year 1500 a Holy Year of Jubilee and authorized its celebration with great pomp.

Recent attempts to whitewash Alexander's private conduct have proved abortive. While his religious convictions cannot be challenged, scandal accompanied his activities throughout his career. Even from a Renaissance viewpoint, his relentless pursuit of political goals and unremitting efforts to aggrandize his family were seen as excessive. Neither as corrupt as depicted by Machiavelli and by gossip nor as useful to the church's expansion as apologists would make him, Alexander VI holds a high place on the list of the so-called bad popes. (F.X.M.)

BIBLIOGRAPHY. Ludwig von Pastor, *Geschichte der Päpste seit dem Ausgang des Mittelalters* (*The History of the Popes, from the Close of the Middle Ages*, 2nd ed., vol. 5 and 6, ed. by F.I. Antrobus, 1901), an objective, documented biography based on Vatican sources; Michael de la Bedoyere, *The Meddlesome Friar and the Wayward Pope: The Story of the Conflict Between Savonarola and Alexander VI* (1958), a vigorous, popular account; G. Soranzo, *Il tempo di Alessandro VI papa e di Fra Girolamo Savonarola* (1960), a serious, critical study.

• **Alexander VII**, original name FABIO CHIGI (b. Feb. 13, 1599, Siena, Republic of Florence—d. May 22, 1667, Rome), pope from 1655 to 1667.

Grandnephew of Pope Paul V, Chigi served the church as vice legate at Ferrara and as nuncio at Cologne (1639–51). During the negotiations leading to the Peace of Westphalia (1648), he refused to deliberate with the Protestant heretics and urged the Catholic princes not to sacrifice the rights of the church. The princes, however, were tired of war and, despite his admonition, yielded to France and the Protestants. Secretary of state to Pope Innocent X in 1651 and made cardinal in 1652, Chigi was elected pope on April 7. His pontificate was marked by several disputes.

• **Alexander VIII**, original name PIETRO VITO OTTONONI (b. April 22, 1610, Venice—d. Feb. 1, 1691, Rome), pope from 1689 to 1691.

Made cardinal in 1652 and bishop of Brescia in 1654, he was elected pope on Oct. 6, 1689. He initiated measures that led eventually to a solution of the disputes between the papacy and Louis XIV of France. Alexander maintained the condemnation of the Gallican Articles of 1682, which restricted papal authority, and opposed Jansenism.

POLAND

• **Alexander**, Polish in full ALEKSANDER JAGIELLOŃCZYK (b. Aug. 5, 1461, Kraków, Pol.—d. Aug. 19, 1506, Vilnius, Lithuania), king of Poland (1501–06) of the Jagiellonian dynasty, successor to his brother John Albert.

Alexander carried on the hopeless struggle of the crown against the growing power of the Polish senate and nobles, who deprived him of financial control and curtailed his prerogative. For want of funds, Alexander was unable to assist the Grand Master of the Order of the Sword against Muscovite aggression, or prevent Tsar Ivan III from ravaging Lithuania with the Tatars. The utmost that the King could do was to garrison Smolensk and several other fortresses in his keep and to employ his wife, Helena, the Tsar's daughter, to mediate a truce between his father-in-law and himself. Only the death of Stephen, the great hospodar (ruler) of Moldavia, enabled Poland still to hold her own on the Danube. The liberality of Pope Julius II, who granted Alexander much-needed financial help, enabled the Polish king to restrain somewhat the arrogance of the Teutonic Knights in the Prussian provinces.

RUSSIA

• **Alexander I**, Russian in full ALEKSANDR PAVLOVICH (b. Dec. 23 [Dec. 12, old style], 1777, St. Petersburg, Russia—d. Dec. 1 [Nov. 19, O.S.], 1825, Taganrog), emperor of Russia (1801–25), who alternately fought and befriended Napoleon I during the Napoleonic Wars but who ultimately (1813–15) helped form the coalition that defeated the emperor of the French. He took part in the Congress of Vienna (1814–15), drove for the establish-

ment of the Holy Alliance (1815), and took part in the conferences that followed.

Early life. Aleksandr Pavlovich was the first child of Grand Duke Pavel Petrovich (later Paul I) and Grand Duchess Maria Fyodorovna, a princess of Württemberg-Montbéliard. His grandmother, the reigning empress Catherine II (the Great), took him from his parents and raised him herself to prepare him to succeed her. She was determined to disinherit her own son, Pavel, who repelled her by his instability.

A friend and disciple of the philosophers of the French Enlightenment, Catherine invited Denis Diderot, the encyclopaedist, to become Alexander's private tutor. When he declined, she chose Frédéric-César La Harpe, a Swiss citizen, a republican by conviction, and an excellent educator. He inspired deep affection in his pupil and permanently shaped his flexible and open mind.

As an adolescent, Alexander was allowed to visit his father at Gatchina, on the outskirts of St. Petersburg, away from the court. There, Pavel had created a ridiculous little kingdom where he devoted himself to military exercises and parades. Alexander received his military training there under the direction of a tough

and rigid officer, Aleksey Arakcheyev, who was faithfully attached to him and whom Alexander loved throughout his life.

Alexander's education was not continued after he was 16, when his grandmother married him to Princess Louise of Baden-Durlach, who was 14, in 1793. The precocious marriage had been arranged to guarantee descendants to the Romanov dynasty, and it was unhappy from the beginning. The sweet and charming girl who became Yelisaveta Alekseyevna was loved by everyone except her husband.

Catherine had already written the manifesto that deprived her son of his rights and designated her grandson as the heir to the throne, when she died suddenly on Nov. 17 (Nov. 6, O.S.), 1796. Alexander, who knew of it, did not dare to disclose the manifesto, and Pavel became emperor.

Ascent to the throne. Paul I's reign was a dark period for Russia. The monarch's tyrannical and bizarre behaviour led to a plot against him by certain nobles and military men, and he was assassinated during the night of March 23 (March 11, O.S.), 1801. Alexander became tsar the next day. The plotters had let him in on the secret, assuring him they would not kill his father but would only demand his abdication. Alexander believed them or, at least, wished to believe that all would go well.

After the darkness into which Paul had plunged Russia, Alexander appeared to his subjects as a radiant dawn. He was handsome, strong, pleasant, humane, and full of enthusiasm. He wanted his reign to be a happy one and dreamed of great and necessary reforms. With four friends, who were of noble families but motivated by liberal ideas—Prince Adam Czartoryski, Count Pavel Stroganov, Count Viktor Kochubey, and Nikolay Novosiltsev—he formed the Private Committee (Neglasny Komitet). Its avowed purpose was to frame "good laws, which are the source of the well-being of the Nation."

Alexander and his close advisers corrected many of the injustices of the preceding reign and made many administrative improvements. Their principal achievement was the initiation of a vast plan for public education, which involved the formation of many schools of different types, institutions for training teachers, and the founding of three new universities. Nevertheless, despite the humanitarian ideas inculcated in him by La Harpe and despite his own wish to make his people happy, Alexander lacked the energy necessary to carry out the most urgent reform, the abolition of serfdom. The institution of serfdom was, in the Tsar's own words, "a degradation" that kept Russia in a disastrously backward state. But to liberate the serfs, who composed three-quarters of the population, would arouse the hostility of their noble masters, who did not want to lose the slaves on whom their wealth and comfort depended. Serfdom was a continuing burden on the Russians. It prevented modernization of the country, which was at least a century behind the rest of Europe.

Out of a sincere desire to innovate, Alexander considered a constitution and "the limitation of the autocracy," but he recoiled before the danger of imposing sudden change on a nobility that rejected it. Moreover, he was a visionary who could not transform his dreams into reality. Because of his unstable personality, he would become intoxicated by the notion of grand projects, while balking at carrying them out. Finally, the "Western" theoretical education of Alexander and his young friends had not prepared them for gaining a clear vision of the realities of Russian life.

Early foreign policy. Displaying an astonishing inconstancy, Alexander abandoned his internal reforms to devote himself to foreign policy, to which he would commit the major portion of his reign. Sensitive to fluctuations in continental politics, he was a "European"

who hoped for peace and unity. He felt that he was called to be a mediator, like his grandmother, who had been called the "Arbiter of Europe."

As soon as he came to power, Alexander resealed an alliance with England that had been broken by Paul I. He nonetheless maintained good relations with France in the hope of "moderating" Bonaparte by restraining his spirit of conquest. A feeling of chivalry attached Alexander to the king of Prussia, Frederick William III, and to Queen Louisa, and a treaty of friendship was signed with Prussia. Later, he got on good terms with Austria. His idealism persuaded him that these alliances would lead to a European federation.

Napoleon had other ideas. His territorial encroachments, desire for world hegemony, and his coronation in 1804 as emperor forced Alexander to declare war against him. Assuming the role of commander in chief, he relied on the Austrian generals and scorned the counsel of the Russian general Prince Kutuzov, a shrewd strategist. The Russians and Austrians were defeated at Austerlitz, in Moravia, on Dec. 2, 1805, and the emperor Francis II was forced to sign the peace treaty, since his territory was occupied by the enemy. Russia remained intact behind its frontiers. Moreover, Napoleon wanted to spare the Tsar; he hoped to gain his friendship and to divide the world with him. Such a notion did not occur to Alexander, who wanted revenge.

In 1806 Napoleon defeated Prussia at Jena and Auerstädt. Despite the warnings of both his mother and his advisers, the Tsar rushed to the aid of his friend. The battles were fought in east Prussia. After a partial success at Eylau, the Russian Army, under General Bennigsen, was decimated at Friedland, on June 14, 1807. Then occurred the meeting (June 25) of the two emperors on a raft in the middle of the Niemen off Tilsit (now Sovetsk). The sequel of these events demonstrates that, in the course of the Tilsit interview, it was the Tsar of Russia who deceived the Emperor of the French. Seeking to gain time he used his charm to play the admiring friend. He accepted all the victor's conditions, promising to break with England, to adhere to the Continental System set up by Napoleon to isolate and weaken Great Britain, and to recognize the creation of the Grand Duchy of Warsaw, formed from the part of Poland given to Prussia during the Partition of 1795. In "recompense" Napoleon gave Alexander liberty to expand at the expense of Sweden and Turkey.

From Tilsit to the 1812 invasion. Most Russians were angered and humiliated by the Tilsit Alliance; they thought that breaking off trade with England would inevitably create a disastrous economic situation, but Alexander kept his plans secret and bided his time. He reorganized and strengthened his armies with the competent aid of Arakcheyev, the instructor from Gatchina who had become his indispensable colleague. Meanwhile, the monarch's popularity dropped; all levels of the population accused him of having uselessly sacrificed Russian blood and of ruining the country.

Alexander once again turned his attention to internal reforms. He placed responsibility for them on a remarkable legal writer, Mikhail Mikhaylovich Speransky. Of modest origins, Speransky's talent caused him to rise rapidly. He conceived a vast plan for total reorganization of Russian legal structures and authored a complete collection and a systematically coordinated digest of Russian laws. Only a very small part of his great plan was applied, for once again Alexander withdrew from any practical fulfillment, partly because foreign events distracted him from rebuilding his empire on new foundations.

Despite the strong Russian reaction against France, the Tsar again met Napoleon, at Erfurt in Saxony, in 1808, where he showed himself to have become distant from his Tilsit ally.

When a new war broke out between France and Austria in 1809, Alexander, despite his commitments, did not intervene in Napoleon's behalf, contenting himself with feigning a military advance. Napoleon reproached the Tsar for trading with England under cover of neutral vessels and for refusing him the hand of his sister, the grand duchess Anna Pavlovna. For his part Alexander tried in vain to obtain from Napoleon a commitment not to create an independent Kingdom of Poland. When Napoleon annexed the German territories on the Baltic, including the Grand Duchy of Oldenburg, a fief of the Tsar's brother-in-law, Alexander protested against what he considered a personal offense.

All of this was a pretext for military preparations on both sides. A violent shift of opinion against Napoleon appeared in Russia. The hostility toward France among the court compelled Alexander to exile his legal adviser, Speransky, an admirer of Napoleon and his Code. Changing his opinions yet again, the Tsar adopted the reactionary ideas of a patriotic group dominated by his favourite sister, the grand duchess Yekaterina Pavlovna. He judged that, under the conditions then prevailing, Russia had best keep its traditional institutions.

The defeat of Napoleon. Napoleon and his Grand Army of 600,000 men invaded Russia on June 24, 1812. The conflict that ensued was justly called the Patriotic War by the Russians; in it, the strong resistance and outstanding endurance of an entire people were displayed. The war transformed Alexander, suffusing him with energy and determination. The French advanced as rapidly as the Russians retreated, drawing them away from their bases. Napoleon thought that, once Moscow was taken, the Tsar would capitulate. But after the bloody Battle of Borodino, Napoleon entered a largely deserted Moscow, which was soon nearly destroyed by fire. The conqueror had to camp in a ruined city where he could not remain, and Alexander did not sue for peace. The Tsar, meanwhile, under pressure of public opinion, had named Kutuzov, whom he detested, supreme commander. The old warrior, through brilliant strategy and with the aid of heroic partisans, pursued the enemy and drove him from the country. The retreat from Russia, combined with Napoleon's reverses in Spain, precipitated his downfall.

Alexander had declared, "Napoleon or I: from now on we cannot reign together!" He said that the burning of Moscow had "illuminated his soul." He called Europe to arms, to rescue the people who had been enslaved by Napoleon's conquests. His enthusiasm, perseverance, and steadfast determination to triumph aroused the King of Prussia and the Emperor of Austria, and the enheartened allies were victorious at Leipzig in October 1813. This "Battle of Nations" could have been decisive, but Alexander wanted no peace until he reached Paris. He entered Paris triumphantly in March 1814. Napoleon abdicated, and the Tsar reluctantly accepted the restoration of the Bourbons, for whom he had little esteem, and imposed a constitutional charter on the new ruler, Louis XVIII. Alexander showed his generosity toward France, alleviating its condition as a defeated country and protesting that he had made war on Napoleon and not on the French people.

He had become the most powerful sovereign in Europe and the arbiter of its destinies, as he had wished. He inspired the convening of the greatest international congress in history in Vienna, in the autumn of 1814. It was a time of sumptuous feasts and also of diplomatic intrigues and bitter quarrels. The Tsar's allies, whom he had saved, now feared his power and opposed the annexation of Poland to Russia. It was his only claim in reward for what he had done, and he was determined to achieve it.

When Napoleon returned from his exile in Elba and regained the throne, the war resumed, ending with his final defeat by the allies at Waterloo on June 18, 1815. Again the victorious sovereigns met in Paris to frame a peace treaty, and once again Alexander intervened on behalf of France.

The final decade. This period marked a turning point for the Tsar. Since the invasion of his country, he had become religious; he read the Bible daily and prayed often. It was his frequent visits with the pietistic visionary Barbara Juliane Krüdenner in Paris that turned him into a mystic. She considered herself a prophetess sent to the Tsar by God, and, if her personal influence was of brief duration, Alexander nevertheless retained his newly found evangelical fervour and came to profess a nondogmatic "universal religion" strongly influenced by Quaker and Moravian beliefs.

Alexander obtained Poland, set it up as a kingdom with himself as king, and gave it a constitution, declaring his attachment to "free institutions" and his desire to "extend them throughout all the countries dependent on him." These words awakened great hopes in Russia, but, when the Tsar returned home after a long absence, he was no longer thinking of reform. He devoted his entire attention to the Russian Bible Society and to an unfortunate innovation, the military colonies, by which he attempted to settle soldiers and their families on the land so that they might enjoy more stable lives. These ill-conceived colonies brought great suffering to Russian soldiers and peasants alike.

After the Second Treaty of Paris, Alexander I, inspired by piety, formed the Holy Alliance, which was supposed to bring about a peace based on Christian love to the monarchs and peoples of Europe. It is possible to see in the alliance the beginnings of a European federation, but it would have been a federation with ecumenical, rather than political, foundations.

The idealistic Tsar's vision came to a sad end, for the alliance became a league of monarchs against their peoples. Its members—following up the congress with additional meetings at Aix-la-Chapelle, Troppau, Laibach (Ljubljana), and Verona—revealed themselves as the champions of despotism and the defenders of an order maintained by arms. When a series of uprisings against despotic regimes in Italy and Spain broke out, the "holy allies" responded with bloody repression. Alexander himself was badly shaken by the mutiny of his Semyonovsky regiment and thought he detected the presence of revolutionary radicalism.

This marked the end of his liberal dreams, for, from then on, all revolt appeared to him as a rebellion against God. He shocked Russia by refusing to support the Greeks, his coreligionists, when they rose against Turkish tyranny, maintaining they were rebels like any others. The Austrian chancellor, Prince Metternich, to whom the Tsar abandoned the conduct of European affairs, shamelessly exploited Alexander's state of mind.

After his return to Russia, he left everything in Arakcheyev's hands. For Alexander, it was a period of lassitude, discouragement, and dark thoughts. For Russia, it was a period of reaction, obscurantism, and struggle against real and imagined subversion. Alexander thought he saw "the reign of Satan" everywhere. In opposition, secret societies spread, composed of young men, mostly from the military, who sought to regenerate and liberalize the country. Plots were made. Alexander was warned of them, but he refused to act decisively. His crown weighed heavily on him, and he did not hide from his family and close friends his desire to abdicate.

The Empress was ill, and Alexander decided to take her to Taganrog, on the Azov Sea. This dismal, windy townlet was a strange watering place. The royal pair, however, who had been so long estranged, enjoyed a calm happiness there. Soon after, during a tour of inspection in the Crimea, Alexander contracted pneumonia or malaria and died on his return to Taganrog.

The Tsar's sudden death, his mysticism, and the bewilderment and the blunders of his entourage all went into the creation of the legend of his "departure" to a Siberian retreat. The refusal to open the Tsar's coffin after his death has only served to deepen the mystery.

• **Alexander II**, Russian in full ALEKSANDR NIKOLAYEVICH (b. April 29 [April 17, old style], 1818, Moscow—d. March 13 [March 1, O.S.], 1881, St. Petersburg, Russia), emperor of Russia (1855-81). His liberal education and distress at the outcome of the Crimean War, which had demonstrated Russia's backwardness, inspired him toward a great program of domestic reforms, the most important being the emancipation (1861) of the serfs. A period of repression after 1866 led to a resurgence of revolutionary terrorism and to Alexander's own assassination.

Alexander II, detail of a portrait by an unknown artist, 19th century; in the collection of Mrs. Merriweather Post, Hillwood, Washington, D.C.

Life. The future Alexander II was the eldest son of the grand duke Nikolay Pavlovich (who, in 1825, became the emperor Nicholas I) and his wife, Alexandra Fyodorovna (who, before her marriage to the Grand Duke and baptism into the Orthodox Church, had been the princess Charlotte of Prussia). Alexander's youth and early manhood were overshadowed by the overpowering personality of his dominating father, from whose authoritarian principles of government he was never to free himself. But at the same time, at the instigation of his mother, responsibility for the boy's moral and intellectual development was entrusted to the poet Vasily Zhukovsky, a humanitarian liberal and romantic. Alexander, a rather lazy boy of average intelligence, retained throughout his life traces of his old

tutor's romantic sensibility. The tensions created by the conflicting influences of Nicholas I and Zhukovsky left their mark on the future emperor's personality. Alexander II, like his uncle Alexander I before him (who was educated by a Swiss republican tutor, a follower of Rousseau), was to turn into a "liberalizing," or at any rate humanitarian, autocrat.

Alexander succeeded to the throne at the age of 36, following the death of his father in February 1855, at the height of the Crimean War. The war had revealed Russia's glaring backwardness in comparison with more advanced nations like England and France. Russian defeats, which had set the seal of final discredit on the oppressive regime of Nicholas I, had provoked among Russia's educated elite a general desire for drastic change. It was under the impact of this widespread urge that the Tsar embarked upon a series of reforms designed, through "modernization," to bring Russia into line with the more advanced Western countries.

Among the earliest concerns of the new emperor (once peace had been concluded in Paris in the spring of 1856 on terms considered harsh by the Russian public) was the improvement of communications. Russia at this time had only one railway line of significance, that linking the two capitals of St. Petersburg and Moscow. At Alexander's accession there were fewer than 600 miles (965 kilometres) of track; when he died in 1881, some 14,000 miles (22,525 kilometres) of railway were in operation. In Russia, as elsewhere, railway construction, in its turn, meant a general quickening of economic life in a hitherto predominantly feudal agricultural society. Joint-stock companies developed, as did banking and credit institutions. The movement of grain, Russia's major article of export, was facilitated.

The same effect was achieved by another measure of modernization, the abolition of serfdom. In the face of bitter opposition from landowning interests, Alexander II, overcoming his natural indolence, took an active personal part in the arduous legislative labours that on Feb. 19, 1861, culminated in the Emancipation Act. By a stroke of the autocrat's pen, tens of millions of human chattels were given their personal freedom. By means of a long-drawn-out redemption operation, moreover, they were also endowed with modest allotments of land. Although for a variety of reasons the reform failed in its ultimate object of creating an economically viable class of peasant proprietors, its psychological impact was immense. It has been described as "the greatest social movement since the French Revolution" and constituted a major step in the freeing of labour in Russia. Yet at the same time, it helped to undermine the already shaken economic foundations of Russia's landowning class.

The abolition of serfdom brought in its train a drastic overhaul of some of Russia's archaic administrative institutions. The most crying abuses of the old judicial system were remedied by the judicial statute of 1864. Russia, for the first time, was given a judicial system that in important respects could stand comparison with those of Western countries (in fact, in many particulars it followed that of France). Local government in its turn was remodelled by the statute of 1864, setting up elective local assemblies known as *zemstva*. Their gradual introduction extended the area of self-government, improved local welfare (education, hygiene, medical care, local crafts, agronomy), and brought the first rays of enlightenment to the benighted Russian villages. Before long *zemstvo* village schools powerfully supported the spread of rural literacy. Meanwhile, Dmitry Milyutin, an enlightened minister of war, was carrying out an extensive series of reforms affecting nearly every branch of the Russian military organization. The educative role of military service was underlined by a

marked improvement of military schools. The army statute of 1874 introduced conscription for the first time, making young men of all classes liable to military service.

The keynote of these reforms—and there were many lesser ones affecting various aspects of Russian life—was the modernization of Russia, its release from feudalism, and acceptance of Western culture and technology. Their aim and results were the reduction of class privilege, humanitarian progress, and economic development. Moreover, Alexander, from the moment of his accession, had instituted a political "thaw." Political prisoners had been released and Siberian exiles allowed to return. The personally tolerant emperor had removed or mitigated the heavy disabilities weighing on religious minorities, particularly Jews and sectarians. Restrictions on foreign travel had been lifted. Barbarous medieval punishments were abolished. The severity of Russian rule in Poland was relaxed. Yet, notwithstanding these measures, it would be wrong, as is sometimes done, to describe Alexander II as a liberal. He was in fact a firm upholder of autocratic principles, sincerely convinced both of his duty to maintain the God-given autocratic power he had inherited and of Russia's unreadiness for constitutional or representative government.

Practical experience only strengthened these convictions. Thus, the relaxation of Russian rule in Poland led to patriotic street demonstrations, attempted assassinations, and, finally, in 1863, to a national uprising that was only suppressed with some difficulty—and under threat of Western intervention on behalf of the Poles. Even more serious, from the Tsar's point of view, was the spread of nihilistic doctrines among Russian youth, producing radical leaflets, secret societies, and the beginnings of a revolutionary movement. The government, after 1862, had reacted increasingly with repressive police measures. A climax was reached in the spring of 1866, when Dmitry Karakozov, a young revolutionary, attempted to kill the Emperor. Alexander—who bore himself gallantly in the face of great danger—escaped almost by a miracle. The attempt, however, left its mark by completing his conversion to conservatism. For the next eight years, the Tsar's leading minister—maintaining his influence at least in part by frightening his master with real and imaginary dangers—was Pyotr Shuvalov, the head of the secret police.

The period of reaction following Karakozov's attempt coincided with a turning point in Alexander's personal life, the beginning of his liaison with Princess Yekaterina Dolgorukaya, a young girl to whom the aging emperor had become passionately attached. The affair, which it was impossible to conceal, absorbed the Tsar's energies while weakening his authority both in his own family circle (his wife, the former princess Marie of Hesse-Darmstadt, had borne him six sons and two daughters) and in St. Petersburg society. His sense of guilt, moreover, made him vulnerable to the pressures of the Pan-Slav nationalists, who used the ailing and bigoted empress as their advocate when in 1876 Serbia became involved in war with the Ottoman Empire. Although decidedly a man of peace, Alexander became the reluctant champion of the oppressed Slav peoples and in 1877 finally declared war on Turkey. Following initial setbacks, Russian arms eventually triumphed, and, early in 1878, the vanguard of the Russian armies stood encamped on the shores of the Sea of Marmara. The prime reward of Russian victory—seriously reduced by the European powers at the Congress of Berlin—was the independence of Bulgaria from Turkey. Appropriately, that country still honours Alexander II among its "founding fathers" with a statue in the heart of its capital, Sofia.

Comparative military failure in 1877, aggra-

vated by comparative diplomatic failure at the conference table, ushered in a major crisis in the Russian state. Beginning in 1879, there was a resurgence of revolutionary terrorism soon concentrated on the person of the Tsar himself. Following unsuccessful attempts to shoot him, to derail his train, and finally to blow up the Winter Palace in St. Petersburg itself, Alexander, who under personal attack had shown unflinching courage based on a fatalist philosophy, entrusted supreme power to a temporary dictator. The minister of the interior, Count Mikhail Loris-Melikov, was charged with exterminating the terrorist organization (calling itself People's Will) while at the same time conciliating moderate opinion, which had become alienated by the repressive policies pursued since 1866. At the same time, following the death of the Empress in 1880, the Tsar had privately married Yekaterina Dolgorukaya (who had borne him three children) and was planning to proclaim her his consort. To make this step palatable to the Russian public, he intended to couple the announcement with a modest concession to constitutionalist aspirations. There were to be two legislative commissions including indirectly elected representatives. This so-called Loris-Melikov Constitution, if implemented, might possibly have become the germ of constitutional development in Russia. But on the day when, after much hesitation, the Tsar finally signed the proclamation announcing his intentions (March 1, 1881), he was mortally wounded by bombs in a plot sponsored by People's Will.

It can be said that he was a great historical figure without being a great man, that what he did was more important than what he was. His Great Reforms indeed rank in importance with those of Peter the Great and Lenin, yet the impact of his personality was much inferior to theirs. The Tsar's place in history—a substantial one—is due almost entirely to his position as the absolute ruler of a vast empire at a critical stage in its development.

Assessment. The modernization of Russian institutions, though piecemeal, was extensive. In Alexander's reign, Russia built the base needed for emergence into capitalism and industrialization later in the century. At the same time, Russian expansion, especially in Asia, steadily gathered momentum. The sale of Alaska to the U.S. in 1867 was outweighed in importance by the acquisition of the Maritime Province from China (1858 and 1860) and the founding of Vladivostok as Russia's far eastern capital (1860), the definitive subjugation of the Caucasus (in the 1860s), and the conquest of central Asia (Khiva, Bokhara, Turkestan) in the 1870s. The contribution of the reign to the development of what was to be described as Russia's "cotton imperialism" was immense. Here also, the reign of Alexander paved the way for the later phases of Russian imperialism in Asia.

Alexander's importance lies chiefly in his efforts to assist Russia's emergence from the past. To some extent, he was, of course, the representative of forces—intellectual, economic, and political—that were stronger than himself or, indeed, any single individual. After the Crimean War, the modernization of Russia had indeed become imperative if Russia was to retain its position as a major European power. But even within the context of a wider movement, the role of Alexander II, through his position as autocratic ruler, was a highly important one. The Great Reforms, both in what they achieved and in what they failed to do, bear the imprint of his personality. Unfortunately, however, by placing great power in the hands of the influential reactionary minister K.P. Pobedonostsev—whom he appointed minister for church affairs (procurator of the Holy Synod) and entrusted with the education of his son and heir, the future Alexander III—Alexander II, perhaps unwittingly, did much

to frustrate his own reforming policies and to set Russia finally on the road to revolution.

of representative government, and supporter of Russian nationalism. He adopted programs, based on the concepts of Orthodoxy, autocracy, and *narodnost* (a belief in the Russian people), that included the Russification of national minorities in the Russian Empire as well as persecution of the non-Orthodox religious groups.

The future Alexander III was the second son of Alexander II and of Maria Aleksandrovna (Marie of Hesse-Darmstadt). In disposition he bore little resemblance to his softhearted, impressionable father and still less to his refined, chivalrous, yet complex granduncle, Alexander I. He gloried in the idea of being of the same rough texture as the great majority of his subjects. His straightforward manner savoured sometimes of gruffness, while his unadorned method of expressing himself harmonized well with his roughhewn, immobile features. During the first 20 years of his life, Alexander had no prospect of succeeding to the throne. He received only the perfunctory training given to grand dukes of that period, which did not go much beyond primary and secondary instruction, acquaintance with French, English, and German, and military drill. When he became heir apparent on the death of his elder brother Nikolay in 1865, he began to study the principles of law and administration under the jurist and political philosopher K.P. Pobedonostsev, who influenced the character of his reign by instilling into his mind hatred for representative government and the belief that zeal for Orthodoxy ought to be cultivated by every tsar.

The tsesarevich Nikolay, on his deathbed, had expressed a wish that his fiancée, Princess Dagmar of Denmark, thenceforward known as Maria Fyodorovna, should marry his successor. The marriage proved a most happy one. During his years as heir apparent—from

1865 to 1881—Alexander let it be known that certain of his ideas did not coincide with the principles of the existing government. He deprecated undue foreign influence in general and German influence in particular. His father, however, occasionally ridiculed the exaggerations of the Slavophiles and based his foreign policy on the Prussian alliance. The antagonism between father and son first appeared publicly during the Franco-German War, when the Tsar sympathized with Prussia and the tsarevich Alexander with the French. It reappeared in an intermittent fashion during the years 1875–79, when the disintegration of the Ottoman Empire posed serious problems for Europe. At first the Tsarevich was more Slavophile than the government, but he was disabused of his illusions during the Russo-Turkish War of 1877–78, when he commanded the left wing of the invading army. He was a conscientious commander, but he was mortified when most of what Russia had obtained by the Treaty of San Stefano was taken away at the Congress of Berlin under the chairmanship of the German chancellor Otto von Bismarck. To this disappointment, moreover, Bismarck shortly afterward added the German alliance with Austria for the express purpose of counteracting Russian designs in eastern Europe. Although the existence of the Austro-German alliance was not disclosed to the Russians until 1887, the Tsarevich reached the conclusion that for Russia the best thing to do was to prepare for future contingencies by a radical scheme of military and naval reorganization.

On March 13 (March 1, O.S.), 1881, Alexander II was assassinated, and the following day autocratic power passed to his son. In the last years of his reign, Alexander II had been much disturbed by the spread of nihilist conspiracies. On the very day of his death he signed an *ukaz* creating a number of consultative commissions that might have been transformed eventually into a representative assembly. Alexander III cancelled the *ukaz* before it was published and in the manifesto announcing his accession stated that he had no intention of limiting the autocratic power he had inherited. All the internal reforms that he initiated were intended to correct what he considered the too liberal tendencies of the previous reign. In his opinion, Russia was to be saved from anarchical disorders and revolutionary agitation not by the parliamentary institutions and so-called liberalism of western Europe but by the three principles of Orthodoxy, autocracy, and *narodnost*.

Alexander's political ideal was a nation containing only one nationality, one language, one religion, and one form of administration; and he did his utmost to prepare for the realization of this ideal by imposing the Russian language and Russian schools on his German, Polish, and Finnish subjects, by fostering Orthodoxy at the expense of other confessions, by persecuting the Jews, and by destroying the remnants of German, Polish, and Swedish institutions in the outlying provinces. In the other provinces he clipped the feeble wings of the *zemstvo* (an elective local administration resembling the county and parish councils in England) and placed the autonomous administration of the peasant communes under the supervision of landed proprietors appointed by the government. At the same time, he sought to strengthen and centralize the imperial administration and to bring it more under his personal control. In foreign affairs he was emphatically a man of peace but not a partisan of the doctrine of peace at any price. Though indignant at the conduct of Bismarck toward Russia, he avoided an open rupture with Germany and even revived for a time the Alliance of the Three Emperors between the

rulers of Germany, Russia, and Austria. It was only in the last years of his reign, especially after the accession of William II as German emperor in 1888, that Alexander adopted a more hostile attitude toward Germany. The termination of the Russo-German alliance in 1890 drove Alexander reluctantly into an alliance with France, a country that he strongly disliked as the breeding place of revolutions. In Central Asian affairs he followed the traditional policy of gradually extending Russian domination without provoking a conflict with Great Britain, and he never allowed bellicose partisans to get out of hand.

As a whole, Alexander's reign cannot be regarded as one of the eventful periods of Russian history; but it is arguable that under his hard, unsympathetic rule the country made some progress. (M.T.F.)

SCOTLAND

• **Alexander I** (b. c. 1080—d. April 1124, probably Stirling, Stirlingshire, Scot.), king of Scotland from 1107 to 1124.

The son of King Malcolm III Canmore (reigned 1058-93), Alexander succeeded to the throne upon the death of his brother King Edgar (ruled 1097-1107). In accordance with Edgar's instructions, Alexander allowed his younger brother and heir, David, to rule southern Scotland.

Alexander probably acknowledged King Henry I of England as his overlord. He married Henry's illegitimate daughter, Sibylla, and in 1114 he led a Scottish contingent in Henry's Welsh campaigns. Nevertheless, Alexander strove to preserve the independence of the Scottish Church from the English Church and to assert his will over the Scottish bishops. The outcome of these struggles was inconclusive at his death. He was succeeded by David (David I, 1124-53), who ruled over the whole of Scotland.

• **Alexander II** (b. Aug. 24, 1198, Haddington, East Lothian, Scot.—d. July 8, 1249, Kerrera Island, Argyll), king of Scotland from 1214 to 1249; he maintained peace with England and greatly strengthened the Scottish monarchy.

Alexander came to the throne on the death of his father, William I the Lion (reigned 1165-1214). When the English barons rebelled against King John (reigned 1199-1216) in 1215, Alexander sided with the insurgents in the hope of regaining territory he claimed in northern England. After the rebellion collapsed in 1217, he did homage to King Henry III (reigned 1216-72), and in 1221 he married Henry's sister, Joan (d. 1238). In 1237 Henry and Alexander concluded an agreement (Peace of York) by which the Scots king abandoned his claim to land in England but received in exchange several English estates. The boundary of Scotland was fixed approximately at its present location.

Meanwhile, Alexander was suppressing rebellious Scots lords and consolidating his rule over parts of Scotland that had hitherto only nominally acknowledged royal authority. In 1222 he subjugated Argyll. He died as he was preparing to conquer the Norwegian-held islands along Scotland's west coast.

• **Alexander III** (b. Sept. 4, 1241—d. March 18/19, 1286, near Kinghorn, Fife, Scot.), king of Scotland from 1249 to 1286, the last major ruler of the dynasty of kings descended from

Malcolm III Canmore (reigned 1058-93), who consolidated royal power in Scotland. Alexander left his kingdom independent, united, and prosperous, and his reign was viewed as a golden age by Scots caught up in the long, bloody conflict with England after his death.

The only son of King Alexander II (reigned 1214-49), Alexander III was seven years old when he came to the throne. In 1251 he was married to Margaret (d. 1275), the 11-year-old daughter of England's King Henry III. Henry immediately began plotting to obtain suzerainty over Scotland. In 1255 a pro-English party in Scotland seized Alexander, but two years later the anti-English party gained the upper hand and controlled the government until Alexander came of age the year 1262.

In 1263 Alexander repulsed an invasion by the Norwegian king Haakon IV, who ruled the islands along Scotland's west coast. Haakon's son, King Magnus V, in 1266 ceded to Alexander the Hebrides and the Isle of Man. Alexander was killed in 1286 when his horse fell over a cliff. Because his children were all dead, his infant grandchild Margaret "the Maid of Norway" (d. 1290) succeeded to the throne.

SELEUCID EMPIRE

• **Alexander BALAS**, also called **ALEXANDER EPIPHANES** (d. 145 BC), king of Syria and Pergamum (Greek Asia Minor) and ruler of the remains of the Seleucid Empire (150-145 BC).

The pretended son of Antiochus IV Epiphanes, he won the Seleucid throne with the help of mercenaries, challenging and slaying Demetrius I Soter, the direct Seleucid heir. With the support of the Roman Senate and the Egyptian Ptolemaic dynasty, he ruled the remains of the Seleucid Empire until he was killed in battle against Demetrius II Nicator, son of Demetrius I Soter.

During his reign, Alexander pacified Palestine by naming Jonathan Maccabeus as Jewish governor but alienated the population by his revelry while feigning interest in politics and Stoic philosophy.

SERBIA

• **Alexander**, Serbo-Croatian in full **ALEXANDAR KARAGEGEVIĆ** (b. Oct. 11 [Sept. 29, old style], 1806, Topola, Serbia—d. May 4 [April 22, O.S.], 1885, Temesvár, Binat, Austria-Hungary), prince of Serbia from 1842 to 1858.

The third son of Karageorge, who had led the movement to win Serb autonomy from the Ottoman Turks (1804-13), Alexander lived in exile until 1842, when the Skupština (Serb parliament) elected him prince of Serbia. Assuming the throne despite Russian challenges to his election and Turkish refusals to make his office hereditary, Alexander allowed his administration to be dominated by an oligarchy consisting of an elite group of senators. In an effort to modernize the Serb bureaucracy, it attempted to improve the principality's educational, legal, and judicial systems, as well as to foster the use of money and credit in Serbia's economy. Although Alexander and his senator-advisers were well intentioned, their innovations, which were quickly undermined by corruption and abuse, stimulated widespread discontent in Serbia's traditional peasant society. In addition, the new intelligentsia, created to provide trained personnel for the reformed bureaucracy, constituted another centre of opposition that encouraged emulation of western European parliamentary government, rather than the simple adoption of bureaucratic reforms.

Alexander responded to a revolt of the Serbs of south Hungary against the Hungarians in 1848 by refusing to support the revolutionary movement but allowing volunteers to cross

the border. He later succumbed to Austrian demands that Serbia refrain from aiding Russia and again maintain neutrality during the Crimean War (1853-56). Thus, he lost the support of the many Serbs who advocated pan-Slavism.

Although he overthrew some of the main oligarchs in 1857, the Skupština, which met the following year, insisted that he abdicate. Reluctantly agreeing, Alexander spent the remainder of his life in exile.

Consult the INDEX first

• **Alexander**, Serbo-Croatian in full **ALEXANDAR OBRENOVIĆ** (b. Aug. 14 [Aug. 2, old style], 1876, Belgrade—d. June 11 [May 29, O.S.], 1903, Belgrade), king of Serbia (1889-1903), whose unpopular authoritarian reign resulted not only in his assassination but also in the end of the Obrenović dynasty.

The only child of Prince (later King) Milan (reigned 1868-89) and his consort, Natalie, Alexander ascended the Serbian throne on March 6 (Feb. 22, O.S.), 1889, after his father had abdicated and named a regency council for the youthful Alexander. On April 13 (April 1, O.S.), 1893, Alexander dismissed the regency council and assumed active control of the government.

Initially well received, Alexander soon alienated a large segment of his supporters by excluding the popular pro-Russian Radical Party from his cabinets, abolishing (1894) the liberal constitution of 1889 in favour of the 1869 constitution (which limited the legislature's powers), frequently changing his Cabinet ministers, and bringing his pro-Austrian father (who had been living abroad since 1889) back to Serbia to become commander in chief of the armed forces (1897). When the press voiced its bitter opposition to Alexander's policies and authoritarian manner, the King, urged by his father, restricted the freedoms of the press and of association. An unsuccessful attempt on Milan's life (1899) brought more repressive measures, which particularly curtailed the activities of the Radicals.

Alexander's prestige reached a low point in 1900, when, despite the strong objections of his father and other political advisers, he declared his intention to marry his mistress, Draga Mašin, née Lunjevica, the widow of a Bohemian engineer, a former lady-in-waiting to Alexander's mother, and a woman 10 years his senior with a dubious reputation. Alexander's entire Cabinet resigned in protest.

The scandal forced Alexander to grant a more liberal constitution (1901) and to create a senate as the second house in the legislature. During his reign he also improved his state's economy, reformed the army, and tried to improve Serbia's international position by encouraging the revival of the Balkan alliances that were originally negotiated between 1865 and 1868 by King Michael (Mihailo Obrenović; reigned 1860-68).

But Alexander also made a mockery of constitutional government by suspending the constitution for a few hours when he wanted to make unconstitutional changes (1903). He also seemed on the verge of proclaiming Draga's brother as heir to the throne. Consequently, with opposition to Alexander mounting, the country generally welcomed the coup d'état by the military conspirators who invaded the royal palace and murdered Alexander, Draga, and some members of the court.

YUGOSLAVIA

• **Alexander I** (b. Dec. 16 [Dec. 4, old style], 1888, Cetinje, Montenegro—d. Oct. 9, 1934, Marseille), king of the Kingdom of Serbs, Croats, and Slovenes (1921-29) and of Yugoslavia (1929-34), who struggled to create a united state out of his politically and ethnically divided collection of nations.

The second son of Peter Karageorgević (king of Serbia 1903–18 and king of the Serbs, Croats, and Slovenes 1918–21) and Zorka of Montenegro, Alexander spent his early youth in Geneva with his father, then in exile from Serbia, and in 1899 went to St. Petersburg, where he entered the Russian imperial corps of pages (1904). In 1909, however, when his elder brother renounced his right of succession, Alexander, having become heir apparent, joined his family in Serbia.

A distinguished commander in the Balkan Wars of 1912–13, Alexander was appointed regent of Serbia by the ailing king Peter (June 24, 1914) and during World War I served as commander in chief of Serbia's armed forces, entering Belgrade in triumph on Oct. 31, 1918. As prince regent, he proclaimed the creation of the Kingdom of the Serbs, Croats, and Slovenes, on Dec. 1, 1918.

The instability of the new state was demonstrated by an attempted assassination on the day (June 28, 1921) that Alexander swore an oath to uphold the constitution. Nevertheless, on August 16 he succeeded his father as king and on June 8, 1922, he married Marie, a daughter of Ferdinand I of Romania. Later Alexander attempted to consolidate the rival nationality groups and political parties into a unified state.

During the 1920s mounting political tensions forced numerous changes in government ministers and culminated in the murder of several Croat deputies by a Montenegrin deputy during a Skupština (parliament) session (June 20, 1928). The Croat members then withdrew from the Skupština; and, because Alexander could neither negotiate a satisfactory compromise for restructuring the body nor form an effective government, he dissolved it, abolished the constitution of 1921, and established a royal dictatorship (Jan. 6, 1929).

Continuing his efforts to unify his subjects, he changed the name of the country to Yugoslavia (Oct. 3, 1929), outlawed all political parties based on ethnic, religious, or regional distinctions, reorganized the state administratively, and standardized legal systems, school curricula, and national holidays. He also tried to relieve the peasantry's financial difficulties, and he eased relations with Bulgaria (1933) and engaged Yugoslavia in the Little Entente (with Czechoslovakia and Romania) and the Balkan Entente, an alliance with Greece, Turkey, and Romania (1934).

In the process Alexander created a police state that required military support for survival. When a new constitution was promulgated (Sept. 3, 1931), the dictatorship was, in effect, given a legal foundation. Although Alexander's acts were at first well received, demands for a return to democratic forms intensified by 1932, when a major economic crisis resulting from the worldwide depression added to political dissatisfaction. As a result, Alexander seriously considered restoring a parliamentary form of government; but before he was able to do so, he was assassinated by an agent of Croatian separatists while making a state visit to France.

Alexander, SAINT: see Alexander 1 under Alexander (Papacy).

Alexander AETOLUS (fl. c. 280 BC), Greek poet of Pleuron, in Aetolia. He was appointed by Ptolemy II Philadelphus, Macedonian king of Egypt, to arrange and catalog the tragedies in the library at Alexandria. Nothing remains of his own tragic writing except the title of one play, *Astragalistae* ("The Dice Players"). A few fragments of his shorter writings are extant, including a brief appreciation of Euripides. The titles of Alexander's other works are known only because they were quoted by other writers.

Alexander BALAS: see Alexander Balas under Alexander (Seleucid Empire).

Alexander NEVSKY, SAINT, Russian ALEKSANDR NEVSKY, original name ALEKSANDR YAROSLAVICH (b. c. 1220, Vladimir, Grand Principality of Vladimir—d. Nov. 14, 1263, Gorodets; canonized in Russian Church 1547; feast days November 23, August 30), prince of Novgorod (1236–52) and of Kiev (1246–52) and grand prince of Vladimir (1252–63), who halted the eastward drive of the Germans and Swedes but collaborated with the Mongols in imposing their rule on Russia. By defeating a Swedish invasion force at the confluence of the Rivers Izhora and Neva (1240), he won the name Nevsky, "of the Neva."

Alexander was the son of Yaroslav II Vsevolodovich, grand prince of Vladimir, the foremost among the Russian rulers. In 1236 Alexander was elected prince—a figure who functioned as little more than military commander—of the city of Novgorod. In 1239 he married the daughter of the Prince of Polotsk.

When in 1240 the Swedes invaded Russia to punish the Novgorodians for encroaching on Finnish tribes and to bar Russia's access to the sea, Alexander defeated the Swedes at the confluence of the Rivers Izhora and Neva. His standing enhanced by his victory, he apparently began to intervene in the affairs of the city and was expelled a few months later.

When, urged by Pope Gregory IX to "Christianize" the Baltic region, the Teutonic Knights shortly thereafter invaded Russia, Novgorod invited Alexander to return. After a number of battles, Alexander decisively defeated the Germans in the famous "massacre on the ice" in April 1242 on a narrow channel between Lakes Chud (Peipus) and Pskov. Alexander, who continued to fight both the Swedes and Germans and eventually stopped their eastward expansion, also won many victories over the pagan Lithuanians and the Finnic peoples.

In the east, however, Mongol armies were conquering most of the politically fragmented Russian lands. Alexander's father, the grand prince Yaroslav, agreed to serve the new rulers of Russia but died in September 1246 of poisoning after his return from a visit to the Great Khan in Mongolia. When, in the ensuing struggle for the grand princely throne, Alexander and his younger brother Andrew appealed to Khan Batu of the Mongol Golden Horde, he sent them to the Great Khan. Violating Russian customs of seniority, the Great Khan appointed Andrew grand prince of Vladimir and Alexander prince of Kiev—probably because Alexander was Batu's favourite and Batu was in disfavour with the Great Khan. When Andrew began to conspire against the Mongol overlords with other Russian princes and western nations, Alexander went to Saray on the Volga and denounced his brother to Sartak, Batu's son, who sent an army to depose Andrew and installed Alexander as grand prince. Henceforth, for over a century, no northeastern Russian prince challenged the Mongol conquest. Alexander proceeded to restore Russia by building fortifications and churches and promulgating laws. As grand prince, he continued to rule Novgorod through his son Vasily, thus changing the constitutional basis of rule in Novgorod from personal sovereignty by invitation to institutional sovereignty by the principal Russian ruler. When, in 1255, Novgorod, tiring of grand princely rule, expelled Vasily and invited an opponent of Mongol hegemony, Alexander assembled an army and reinstalled his son.

In 1257 the Mongols, in order to levy taxes, took a census in most of Russia. It encountered little opposition, but when news of the impending enumeration reached Novgorod an uprising broke out. In 1258 Alexander, fearing that the Mongols would punish all of Russia for the Novgorodian revolt, helped force Novgorod to submit to the census and to Mongol taxation. This completed the process of imposing the Mongol yoke on northern Russia.

In 1262 uprisings broke out in many towns against the Muslim tax farmers of the Golden Horde, and Alexander made a fourth journey to Saray to avert reprisals. He succeeded in his mission, as well as in obtaining exemption for Russians from a draft of men for a planned invasion of Iran. Returning home, Alexander died on Nov. 14, 1263, in Gorodets on the Volga. After his death Russia once more disintegrated into many feuding principalities. His personal power, based upon support of the princes, boyars, and clergy, as well as the fear of Mongols, could not be transmitted to any other man, including his weak sons.

Whether Alexander was a quisling in his dealings with the Mongol conquerors is a question seldom posed by Russian historians, because some Russian princes had for centuries concluded alliances with Turkic steppe nomads in order to gain advantage in domestic rivalries. Because Alexander was a willing collaborator, he may have reduced the common people's suffering by interceding for them with the Khan. He was supported by the church, which thrived under Mongol protection and tax exemption and feared the anti-Mongol princes who negotiated with the papacy. For these reasons, Alexander by 1381 was elevated to the status of a local saint and was canonized by the Russian Orthodox Church in 1547. Alexander's son Daniel founded the house of Moscow, which subsequently reunited the northern Russian lands and ruled until 1598. Alexander was one of the great military commanders of his time, who protected Russia's western frontier against invasion by Swedes or Germans. This image of him was popular in northwestern Russia and has in succeeding centuries been adduced for propaganda purposes. Thus, after the conclusion of the war with Sweden, the Order of Alexander Nevsky was created in 1725, and during World War II (in July 1942), when Germany had deeply penetrated into the Soviet Union, Stalin pronounced Alexander Nevsky a national hero and established a military order in his name.

(R.He.)

BIBLIOGRAPHY. There is no book-length study of Nevsky in English. Information may be found in A.E. Presniakov, *The Formation of the Great Russian State: A Study of Russian History in the Thirteenth to Fifteenth Centuries* (1970; orig. pub. in Russian, 1918); and George Vernadsky, *A History of Russia*, vol. 3, *The Mongols and Russia* (1953).

Alexander OF APHRODISIAS (b. Aphrodisias, Caria, Anatolia; fl. c. 200), philosopher who is remembered for his commentaries on Aristotle's works and for his own studies on the soul and the mind.

Toward the end of the 2nd century, Alexander became head of the Lyceum at Athens, an academy then dominated by the syncretistic philosophy of Ammonius Saccas, who blended the doctrines of Plato and Aristotle. Alexander's commentaries were intended to reestablish Aristotle's views in their pure form. Among the extant commentaries are those on Aristotle's *Prior Analytics I*, the *Topics*, the *Meteorology*, the *De sensu*, and the *Metaphysics I–V*. Fragments of lost commentaries are found in later discussions by other writers. In antiquity Alexander's influence was due primarily to the commentaries, which earned him the title "the expositor," but in the Middle Ages he was better known for his original writings. The most important of these are *On Fate*, in which he defends free will against the Stoic doctrine of necessity, or predetermined human action; and *On the Soul*, in which he draws upon Aristotle's doctrine of the soul and the intellect. According to Alexander, the human thought process, which he calls the "mortal intellect," can function only with the

help of the "active intellect," which lies in every man and is yet identical with God. This doctrine was frequently and intensely debated in Europe after the beginning of the 13th century. In these disputes, which reflected disagreements over the proper interpretation of Aristotle's attitude toward personal immortality, the Alexandrists accepted Alexander's interpretation that man's intellect does not survive the death of the physical body.

Alexander OF HALES (b. c. 1170/85, Hales, Gloucestershire, Eng.—d. 1245, Paris), theologian and philosopher whose doctrines influenced the teachings of such thinkers as St. Bonaventure and John of La Rochelle. The *Summa theologica*, for centuries ascribed to him, is largely the work of followers.

Alexander studied and taught in Paris, receiving the degrees of master of arts (before 1210) and theology (1220). He was archdeacon of Coventry in 1235 and became a Franciscan (c. 1236). In Paris he founded the Schola Fratrum Minorum, where he was the first holder, possibly until his death, of the Franciscan chair.

Only the most general features of Alexander's theology and philosophy have been made clear: basically an Augustinian, he had to some extent taken into account the psychological, physical, and metaphysical doctrines of Aristotle, while discarding popular Avicennian tenets of emanations from a Godhead. The "Franciscan" theories of matter and form in spiritual creatures, of the multiplicity of forms, and of illumination combined with experience are probably Alexander's adaptations of similar theories of the Augustinian and other traditions. His original works, apart from sections of the *Summa* and of an *Expositio regulae* ("Exposition of the Rule"), include a commentary on the *Sentences* of Peter Lombard: *Quaestiones disputatae antequam esset frater* ("Questions Before Becoming a Brother . . ."); *Quodlibeta*; sermons; and a treatise on difficult words entitled *Exoticon*. Alexander was known to the Scholastics by the title Doctor Irrefragabilis (Impossible to Refute).

Alexander OF MACEDONIA: see Alexander III under Alexander (Macedonia).

Alexander OF PHERAE (d. 358 BC), despot of Pherae in Thessaly, Greece, from 369 to 358, whose tyranny caused the intervention of a number of city-states in Thessalian affairs. The other Thessalian cities, refusing to recognize Alexander as *tagos*, or head magistrate, appealed to the Thebans, who sent Pelopidas to their assistance. Alexander imprisoned Pelopidas, and the Thebans had to send a large army to procure his release. In 364 Pelopidas defeated Alexander at Cynoscephalae in Thessaly. Alexander was then compelled by Thebes to acknowledge the freedom of the Thessalian cities, to limit his rule to Pherae, and to join the Boeotian League. He was murdered at his wife's instigation.

Alexander OF TRALLES, Latin ALEXANDER TRALLIANUS (c. 525–c. 605), Byzantine physician who practiced and taught in Rome, best known for his treatise on pathology and therapy (in 12 books), which served as a basis for instruction long after his death. It was translated into Arabic and Latin (*Libri duodecim de re medica*) and was printed in Greek, Latin, and Greco-Latin editions throughout the 16th century.

Alexander PHILHELLENE: see Alexander I under Alexander (Macedonia).

Alexander POLYHISTOR, in full LUCIUS CORNELIUS ALEXANDER POLYHISTOR (b. Miletus, in Asia Minor—d. c. 35 BC, Laurentum, near Rome), philosopher, geographer, and historian whose fragmentary writings provide valuable

information on antiquarian and Jewish subjects.

Imprisoned by the Romans in the war of the Roman general Sulla against King Mithradates of Pontus, Alexander was sold as a slave to a patrician and taken to Rome to educate his master's children. After Alexander's release he continued to live in Italy as a Roman citizen.

Alexander's most important work, of which only fragments exist, consists of 42 books of historical and geographical accounts of nearly all the countries of the ancient world. His other notable treatise is about the Jews; it reproduces in paraphrase relevant excerpts from Jewish, Samaritan, and Gentile writers and is valuable for preserving the substance of Hellenistic Jewish authors of whom otherwise nothing would be known.

Alexander THE GREAT: see Alexander III under Alexander (Macedonia).

Alexander THE PAPHLAGONIAN (b. Abonouteichos, Paphlagonia; fl. 2nd century AD), celebrated impostor and worker of false oracles. The only account of his career occurs in an exposé by Lucian, whose investigations of Alexander's frauds led to a serious attempt on the writer's life.

Alexander established an oracle of Asclepius (the Greek god of healing) at his native town by staging a "rebirth" of the god in the form of a snake, which he called Glycon. He instituted mystical "rites" from which his particular enemies, the Christians and Epicureans, were excluded. He went so far as to celebrate a marriage between himself and the Moon. Through blackmail and other abuses he was able to amass a fortune.

Alexander THE WEALTHY: see Alexander I under Alexander (Macedonia).

Alexander, Franz (Gabriel) (b. Jan. 22, 1891, Budapest—d. March 8, 1964, Palm Springs, Calif., U.S.), physician and psychoanalyst sometimes referred to as the father of psychosomatic medicine because of his leading role in identifying emotional tension as a significant cause of physical illness.

Already a physician when he enrolled as the first student at the Berlin Psychoanalytic Institute (1919), Alexander became an assistant there and delivered a lecture series (1924–25) that grew into his first book, *Psychoanalyse der Gesamtpersönlichkeit* (1927; *The Psychoanalysis of the Total Personality*, 1930), a work developing the psychoanalytic theory of the superego and praised by Sigmund Freud. His success in applying psychoanalytic principles to the study and diagnosis of criminal personalities brought him an invitation to the United States (1930), where a professorship in psychoanalysis, the first post of its kind, was created for him at the University of Chicago. A year later, however, he went to Boston to collaborate with William Healy on a psychoanalytic study of delinquency, resulting in their book *Roots of Crime* (1935).

Alexander returned to Chicago in 1932 to establish the Chicago Institute for Psychoanalysis, which he directed until 1956. Under his leadership the institute attracted many analysts and students who conducted extensive research on emotional disturbance and psychosomatic disease, identifying various disorders with particular unconscious conflicts.

From 1938 to 1956 Alexander also served on the faculty of the department of psychiatry at the University of Illinois Medical School, Chicago. In 1956 he embarked on a new research program in psychotherapy and psychosomatic medicine at Mt. Sinai Hospital, Los Angeles. His work there, conducted in cooperation with the University of Southern California and the Southern California Psychoanalytic Institute, particularly explored the effect of the therapist's personality in the treatment process.

A notable authority on Freud, Alexander

considered it essential to elaborate Freud's views. Yet he retained a certain independence from Freud, viewing disturbed human relations, rather than disturbed sexuality, as the main cause of neurotic disorder. One of his important works on Freud is *Fundamentals of Psychoanalysis* (1948). His *Western Mind in Transition: An Eyewitness Story* (1960) is partly an autobiographical work, in combination with an analysis of modern civilization.

Alexander, Grover Cleveland (b. Feb. 26, 1887, Elba, Neb., U.S.—d. Nov. 4, 1950, St. Paul, Minn.), professional baseball player, one

Grover Cleveland Alexander, 1929
AP/Wide World Photos

of the finest right-handed pitchers in the history of the game, frequently considered the greatest master of control. From 1911 to 1930 he won 373 or 374 major league games (authorities differ) and lost 208. In his first season he won 28 games. For three consecutive years (1915–17) he won 30 or more games; in 1916, when he achieved 33 victories, 16 were shutouts, a major league record. His career total of 88 or 90 shutouts is second only to Walter Johnson's 110 or 113. Alexander's earned run average of 1.22 in 1915 is one of the lowest in baseball history.

Alexander pitched for three National League teams: the Philadelphia Phillies (1911–17, 1930), the Chicago Cubs (1918–26), and the St. Louis Cardinals (1926–29). His most dramatic performance came in the 1926 World Series when in the seventh and deciding game, he came in as a relief pitcher in the seventh inning with the Cardinals leading 3 to 2 and with the bases loaded. With two out, he struck out Tony Lazzeri. He then pitched scoreless eighth and ninth innings.

After service in World War I, he became an alcoholic and spent his last years in reduced circumstances. He was elected to the Baseball Hall of Fame in 1938.

Alexander (of Tunis), Harold (Rupert Leofric George) Alexander, 1st Earl, also called (1946–52) VISCOUNT ALEXANDER OF TUNIS, or (1942–46) SIR HAROLD ALEXANDER (b. Dec. 10, 1891, London—d. June 16, 1969, Slough, Buckinghamshire, Eng.), prominent

Lord Alexander of Tunis, oil on paper by John Gilroy, 1957; in the National Portrait Gallery, London

British field marshal in World War II noted for his North African campaigns against Field Marshal Erwin Rommel and for his later commands in Italy and western Europe.

The third son of the 4th Earl of Caledon, Alexander was educated at Harrow and the Royal Military College (Sandhurst) and was commissioned a second lieutenant in the Irish Guards in 1911. He fought with distinction in World War I and led a brigade on the North-West Frontier Province, India. In World War II Alexander commanded the British 1st Corps at Dunkirk, where he helped direct the evacuation of 300,000 troops; he was the last man to leave the beaches. In Burma (February 1942) he successfully extricated British and Indian troops before the advancing Japanese.

In the summer of 1942 Alexander was made British commander in chief in the Mediterranean theatre, where he formed a highly successful duo with his chief field commander, General Bernard Montgomery. Together they reorganized British forces and drove the Germans back from Egypt and across North Africa until the surrender of the Germans in Tunisia in May 1943. Alexander continued to drive the Germans from Sicily and southern Italy as commander of the Fifteenth Army Group (with Montgomery and the U.S. general George Patton as his field commanders), and in November 1944 he became commander in chief of all Allied forces in Italy. After the war he was named governor-general of Canada (1946–52); as a member of Winston Churchill's Conservative government, he served as minister of defense (1952–54) until his retirement. He was knighted in 1942 and made Viscount Alexander of Tunis in 1946 and an earl in 1952.

Alexander, James W., II, in full JAMES WADDELL ALEXANDER II (b. Sept. 19, 1888, Sea Bright, N.J., U.S.—d. Sept. 23, 1971, Princeton, N.J.), American mathematician and a founder of the branch of mathematics originally known as analysis situs, now called topology.

The son of John Alexander, the American painter who created murals for the Library of Congress, James studied mathematics and physics at Princeton University, obtaining a B.S. degree in 1910 and an M.S. degree the following year. In 1912 the mathematics department at Princeton invited him to join the faculty, a position he held until 1933 when he was asked to join the newly created Institute for Advanced Studies, also in Princeton, N.J. Alexander thus became one of the institute's initial members. He remained with the institute until his retirement in 1951.

Alexander's interest in the relationship of geometric figures that undergo transformation led to his developmental work in topology.

Alexander, Marcus Aurelius Severus: *see* Severus Alexander.

Alexander, Samuel (b. Jan. 6, 1859, Sydney, N.S.W. [Australia]—d. Sept. 13, 1938, Manchester, Eng.), philosopher who developed a metaphysics of emergent evolution involving time, space, matter, mind, and deity.

After studying in Melbourne, Alexander went to Balliol College, Oxford, in 1877 on a scholarship. In 1887 he received the Green Prize for "Moral Order and Progress" (1889), an essay on evolutionary ethics. Alexander's interest in evolution led him to relinquish a fellowship at Lincoln College, Oxford, in order to study (1890–91) experimental psychology under Hugo Münsterberg in Germany. In 1893 he became a professor at Owens College (later Victoria University of Manchester), where he remained until his retirement in 1924. He was awarded the Order of Merit in 1930.

As Gifford lecturer at Glasgow University, Alexander organized his philosophical thought into a comprehensive system published as *Space, Time and Deity* (1920), his only major

work. It explains the world as a single cosmic process with space-time as the basic cosmic matrix. "Emergents" (Gestalt-like properties) periodically arise as higher syntheses. Space-time thus produced matter, and matter in turn gave rise to mind (or "awareness") as a further, higher, qualitative synthesis.

Samuel Alexander, chalk drawing by Francis Dodd, 1932; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

"Deity" signifies the upper goal, the next higher level toward which the cosmic order spontaneously tends. In this hierarchy of change, the higher synthesis emerges from below but possesses genuinely new characteristics; hence in each instance the new synthesis is unpredictable. Alexander did not attempt to give an ultimate explanation for the world's existence; he tried merely to explain the world in terms of spontaneous creative tendencies.

Alexander, Sir William: *see* Stirling, William Alexander, 1st Earl of.

Alexander Archipelago, group of about 11,000 islands (actually the tops of submerged mountains) off the coast of southeastern Alaska, U.S. The islands are included within the Tongass National Forest and extend southward from Glacier Bay and Cross Sound to the Dixon Entrance. Among the largest islands (north-south) are Chichagof, Admiralty, Baranof, Kupreanof, Kuiu, Mitkof, Wrangell, Prince of Wales, and Revillagigedo. The chief cities are Sitka on Baranof and Ketchikan on Revillagigedo. Lumbering, fishing, fur collecting, and mining are the main economic activities of the area. The irregular shorelines of the islands are separated from the mainland by deep, narrow channels that form part of the Alaska Marine Highway system, or Inside Passage. The name was assigned by the U.S. Coast and Geodetic Survey in 1867 to honour Alexander II, tsar of Russia. Pop. (1991 est.) 38,800.

Alexander Epiphanes: *see* Alexander Balas under Alexander (Seleucid Empire).

Alexander Island, also called ALEXANDER LAND, large island in the Bellingshausen Sea, separated from the Antarctica mainland by the George VI Sound. An extremely rugged region with peaks up to 9,800 feet (2,987 m) above sea level, it is 270 miles (435 km) long and up to 125 miles (200 km) wide and has an area of about 16,700 square miles (43,250 square km). The Russian explorers Bellingshausen and Lazarev discovered the land in 1821 and named it after the Russian tsar. It was believed to be part of the mainland until 1940, when a U.S. expedition proved it to be an island, connected to the continent by a 20-mile-wide floating ice shelf. Alexander Island has been claimed by Britain (since 1908), by Chile (1940), and by Argentina (1942). It also has been the site of a British research station.

Alexander romance, any of a body of legends about the career of Alexander the Great, told and retold with varying emphasis and purpose by succeeding ages and civilizations.

The chief source of all Alexander romance literature was a folk epic written in Greek by a Hellenized Egyptian in Alexandria during

the 2nd century AD. Surviving translations and copies make its reconstruction possible. It portrayed Alexander as a national messianic hero, the natural son of an Egyptian wizard-king by the wife of Philip II of Macedonia. Magic and marvels played a subsidiary part in the epic—in the story of Alexander's birth, for example, and in his meeting with the Amazons in India. In later romances, however, marvels and exotic anecdotes predominated and gradually eclipsed the historical personality. Minor episodes in the original were filled out, often through "letters" supposedly written by or to Alexander, and an independent legend about his capture of the wild peoples of Gog and Magog was incorporated into several texts of many vernacular versions. An account of the Alexander legends was included in a 9th-century Old English translation of Orosius' history of the world. In the 11th century a Middle Irish Alexander romance appeared, and about 1100, the Middle High German *Annolied*. During the 12th century, Alexander appeared as a pattern of knightly chivalry in a succession of great poems, beginning with the *Roman d'Alexandre* by Albéric de Briançon. This work inspired the *Alexanderlied* by the German poet Lamprecht der Pfaffe. An Anglo-Norman poet, Thomas of Kent, wrote the *Roman de toute chevalerie* toward the end of the 12th century, and about 1275 this was remodeled to become the Middle English romance of *King Alisaunder*. Italian Alexander romances began to appear during the 14th century, closely followed by versions in Swedish, Danish, Scots, and (dating from a little earlier) in the Slavic languages.

Eastern accounts of Alexander's fabled career paid a good deal of attention to the Gog and Magog episode, a version of this story being included in the Qur'an. The Arabs, expanding Syrian versions of the legend, passed them on to the many peoples with whom they came in contact. Through them, the Persian poets, notably Nezami in the 12th century, gave the stories new form.

Alexander romance literature declined in the late 12th century, and, with the revival of classical scholarship during the Renaissance, historical accounts displaced the Alexander romances.

Alexander Severus (Roman emperor): *see* Severus Alexander.

Alexanderson, Ernst F.W., in full ERNST FREDERIK WERNER ALEXANDERSON (b. Jan. 25, 1878, Uppsala, Sweden—d. May, 1975, Schenectady, N.Y., U.S.), electrical engineer and television pioneer who developed a high-frequency alternator (a device that converts direct current into alternating current) capable of producing continuous radio waves and thereby revolutionized radio communication. In 1901 Alexanderson emigrated to the United States and the following year began working at the General Electric Company in Schenectady, N.Y., under Charles P. Steinmetz.

In 1906 Alexanderson completed his alternator, which in the ensuing years greatly improved transoceanic communication and firmly established the wireless as an important tool in shipping and warfare. He continued to improve the alternator and in addition made important improvements in radio antennas, electric railroads, ship propulsion, and electric motors. In 1916 he patented a selective-tuning device for radio receivers, which became an integral part of modern radio systems. He also developed the amplidyne, an extremely sophisticated automatic control system first used in factories to automate intricate manufacturing processes and used during World War II in conjunction with anti-aircraft guns.

Alexanderson demonstrated television in his

own home as early as 1927 and in 1930 gave the first public exhibition of television with a system that displayed the picture on a 7-foot (2-metre) screen. Alexanderson retired from his full-time position with General Electric in 1948 but continued to act as an engineering consultant. From 1952 he worked at Radio Corporation of America (RCA) as a consultant and was awarded his 321st patent in 1955 for the colour-television receiver that he developed for RCA.

Alexandra, in full ALEXANDRA CAROLINE MARY CHARLOTTE LOUISA JULIA, also called (1844–63) PRINCESS OF SCHLESWIG-HOLSTEIN-SONDERBURG-GLÜCKSBURG, or (1863–1901) PRINCESS OF WALES (b. Dec. 1, 1844, Copenhagen, Den.—d. Nov. 20, 1925, Sandringham, Norfolk, Eng.), queen consort of King Edward VII of Great Britain.

The eldest daughter of Christian IX of Denmark, Alexandra was married to Edward (then Albert Edward, prince of Wales) in St. George's Chapel, Windsor, on March 10, 1863. The exceptional beauty and graceful manner of the princess made her an immediate and lasting favourite with the British public. Of her six children, George, Duke of York, became King George V, and Maud became queen of Norway.

A serious illness in 1867 left Alexandra lame and accentuated a hereditary deafness. As queen she devoted much of her income and time to the poor and suffering; she founded the Imperial Military Nursing Service in 1902 and started Alexandra Rose Day to raise funds for British hospitals.

Alexandra, Russian in full ALEKSANDRA EYODOROVNA, original name ALIX, PRINCESS (prinzessin) VON HESSE-DARMSTADT (b. June 6, 1872, Darmstadt, Ger.—d. July 16/17, 1918, Yekaterinburg, Russia), consort of the Russian emperor Nicholas II. Her misrule while the emperor was commanding the Russian forces during World War I precipitated the collapse of the imperial government in March 1917.

Alexandra, empress of Russia, c. 1913

By courtesy of Hillwood, Washington, D.C.

A granddaughter of Queen Victoria and daughter of Louis IV, Grand Duke of Hesse-Darmstadt, Alexandra (German name Alix) married Nicholas in 1894 and came to dominate him. She proved to be unpopular at court and turned to mysticism for solace. Through her near-fanatical acceptance of Orthodoxy and her belief in autocratic rule, she felt it her sacred duty to help reassert Nicholas' absolute power, which had been limited by reforms in 1905. In 1904 the tsarevich Alexis was born; she had previously given birth to four daughters. The tsarevich suffered from hemophilia, and Alexandra's overwhelming concern for his life led her to seek the aid of a debauched "holy man" who possessed hypnotic powers, Grigory Yefimovich Rasputin (*q.v.*). She came to venerate Rasputin as a saint sent by God to

save the throne and as a voice of the common people, who, she believed, remained loyal to the emperor. Rasputin's influence was a public scandal, but Alexandra silenced all criticism. After Nicholas left for the front in August 1915, she arbitrarily dismissed capable ministers and replaced them with nonentities or dishonest careerists favoured by Rasputin. As a result, the administration became paralyzed and the regime discredited, and Alexandra came to be widely but erroneously believed to be a German agent. Yet she disregarded all warnings of coming changes, even the murder of Rasputin. After the October Revolution (1917), she, Nicholas, and their children were imprisoned by the Bolsheviks and were later shot to death.

Alexandra, town, Central Otago local government region, south-central South Island, New Zealand. It lies at the junction of the Clutha and Manuherikia rivers and is surrounded by three mountain ranges. Originally known as Lower Dunstan and Manuherikia, the settlement was named Alexandra South in 1863 to commemorate the marriage of the Danish princess Alexandra to Edward, prince of Wales, later King Edward VII. The name was subsequently shortened to Alexandra, and the town was constituted a borough in 1867.

Alluvial gold deposits in the Alexandra area, found in 1862, were mined until 1963. The surrounding countryside supports sheep pastures and fruit orchards; fruit packing is an important seasonal activity. Alexandra is also a holiday resort. Pop. (1996) 4,617.

Alexandretta (Turkey): *see* İskenderun.

Alexandria, Arabic AL-ISKANDARĪYAH, city and capital of al-Iskandarīyah *muhāfazah* (governorate), Lower Egypt. It is the country's chief seaport and the centre of a major industrial region. The city was the capital of Egypt after its founding by Alexander the Great in 332 BC and in antiquity was a centre of Hellenic scholarship and science.

A brief treatment of Alexandria follows. For full treatment (and a map), *see* MACROPAEDIA: Alexandria.

Alexandria lies along the Mediterranean Sea at the western edge of the Nile River delta, 114 miles (183 km) northwest of Cairo. It is built on a strip of land separating a low salt lake (Maryūt, or Marcotis) from the sea and on a T-shaped promontory extending into the Mediterranean. The stem of the T was originally a mole leading to the island of Pharos, but over time it was widened by silt to become an isthmus forming two harbours—the old harbour on the east and the modern harbour on the west. Alexandria has a Mediterranean climate with occasional heavy storms in the winter.

The inhabitants of Alexandria are mostly occupied in the trade of merchandise, harbour work, manufacturing, shipping, and fishing. The city's industries produce cotton textiles, paper, chocolate, processed foods, asphalt, and oil. Cotton is the most valuable export, followed by cereals and vegetables; imports include tea, coffee, timber, raw wool, and machinery.

At the heart of the city are the ancient quarters: Bruchium (Greek), Rakotis (Egyptian), Regio Judaeorum (Jewish), and Pharos. Midān at-Tahrīr (Liberation Square; formerly Muḥammad 'Alī Square) serves as the focal point of the modern city. Since the city engaged in massive demolition to make way for new construction projects in the 1990s, many archaeological sites from the ancient city have been uncovered, including the ruins of Pharos of Alexandria, the great lighthouse that is one of the Seven Wonders of the World. Pompey's Pillar and the Hadriatic catacombs of Kawm ash-Shuqāfah are two of the surviving structures. Although the famed Alexandrian libraries have long been destroyed, the Egyptian

government decided to build the extensive Bibliotheca Alexandrina (completed 2000), located near the site of the original structure, in its honour. Educational institutions include the University of Alexandria (1942) and the Mu'assah Hospital and College of Nursing. Other institutions in the city include the Library of the Greek Orthodox Patriarchate of Alexandria and the Greco-Roman Museum.

A beach-lined road, Al-Jaysh (Army) Street, runs for approximately 9 miles (14 km) along the coast. Alexandria is headquarters for the development of the Nile River delta and has extensive rail, road, and air service. The port is well developed, with vast networks of breakwaters, quays, and wharves. Area city and *muhāfazah*, 1,034 square miles (2,679 square km). Pop. (1996) city and *muhāfazah*, 3,328,196.

Alexandria, town, capital of Teleorman *județ* (county), southern Romania. It lies along the southward-flowing Vedea River in the Danube floodplain. Alexandria is a regional marketing centre for agricultural produce, mostly grain. The town also has flour mills and other food-processing plants. Manufactures include construction materials, chemicals, and rubber products. The town has a historical museum. Highways and railway connections extend throughout the county, from Alexandria to Roșiori de Vede, Videle, and Turnu Măgurele. Pop. (1997 est.) 59,007.

Alexandria, city, seat of Rapides parish, central Louisiana, U.S. The city lies along the Red River, opposite Pineville, about 100 miles (160 km) northwest of Baton Rouge. It was laid out (1805) at the rapids that then marked the head of river navigation and was named for the daughter of Alexander Fulton, on whose Spanish land grant the first settlement was made in the 1780s. Prior to the American Civil War, the community thrived on river commerce (cotton, sugarcane, and lumber). In May 1863 and again in March 1864 it was occupied by Union forces. When finally vacated (May 12–13, 1864), Alexandria was burned. Railroad expansion and exploitation of the dense pine and hardwood forests of the area helped in the town's restoration after the war.

Alexandria is a distribution centre for farm products, timber, and livestock. Light manufacturing (chemicals, soap, and fertilizers) is also important. Louisiana State University at Alexandria was opened in 1960; Louisiana College (1906) is in Pineville. Alexandria is the headquarters of Kisatchie National Forest. Inc. town, 1818; city, 1882. Pop. (2000) city, 46,342; Alexandria MSA, 126,337.

Alexandria, city, seat of Douglas county, west-central Minnesota, U.S., about 70 miles (115 km) northwest of St. Cloud, in a lake-resort region. Settled in 1858, it was organized as a township in 1866 and named for Alexander Kinkead, an early settler. The controversial Kensington Stone, with runic inscriptions describing a visit by Norsemen in 1362, is in the Runestone Museum. A 28-foot (9-metre) statue of a Viking and a gigantic reproduction of the stone promote the belief in early Norse exploration. Farming (oats, dairy products, soybeans, corn, livestock), manufacturing (packaging machinery, abrasives, metal products, plastics), and tourism are the city's economic mainstays. Inc. village, 1877; city, 1908. Pop. (2000) 8,820.

Alexandria, city, adjoining Arlington and Fairfax counties, northern Virginia, U.S., on the Potomac River (there bridged at the Maryland line), south of the District of Columbia. The site was settled in 1695, and a community known as Belhaven was founded in 1731. Organized in 1749, it was renamed for John Alexander, who had originally been granted the land, and was incorporated as a town in 1779. It has the unique distinction

Nineteenth-century town houses in Alexandria, Va.
Milt and Joan Mann from CameraMann

of being an independent city (without county affiliation), designated by an act of Congress (1852). George Washington helped to lay out its streets and drilled troops there during the French and Indian Wars.

From 1791 to 1847 Alexandria was part of the District of Columbia, after which it was ceded back to Virginia. Throughout the American Civil War (1861–65), Alexandria was occupied by Union troops. Its postwar development as a river port for shipping flour and tobacco was overshadowed by the growth of Baltimore. The city, although now mainly residential, has commercial and freight-rail operations and some manufactures (refrigerator cars, fertilizer, chemicals, lumber products).

Many colonial buildings survive, some of which are associated with Washington and with Henry ("Light-Horse Harry") Lee, father of Robert E. Lee. The Alexandria Academy was established in 1785. Washington, who maintained a house (now reconstructed) at Alexandria, served on the town council. His estate, Mount Vernon (9 miles [15 km] south), is a national historic landmark and contains his grave and that of his wife, Martha. Pop. (2000) 128,283.

Alexandria, Library of, the most famous library of classical antiquity. It formed part of the research institute at Alexandria in Egypt that is known as the Museum, or Alexandrian Museum.

The Alexandrian museum and library were founded and maintained by the long succession of the Ptolemies in Egypt from the beginning of the 3rd century BC. The library's initial organization was the work of Demetrius Phalereus, who was familiar with the achievements of the library at Athens. Both the museum and the library were organized in faculties, with a president-priest at the head and the salaries of the staff paid by the Egyptian king. A subsidiary "daughter library" was established about 235 BC by Ptolemy III in the Temple of Sarapis, the main museum and library being located in the palace precincts, in the district known as the Brucheium. It is not known how far the ideal of an international library—incorporating not only all Greek literature but also translations into Greek from the other languages of the Mediterranean, the Middle East, and India—was realized. It is certain that the library was in the main Greek; the only translation recorded was the Septuagint.

The library's editorial program included the establishment of the Alexandrian canon of Greek poets, the division of works into "books" as they are now known (probably to suit the standard length of rolls), and the gradual introduction of systems of punctuation and accentuation. The compilation of a national bibliography was entrusted to Callimachus. Though now lost, it survived into the Byzantine period as a standard reference work of Greek literature. The museum and library survived for many centuries but were destroyed in the civil war that occurred under the Roman emperor Aurelian in the late 3rd century AD; the "daughter library" was destroyed by Christians in AD 391. In 2002 the Egyptian government inaugurated a new library, the Bibliotheca Alexandrina, near the site of the ancient institution.

Alexandria, School of, the first Christian institution of higher learning, founded in the mid-2nd century AD in Alexandria, Egypt. Under its earliest known leaders (Pantaenus, Clement, and Origen), it became a leading centre of the allegorical method of biblical interpretation, espoused a rapprochement between Greek culture and Christian faith, and attempted to assert orthodox Christian teachings against heterodox views in an era of doctrinal flux. Opposing the School of Alexandria was the School of Antioch, which emphasized the literal interpretation of the Bible. *Compare* Antioch, School of.

Alexandria, Synod of (AD 362), a meeting of Christian bishops held in Alexandria, Egypt, summoned by the bishop of Alexandria, Athanasius. It allowed clergy that were readmitted to communion after making common cause with Arians to return to their former ecclesiastical status, provided they had not themselves subscribed to Arianism. The synod stated explicitly that the Holy Spirit, not a created being, is of the same substance as the Father and the Son, and it clearly defined the Christological terms "person" and "substance."

Alexandria Municipal Museum, Arabic MATHAF AL-BALADIYAH AL-ISKANDARI, also called GRECO-ROMAN MUSEUM, museum of Greek and Roman antiquities founded in 1892 and housed in Alexandria, Egypt, in a Greek Revival-style building opened in 1895.

The museum contains material found in Alexandria itself, as well as Ptolemaic and Roman objects from the Nile River delta, the Fayyūm of Upper Egypt, and Middle Egypt and antiquities from the Pharaonic period from the Alexandria area and the delta. Among the objects in the collection are a cast of the Rosetta Stone (the original was removed to the British Museum) and fine pieces of Hellenistic sculpture, including a large Attic funerary stela of the late 4th century BC. There is a colossal porphyry statue representing an emperor or Jesus Christ, found outside the At-tarin Mosque, Alexandria, and believed to be the largest example known in that material. Among the many other objects in the collection are terra-cottas, Tanagra figurines, capitals, pottery, silver objects, and coins.

Alexandrian Museum: *see* Museum.

Alexandrian rite, the system of liturgical practices and discipline found among Egyptians and Ethiopians of both the Eastern-rite Catholic and independent Christian churches.

The Alexandrian rite is historically associated with St. Mark the Evangelist, who traveled to Alexandria, the Greek-speaking capital of the diocese of Egypt and the cultural centre of the Eastern Roman Empire.

The liturgy of the modern Coptic Catholic church developed from the Byzantine liturgy attributed to St. John Chrysostom, as modified by Syrian and other influences. The service book is written in Coptic, with the Arabic

running in parallel columns, though readings from the Apostles and the Gospels are in Arabic.

The Ethiopian Orthodox liturgy (*see* Ethiopian Orthodox church) was derived from the Coptic and is in the classical Ethiopic Ge'ez language. The liturgy and Scriptures have been translated into Amharic, the dominant modern Ethiopic language.

Alexandrina, Lake, estuarine lagoon, southeastern South Australia, 45 miles (70 km) southeast of Adelaide. Together with contiguous Lake Albert and the long, narrow lagoon called The Coorong, it forms the mouth of the Murray River. About 23 miles (37 km) long and 13 miles (21 km) wide, the lake has a total surface area of 220 square miles (570 square km). The lake was visited by sealers in 1828 and crossed in 1830 by the explorer Charles Sturt, who named it after Princess Alexandrina (later Queen Victoria). Lake Alexandrina evoked early interest as a possible maritime outlet for the Murray River, but shallow depths (5 to 15 feet [1.5 to 4.5 m]) and a treacherous sandbar and islands at its seaward approach have precluded such development. Milang, a vegetable and dairy centre on the lake's western shore, did thrive as a river port until the completion of the railroad in 1884. Five barrages built across the lake's exits in 1940 prevent the intrusion of seawater upstream; and, as freshness has increased, irrigated agriculture has developed along the lake's shores.

alexandrine, verse form that is the leading measure in French poetry. It consists of a line of 12 syllables with major stresses on the 6th syllable (which precedes the medial caesura [pause]) and on the last syllable, and one secondary accent in each half line. Because six syllables is a normal breath group and the secondary stresses can be on any other syllables in the line, the alexandrine is a flexible form, adaptable to a wide range of subjects. Its structural metrical principle is stress according to sense; the form thus lends itself to the expression of simple or complex emotions, narrative description, or grandiose patriotic sentiment (it is known as the heroic line in French poetry).

The name alexandrine is probably derived from the early use of the verse in the French *Roman d'Alexandre*, a collection of romances that was compiled in the 12th century about the adventures of Alexander the Great. Revived in the 16th century by the poets of the Pléiade, especially Pierre de Ronsard, the alexandrine became, in the following century, the preeminent French verse form for dramatic and narrative poetry and reached its highest development in the classical tragedies of Pierre Corneille and Jean Racine. In the late 19th century, a loosening of structure occurred, notable in the work of Paul Verlaine; poets frequently wrote a modified alexandrine, a three-part line known as *vers romantique*, or *trimètre*.

In English versification, the alexandrine, also called iambic hexameter, contains six primary accents rather than the two major and two secondary accents of the French. Though it was introduced to England in the 16th century and was adapted to German and Dutch poetry in the 17th century, its success outside France has been limited.

Alexandrist, Italian ALESSANDRISTO, plural ALESSANDRISTI, any of the Italian philosophers of the Renaissance who, in the controversy about personal immortality, followed the explanation of Aristotle's *De anima* (*On the Soul*) given by Alexander of Aphrodisias, who held that it denied individual immortality.

Thomas Aquinas and his followers had main-

tained that Aristotle, who regarded reason as eternal, also regarded it as a faculty of the individual soul and so should be cited as believing that the individual soul is immortal. The Latin Averroists, on the other hand, had evolved a doctrine of universal (as opposed to individual) immortality, holding that the individual intellect is reabsorbed after death into the eternal intellect. The Alexandrists, however, led by Pietro Pomponazzi, denied that either the Thomist or the Averroist view could justly be attributed to Aristotle. Instead, they held that Aristotle considered the soul as a material and therefore a mortal entity, operating during life only under the authority of universal reason and organically connected with the body, on the dissolution of which it would become extinct.

Alexandropol (Armenia): see Gyumri.

Aléxandros (Greek personal name): see under Alexander.

Alexandroupolis, seaport, capital of the *nomós* (department) of Évros, western Thrace (Thráki), Greece. It is situated northwest of the Évros (Maritsa) River estuary on the Gulf of Ainos (Enez), an inlet of the Thracian Sea. Founded by the Turks as Dedeğaç in 1860, it began to grow with the marketing of its valonia oak after 1871 and further prospered with the arrival of the Istanbul-Thessaloniki railway in 1896. Long a bone of contention between Greece and Bulgaria, it was ceded to the latter in 1913, but the treaties of Neuilly (1919) and Sèvres (1920) granted it to Greece; and the Treaty of Lausanne (1923) confirmed this. In 1941 it was occupied by Bulgaria but was restored to Greece in 1944. It is the seat of a Greek Orthodox metropolitan bishop. Originally a fishing village, the city has become the centre of a developing agricultural hinterland raising grains (wheat and barley), tobacco, cattle, and silk. It has an airport. Pop. (1991 prelim.) 39,283.

Alexeïeff, Alexandre, original name (Russian) ALEKSANDR ALEKSANDROVICH ALEKSEYEV (b. Aug. 5, 1901, Kazan, Russia—d. Aug. 9, 1982, Paris, France), French motion-picture animator and an authority on the theory and technique of animation. He invented the pin-screen method of animation with his collaborator, later (1941) his wife, the animator Claire Parker.

Alexeïeff spent his childhood near Istanbul and studied at the school for naval cadets in St. Petersburg. After the Russian Revolution he studied painting in Paris and worked at the Chauve Souris Theatre there, where he designed sets and costumes for the Ballets Russes and Ballets Suedois. Alexeïeff's and Parker's first film using the pin screen was *Une Nuit sur le mont chauve* (1933; *Night on a Bare Mountain*). In pin-screen animation, a vertical metal surface is perforated by millions of holes into which headless pins are inserted; the pins are depressed to create shadows, and changes in the position of the pins are filmed frame by frame. *Le Nez* (1963; *The Nose*) and the titles to Orson Welles's *Le Procès* (1962; *The Trial*) were other Alexeïeff pin-screen productions.

Alexeïeff made greatly admired commercials by photographing swinging pendulums to which a light source was attached. He also made experimental and theatrical cartoons and illustrated books, using both wood engravings and still photographs of pin screens.

Alexis (b. c. 375, Thuri, Lucania [Italy]—d. c. 275 BC), one of the foremost writers of Middle and New Comedy at Athens, a low form of comedy that succeeded the Old Comedy of Aristophanes.

Alexis came from Thuri but apparently lived most of his long life in Athens; he was said

to have been Menander's uncle. According to Plutarch, he lived to the age of 106 and died on the stage while being crowned. Alexis is said to have written 245 plays, of which only 1,000 lines survive.

Alexis, Russian in full ALEKSEY MIKHAYLOVICH (b. March 9 [March 19, New Style], 1629, Moscow, Russia—d. Jan. 29 [Feb. 8], 1676, Moscow), tsar of Russia from 1645 to 1676.

The son of Michael, the first Romanov monarch of Russia (reigned 1613–45), Alexis received a superficial education from his tutor Boris Ivanovich Morozov before acceding to the throne at the age of 16. Morozov, who was also Alexis' brother-in-law, initially took charge of state affairs, but in 1648 a popular uprising in Moscow forced Alexis to exile Morozov.

Alexis bowed to the rebels' demands and convened a land assembly (*zemski sobor*), which in 1649 produced a new Russian code of laws (*Sobornoye Ulozheniye*), which legally defined serfdom. Morozov's place as the court favourite was taken first by Prince N.I. Odoyevsky and then by the patriarch Nikon. Russia accepted sovereignty over the Dnieper Cossacks in January 1654 and, in the following May, entered into a drawn-out war with Poland. This also involved a conflict with Sweden from 1656 to 1661. By the Treaty of Andrusovo (January 1667), which ended the Polish war, Russia won possession of Smolensk, Kiev, and the section of Ukraine lying east of the Dnieper River.

A notable event of Alexis' reign was the schism in the Russian Orthodox church. The tsar backed Nikon's efforts to revise Russian liturgical books and certain rituals that during the preceding century had departed from their Greek models. Although before long he became estranged from Nikon, whose violent temper and authoritarian inclinations had earned him many enemies, the revisions that Nikon initiated were retained, and the opponents of the reform were excommunicated. After the disgrace of Nikon, A.L. Ordyn-Nashchokin was the tsar's principal adviser until A.S. Matveyev took his place in 1671.

Tsar Alexis, detail of a portrait by an unknown artist, c. 1670; in the State Historical Museum, Moscow

During the reign of Alexis the peasants were tied to the land and to the landlord and were thus finally enserfed; the land assemblies were allowed to fall into gradual disuse; and the professional bureaucracy and regular army grew in importance. Because of Alexis' encouragement of trade with the West, foreign influences also began to crack the hitherto fairly solid wall separating Russia from its European neighbours. Dissatisfaction with his reign centred in the cities (which chafed under the economic competition of foreigners) and among the peasantry (which was deprived of the last vestiges of freedom). This social dissatisfaction expressed itself in frequent re-

bellions, the most savage of which was the peasant uprising on the eastern borderlands led by Stenka Razin from 1667 to 1671.

Virtually all the sources agree that Alexis was a gentle, warmhearted, and popular ruler. His main fault was weakness; throughout most of his reign, matters of state were handled by favourites, some of whom were incompetent or outright fools.

He was married twice, first to Mariya Ilinichna Miloslavskaya (with whom he had two sons, the future tsars Fyodor III and Ivan V, as well as several daughters), then to Natalya Kirillovna Naryshkina, whose son became Peter I the Great.

Alexis, Russian in full ALEKSEY PETROVICH (b. Feb. 18 [Feb. 28, New Style], 1690, Moscow, Russia—d. June 26 [July 7], 1718, St. Petersburg), heir to the throne of Russia, who was accused of trying to overthrow his father, Peter I the Great.

After his mother, Eudoxia, was forced to enter a convent (1698), Alexis was brought up by

Alexis, detail of an engraving by K. Vortman after a painting by J.P. Lüdden, 1729

Novosti Press Agency

his aunts and, after 1702, was educated by the tutor Baron Heinrich von Huysen. Although he dutifully obeyed his father—participating in the siege of Narva (1704) and directing the fortification of Moscow (1707) during the Great Northern War, studying at Dresden in Saxony (1709), and marrying Princess Sophia Charlotte of Brunswick-Wolfenbüttel (1711)—he never developed an enthusiasm for Peter's wars and reforms and became increasingly hostile toward his father. After Peter's second wife, Catherine, provided the tsar with another male heir in 1715, Alexis was offered the choice of either reforming his behaviour or renouncing his right of succession and becoming a monk.

When Peter later ordered Alexis to join him and the Russian army in Denmark (August 1716), Alexis fled to Vienna, where the Holy Roman emperor Charles VI gave him protection. Peter, fearing that his opponents might support Alexis as an alternative ruler, sent envoys to bring Alexis home. Promising him a full pardon, the envoys persuaded Alexis to return to Moscow (Jan. 31 [Feb. 11], 1718). He soon discovered, however, that his father's forgiveness was contingent upon renouncing his right to the throne and denouncing those who had helped him escape.

Although Alexis accepted these terms, Peter, using extraordinarily cruel methods, conducted an investigation of Alexis' supporters, discovered the existence of a potential movement of reaction for which Alexis might become a rallying point, and concluded that his son was involved in a treasonous conspiracy. Alexis was then forced to confess before the Senate, and a special court tried him and condemned him to death. Before his execution, however, he died in the Peter-Paul Fortress from shock and the effects of torture.

Alexis, Russian in full ALEKSEY, or ALEKSEI, NIKOLAYEVICH (b. Aug. 12 [Aug. 25, New Style], 1904, Peterhof, near St. Petersburg,

Russia—d. July 16/17, 1918, Yekaterinburg), only son of Nicholas II, the last tsar of Russia, and the tsarina Alexandra. He was the first male heir born to a reigning tsar since the 17th century.

Alexis was a hemophiliac, and at that time there was no medical treatment that could alleviate his condition or lessen his vulnerability to uncontrolled bleeding. The mystic healer Grigory Yefimovich Rasputin was summoned to the palace to help the little tsarevich during one of his bleeding episodes, and he achieved marked success in relieving Alexis' suffering. Whether through the hypnotic power of suggestion or the use of drugs or both, Rasputin proved indispensable in helping the boy survive several serious crises. Rasputin's subsequent acquisition of enormous influence at the imperial court was due primarily to the relief and gratitude of the royal couple.

In March 1917 the tsar received from the Duma a demand for his abdication. At first he favoured giving up the crown to Alexis, with his brother Grand Duke Michael as regent, but he changed his mind, feeling that the boy was too fragile. His abdication was made then in favour of the Grand Duke Michael, who, however, refused to accept the crown unless it were tendered to him by the will of the people. The last chance for a regime of constitutional monarchy was thus cut short.

Alexis was killed with the other members of his immediate family in a cellar where they had been confined by the Bolsheviks at Yekaterinburg.

Alexis I, Russian ALEKSEY, OF ALEKSEI, original name SERGEI VLADIMIROVICH SIMANSKY (b. Oct. 27 [Nov. 8, New Style], 1877, Moscow, Russia—d. April 17, 1970, Moscow), Russian Orthodox Patriarch of Moscow and All Russia (1945–70) whose allegiance to the Soviet government helped him strengthen the structure of the church within an officially atheistic country.

Born to an aristocratic family, Simansky received a law degree from the University of Moscow in 1899 before turning to religion. In 1902 he became a monk, receiving his doctoral degree in theology from the Moscow Theological Academy in 1904. By 1913 he had been consecrated bishop of Tivhkin and suffragan (subordinate bishop) of Novgorod, positions he was holding at the time of the Russian Revolution of 1917.

During the years 1918–41, while the new communist government operated under its antireligious policies, Alexis worked to stabilize church life, gaining renown within the church as bishop of Yamburg and suffragan of Petrograd (St. Petersburg) in 1921, metropolitan of Novgorod in 1932, and metropolitan of Leningrad in 1933. Joseph Stalin relaxed his opposition to the church in the face of Adolf Hitler's 1941 attack on the Soviet Union, and Alexis was notable for remaining in Leningrad (St. Petersburg) to organize the church's support of the Red Army.

When the church was officially reestablished in Russia in 1943, Alexis was elected a permanent member of the Holy Synod, and in 1945 he succeeded Patriarch Sergius as patriarch of Moscow, leader of the Russian Orthodox church. He actively supported Soviet political policies and attempted to unite Eastern Orthodoxy in the Western Hemisphere. One of his last acts was to establish an Independent Orthodox church in the United States.

Alexis II, Russian ALEKSEY, OF ALEKSEI, original name ALEKSEY MIKHAILOVICH RIDIGER, Ridiger also spelled RÜDIGER (b. Feb. 23, 1929, Tallinn, Estonia), Russian Orthodox Patriarch of Moscow and All Russia from 1990.

Ridiger graduated from the Leningrad Theological Academy in 1953 and was consecrated an archbishop in 1964. From 1968 to 1986 he was metropolitan of Tallinn and Esto-

nia; in July 1986 he became metropolitan of Leningrad (St. Petersburg) and Novgorod. He was a permanent member of the Holy Synod and administrator of affairs for the Moscow patriarchate before succeeding Patriarch Pimen on June 7, 1990. Alexis II was the first patriarch in Soviet history to be chosen without government pressure; candidates were nominated from the floor, and the election was conducted by secret ballot.

He quickly became an outspoken advocate of the rights of the church, asking the Soviet government to allow the option of religious education in the state schools and urging it to pass a "freedom of conscience" law legalizing religious worship. He was among the dignitaries present for the investiture of Boris Yeltsin as president of the Russian republic in July 1991, and during the abortive coup in August 1991, at Yeltsin's request, he denounced the detention of Soviet president Mikhail Gorbachev and anathematized all those involved. Alexis issued statements condemning anti-Semitism and refusing to identify the church with Russian nationalism.

Alexis, SAINT, Russian ALEKSEY, OF ALEKSEI (b. c. 1295, Moscow, Russia—d. 1378, Moscow; canonized 1448; feast day Oct. 5), metropolitan of Moscow from 1354 to 1378 and the first representative of the Russian Orthodox church to take a truly active role in governing Russia.

Alexis became regent during the short reign of Ivan the Fair (1353–59), great-great-grandson of Prince Alexander Nevsky, the greatest leader of medieval Russia. Alexis followed the two political principles of Nevsky: first, to defer to the powerful Tatars (a branch of the Mongols) who had conquered Russia in the 13th century and who were to dominate Russian affairs for nearly 200 years; and second, to resist the encroachments, military and political, of the Western powers, particularly the Lithuanians, who sought to subjugate Russia.

Alexis wielded the power of his office with cunning political precision. He carried the favour of the Tatars by curing the sick wife of the khan. He excommunicated the princes of Tver and Smolensk because they were conspiring with the Lithuanians. Above all, Alexis strove for political consolidation of the fragmented Russian provincial outposts, and he succeeded. A mere three years after his death, the united Russian Army defeated the Mongols at the Battle of Kulikovo Pole (Sept. 8, 1380) signaling the end of Tatar domination.

Alexis, Willibald, pseudonym of GEORG WILHELM HEINRICH HÄRING (b. June 29, 1798, Breslau, Silesia, Prussia [now Wrocław, Pol.]—d. Dec. 16, 1871, Arnstadt, Ger.), German writer and critic best known for his historical novels about Brandenburg and Prussia.

Alexis grew up in Berlin. After service as a volunteer in the campaign of 1815, he studied law at Berlin and Breslau but abandoned his legal career for writing after the success of his literary hoax *Walladmor* (1824), a parody of Scott published as "freely translated from the

English of Walter Scott." The joke, detrimental to Alexis' literary reputation, was repeated in the more ambitious and original novel *Schloss Avalon* (1827). Although his home was in Berlin, where he edited the *Berliner Konversationsblatt* (1827–35) and contributed essays and reviews to literary journals, he traveled widely in Europe and recounted his experiences in travel books, among them *Herbstreise durch Skandinavien* (1828; "Autumn Journey Through Scandinavia").

With *Cabanis* (1832), a story of the age of Frederick the Great, Alexis embarked on a cycle of novels intended to bring to light forgotten but significant periods of Prussian history. He continually experimented with methods of presentation. *Der Roland von Berlin* (1840) portrays the struggle for power in the 15th century between the municipal authorities of Berlin-Kölln and the ruler of Brandenburg; *Der falsche Woldemar* (1842; "The False Woldemar") recounts the rise and fall of a 14th-century pretender. In the first part of *Die Hosen des Herrn von Bredow* (1846–48; "The Trousers of the Lord of Bredow"), Alexis reveals qualities as a humorist, though the concluding section, describing the elector Joachim's ineffectual opposition to Luther's teaching, strikes a more serious note. In *Ruhe ist die erste Bürgerpflicht* (1852; "Rest Is the First Civic Duty"), the activities of criminals are presented as symptomatic of Prussian degeneracy in 1806. The sequel, *Isegrimm* (1854), foreshadows a rebirth of patriotism.

Alexis was the first writer to reveal the poetic aspects of the Brandenburg landscape. His writing is uneven; effective realistic description alternates with a romantic mysticism. From 1842 until 1860 he edited, almost singlehandedly, a remarkable collection of famous lawsuits, *Der neue Pitaval* ("The New Pitaval"). He suffered a stroke in 1856 and later retired permanently to Arnstadt.

Alexius, name of Byzantine emperors, grouped below chronologically and indicated by the symbol ●.

● **Alexius I COMNENUS** (b. 1048, Constantinople [now Istanbul, Tur.]—d. Aug. 15, 1118), Byzantine emperor (1081–1118) at the time of the First Crusade, who founded the Comnenian dynasty and partially restored the strength of the empire after its defeats by the Normans and Turks in the 11th century.

The third son of John Comnenus and a nephew of Isaac I (emperor 1057–59), Alexius came of a distinguished Byzantine landed family and was one of the military magnates who had long urged more effective defense measures, particularly against the Turks' encroaching on Byzantine provinces in eastern and central Anatolia. From 1068 to 1081 he gave able military service during the short reigns of Romanus IV, Michael VII, and Nicephorus III. Then, with the support of his brother Isaac and his mother, the formidable Anna Dalassena, and with that of the powerful Ducas family, to which his wife, Irene, belonged, he seized the Byzantine throne from Nicephorus III.

Alexius was crowned on April 4, 1081. After more than 50 years of ineffective or short-lived rulers, Alexius, in the words of Anna Comnena, his daughter and biographer, found the empire "at its last gasp," but his military ability and diplomatic gifts enabled him to retrieve the situation. He drove back the south Italian Normans, headed by Robert Guiscard, who were invading western Greece (1081–82). This victory was achieved with Venetian naval help, bought at the cost of granting Venice extensive trading privileges in the Byzantine Empire. In 1091 he defeated the Pechenegs, Turkic nomads who had been continually surging over the Danube River

Willibald Alexis, engraving by an unknown artist
Bavaria Verlag

into the Balkans. Alexius halted the further encroachment of the Seljuq Turks, who had already established the Sultanate of Rûm (or Konya) in central Anatolia. He made agreements with Sulaymân ibn Qutalmîsh of Konya (1081) and subsequently with his son Qilîch Arslan (1093), as well as with other Muslim rulers on Byzantium's eastern border.

Alexius I Comnenus, detail of an illumination from a Greek manuscript; in the Vatican Library (Cod. Vat. Gr. 666)

Biblioteca Apostolica Vaticana

At home, Alexius' policy of strengthening the central authority and building up professional military and naval forces resulted in increased Byzantine strength in western and southern Anatolia and eastern Mediterranean waters. But he was unable or unwilling to limit the considerable powers of the landed magnates who had threatened the unity of the empire in the past. Indeed, he strengthened their position by further concessions, and he had to reward services, military and otherwise, by granting fiscal rights over specified areas. This method, which was to be increasingly employed by his successors, inevitably weakened central revenues and imperial authority. He repressed heresy and maintained the traditional imperial role of protecting the Eastern Orthodox church, but he did not hesitate to seize ecclesiastical treasure when in financial need. He was subsequently called to account for this by the church.

To later generations Alexius appeared as the ruler who pulled the empire together at a crucial time, thus enabling it to survive until 1204, and in part until 1453, but modern scholars tend to regard him, together with his successors John II (reigned 1118–43) and Manuel I (reigned 1143–80), as effecting only stopgap measures. But judgments of Alexius must be tempered by allowing for the extent to which he was handicapped by the inherited internal weaknesses of the Byzantine state and, even more, by the series of crises precipitated by the western European crusaders from 1097 onward. The crusading movement, motivated partly by a desire to recapture the holy city of Jerusalem, partly by the hope of acquiring new territory, increasingly encroached on Byzantine preserves and frustrated Alexius' foreign policy, which was primarily directed toward the reestablishment of imperial authority in Anatolia. His relations with Muslim powers were disrupted on occasion and former valued Byzantine possessions, such as Antioch, passed into the hands of arrogant Western princelings, who even introduced Latin Christianity in place of Greek. Thus, it was during Alexius' reign that the last phase of the clash between the Latin West and the Greek East was inaugurated. He did regain some control

over western Anatolia; he also advanced into the southeast Taurus region, securing much of the fertile coastal plain around Adana and Tarsus, as well as penetrating farther south along the Syrian coast. But neither Alexius nor succeeding Comnenian emperors were able to establish permanent control over the Latin crusader principalities. Nor was the Byzantine Empire immune from further Norman attacks on its western islands and provinces—as in 1107–08, when Alexius successfully repulsed Bohemond I of Antioch's assault on Avlona in western Greece. Continual Latin (particularly Norman) attacks, constant thrusts from Muslim principalities, the rising power of Hungary and the Balkan principalities—all conspired to surround Byzantium with potentially hostile forces. Even Alexius' diplomacy, whatever its apparent success, could not avert the continual erosion that ultimately led to the Ottoman conquest. (J.M.H.)

BIBLIOGRAPHY. Information on Alexius' life and rule may be found in George Ostrogorsky, *History of the Byzantine State*, rev. ed. (1969, reissued 1980), a useful brief account with bibliography; J.M. Hussey (ed.), *The Cambridge Medieval History*, new ed., vol. 4, pt. 1 (1966), with full bibliography; J.M. Hussey, *Church & Learning in the Byzantine Empire, 867–1185* (1937, reissued 1963); Steven Runciman, *A History of the Crusades*, vol. 1 (1951, reissued 1975), a vivid presentation, particularly of the Byzantine point of view; and Michael Angold, *The Byzantine Empire, 1025–1204: A Political History* (1984).

• **Alexius II COMNENUS** (b. 1169—d. November 1183, Constantinople [now Istanbul, Tur.]), Byzantine emperor from 1180 to 1183.

Alexius was the son of Manuel I Comnenus and Mary, daughter of Raymond, prince of Antioch. When his father died on Sept. 24, 1180, Alexius became emperor at the age of 11, with his mother as regent. She, in turn, entrusted the government to her favourite, the unpopular and incapable Alexius (Manuel's nephew). Because Mary was a Latin she was widely opposed, but plotters, who included Alexius II's sister Mary and her husband, Renier of Montferrat, failed to overthrow the regency. Andronicus I Comnenus, Manuel's cousin, eventually succeeded in deposing the regency; he advanced through Asia Minor and was waiting at Chalcedon when anti-Latin riots broke out in the capital (May 1182). The regent Alexius was captured and blinded, and Andronicus entered the capital as the protector of Alexius II. He promptly had his opponents executed, including the dowager empress Mary, whose death warrant her son Alexius had to sign. Crowned coemperor in September 1183, Andronicus subsequently had Alexius strangled.

• **Alexius III ANGELUS** (d. 1211, Nicaea, Nicaean Empire [now Iznik, Tur.]), Byzantine emperor from 1195 to 1203. He was the second son of Andronicus Angelus, grandson of Alexius I. In 1195 he was proclaimed emperor by the troops; he captured his brother, the emperor Isaac II, at Stagira in Macedonia and had him blinded and imprisoned. Crowned in April 1195, Alexius III was a weak and greedy emperor, and his coup d'état had disastrous results. Byzantine prestige declined in the Balkans, where his failure to aid his son-in-law Stephen Prvovenčani (Stephen the First-Crowned) caused the latter to turn to the Bulgars for help. Campaigns against the Bulgars ended in defeat (1195 and 1196), and intrigues and diplomacy were equally unsuccessful because the new Bulgarian ruler, Kalojan, acknowledged the pope's supremacy instead of that of Constantinople.

In 1203 the crusaders restored Isaac II and his son (crowned Alexius IV). Alexius III fled the capital with what treasure he could collect and escaped to Thrace. After an unsuccessful attempt to recover the throne, he wandered

about Greece and surrendered to Boniface of Montferrat, then master of a great part of the Balkan Peninsula, but left his protection and sought shelter with Michael I, despot of Epirus. Finally, he went to Asia Minor, where his son-in-law Theodore Lascaris was holding his own against the Latins. Alexius, joined by the Sultan of Iconium (modern Konya, Tur.), demanded Theodore's crown and, when it was refused, marched against him. Taken prisoner by Theodore in 1211, Alexius was sent to a monastery at Nicaea, where he died.

• **Alexius IV ANGELUS** (d. Feb. 8, 1204, Constantinople [now Istanbul, Tur.]), Byzantine emperor from 1203 to 1204.

Alexius was the son of Emperor Isaac II. He regained control of his rights to the Byzantine throne with the help of the Fourth Crusade but was deposed soon after by a national revolt. Imprisoned in 1195 with his father, who had also been blinded, by Alexius III, he escaped in 1201 and joined his sister and her husband, Philip of Swabia, in Germany. Promising funds, supplies, and troops to conquer Egypt, the maintenance of 500 Western knights in the Holy Land, and submission of the Byzantine church to Rome, Alexius convinced Philip of Swabia, Crusade leader Boniface of Montferrat, and their Venetian allies to divert the Fourth Crusade to Constantinople in order to reinstate Alexius and his father as coemperors; this plan was accomplished in 1203. The new emperors, however, were unable to pay their debts to the West or to unite the two churches. Heavy taxation, as well as wanton behaviour on the part of the crusaders in Constantinople, caused a national revolt led by Alexius Ducas Murtzuphlus, the son-in-law of Alexius III. Alexius Ducas, who was proclaimed emperor in January 1204, as Alexius V, had Alexius IV strangled. Isaac died in prison a few days later.

• **Alexius V DUCAS MURTZUPHLUS** (d. 1204, Constantinople [now Istanbul, Tur.]), Byzantine emperor in 1204, son-in-law of Alexius III Angelus. He led a Greek revolt against the coemperors Isaac II and Alexius IV, who had been reinstated by the Latin crusaders, and became the last Greek emperor of a united Byzantium before its overthrow and partition by the crusaders. In January 1204 Alexius began his four-month reign by imprisoning the deposed Alexius IV, whom he later had strangled. The leader of the anti-Latin party in Constantinople, he disavowed Alexius IV's debt to the crusaders and demanded their withdrawal from Constantinople. They instead besieged the city, and three days later (April 12, 1204) Alexius fled to join the fugitive Alexius III. Alexius III, however, blinded him. He was then captured by the crusaders, who put him to death as the murderer of Alexius IV by casting him from the top of a column in Constantinople.

Alfa Romeo SpA, Italian manufacturer of high-priced sports cars and other vehicles. The company was operated by the Italian government through its state holding company, IRI (Istituto per la Ricostruzione Industriale), until 1986, when it was sold to Fiat SpA. Headquarters are in Milan.

The company was formed in 1910 as Anonima Lombarda Fabbrica Automobili (ALFA) when a group of Italian businessmen bought a failing French-owned auto plant located near Milan, hired noted auto designer Giuseppe Merosi, and began making racing and sports cars. In 1915 the company was taken over by industrialist Nicola Romeo and became a limited partnership, which during World War I produced mainly industrial and military vehicles and engines.

After the war, Romeo renamed the company Alfa Romeo and began producing prizewinning race cars again. The company held onto its preeminent position in the racing world

until 1933, when it was nationalized by the Italian government, which did not provide the financial support necessary to continue the production of quality cars. After World War II, Alfa Romeo shifted its emphasis from custom car production to broader automobile production, though it continued to produce higher-priced sports cars. It became involved in joint ventures with other companies for the manufacture of engines and engine parts and industrial vehicles.

alfalfa, also called LUCERNE, or PURPLE MEDIC (*Medicago sativa*), perennial, clover-like, leguminous plant of the pea family (Fabaceae), known for its tolerance of drought, heat, and cold; for the remarkable productivity and the quality of its herbage; and for its value in soil improvement. It is widely grown primarily for hay, pasturage, and silage. The plant, which grows 30–90 cm (1–3 feet) tall, arises from a much-branched crown that is partially embedded in the surface layer of soil. As the plant develops, numerous stems bearing many trifoliate leaves arise from the crown buds. Racemes of small flowers arise from the upper axillary buds of the stems. With approaching maturity, corkscrew coiled pods containing from two to eight or more seeds develop abundantly in regions with much sunshine, moderate heat, dry weather, and pollinating insects.

The primary root of alfalfa attains great depths. When 20 or more years of age, this taproot may descend as much as 15 m (50 feet) or more where the subsoil is porous. This accounts for the unusual ability of the plant to tolerate drought. The roots of seedling plants

Alfalfa (*Medicago sativa*)

Isaac Geib from Grant Heilman

are known to penetrate the soil for 90 cm (3 feet) at two months and for 180 cm (6 feet) with plants five months of age. Not infrequently, newly established fields of alfalfa survive severe summer drought and heat when other leguminous plants with shallower and more branching roots succumb.

Alfalfa has a remarkable capacity for rapid and abundant regeneration of dense growths of new stems and leaves following cutting. This makes possible from 1 to as many as 13 crops of hay in one growing season. The frequency of harvest and the total seasonal yields are dependent largely on the length of the growing season, the adaptability of the soil, the abundance of sunshine, and especially the amount and distribution of rainfall or irrigation during the growing season. Green leafy alfalfa hay is very nutritious and palatable, containing about 16 percent proteins and 8 percent mineral constituents. In addition it is rich in vitamins A, E, D, and K.

Like all crops, alfalfa is beset with hazards of

climate, diseases, and insects. Among the more serious of these are winterkill, bacterial wilt disease, alfalfa weevil, lugus bugs, grasshoppers, spotted aphid, and leafhoppers. In humid areas and in irrigated areas, alfalfa stands of three or more years of age have often become badly thinned by infestations of the soil-borne bacterial wilt organism *Phytophthora infestans*.

Alfasi, Isaac ben Jacob, Alfasi also spelled AL-PHASI, also called RABBI ISAAC FASI, or (by acronym) RIF (b. 1013, near Fès, Morocco—d. 1103, Lucena, Spain), Talmudic scholar who wrote a codification of the Talmud known as *Sefer Ha-Halakhot* ("Book of Laws"), which ranks with the great codes of Maimonides and Karo.

Alfasi lived most of his life in Fès and there wrote his digest of the Talmud, the rabbinical compendium of law, lore, and commentary. In 1088 two of his enemies denounced him to the government on an unknown charge. He fled to Spain, where, in Lucena, he became head of the Jewish community and established a noted Talmudic academy. Alfasi provoked a rebirth of Talmudic study in Spain, and his influence was instrumental in changing the centre of such studies from the Eastern to the Western world.

His codification deals with the Talmud's legal aspects, or Halakha (Hebrew Law), including civil, criminal, and religious law. It omits all homiletical passages as well as portions relating to religious duties practicable only in Palestine. He concentrated on the actual text, which had been neglected. His commentaries summarize the thought of the geonim who presided over the two great Jewish academies in Babylonia between the middle of the 7th and the end of the 13th century. In addition, his work played a major role in establishing the primacy of the Babylonian Talmud, as edited and revised by three generations of ancient sages, over the Palestinian Talmud, the final compilation of which had been interrupted by external pressures. Alfasi's *Sefer Ha-Halakhot* is still important in yeshiva studies.

Alferov, Zhores, in full ZHORES IVANOVICH ALFEROV (b. March 15, 1930, Vitebsk, Belorussia, U.S.S.R. [now in Belarus]), Soviet physicist who, with Herbert Kroemer and Jack S. Kilby, was awarded the Nobel Prize for Physics in 2000 for their work that laid the foundations for the modern era of computers and information technology.

Alferov received a doctorate in physics and mathematics from the A.F. Ioffe Physico-Technical Institute in Leningrad (now St. Petersburg) in 1970; he became director of the institute in 1987. In the 1950s he began work to develop fast optoelectronic and microelectronic components made from semiconductor heterostructures. (While most computer chips and other semiconductor components were made from one kind of material, such as silicon, heterostructure semiconductors were made from layers of different materials.) Using Kroemer's theory, which suggested that a heterostructure transistor was superior to a conventional transistor, Alferov and his research team developed the first practical heterostructure electronic device in 1966. They then pioneered electronic components made from heterostructures, including the first heterostructure laser, which both Alferov and Kroemer had proposed independently in 1963. Heterostructure solid-state lasers made possible fibre-optic communications, and heterostructure devices were later used in communications satellites, bar-code readers, cellular telephone communications, and other products.

Alfieri, Vittorio, Conte (Count) (b. Jan. 16, 1749, Asti, Piedmont—d. Oct. 8, 1803, Florence), Italian tragic poet whose predominant theme was the overthrow of tyranny. Through his lyrics and dramas he helped to revive the

national spirit of Italy and so earned the title of precursor of the Risorgimento.

Educated at the Military Academy of Turin, Alfieri became an ensign. A distaste for mili-

Alfieri, detail of an oil painting by François-Xavier Fabre; in the Museo Civico, Turin, Italy

By courtesy of the Museo Civico, Turin, Italy

tary life led him to obtain leave to travel through most of Europe. In England he found the political liberty that became his ideal, and in France the literature that influenced him most profoundly. He studied Voltaire, J.-J. Rousseau, and, above all, Montesquieu.

Alfieri settled in Turin in 1772 and resigned his commission the following year. To divert himself, he wrote *Cleopatra*, a tragedy performed with great success in 1775. Thereupon Alfieri decided to devote himself to literature. He began a methodical study of the classics and of the Italian poets, and since he expressed himself mainly in French, the language of the ruling classes in Turin, he went to Tuscany to familiarize himself with pure Italian.

By 1782 he had written 14 tragedies as well as many poems (including four odes in the series *L'America libera*, on American independence, to which a fifth ode was added in 1783) and a political treatise on tyranny, in prose, *Della tirannide* (1777). He also hailed the fall of the Bastille with an ode, "Parigi sbastigliata" (1789). Ten of the tragedies were printed at Siena in 1783.

Alfieri's genius was essentially dramatic. His rough, forthright, and concise style was chosen deliberately, so that he could persuade the oppressed and the resigned to accept his political ideas and inspire them to heroic deeds. Nearly always, Alfieri's tragedies present the struggle between a champion of liberty and a tyrant. Of the 19 tragedies that he approved for publication in the Paris edition of 1787–89, the best are *Filippo*, *Antigone*, *Oreste*, and, above all, *Mirra* and *Saul*. *Saul*, his masterpiece, is often considered the most powerful drama in the Italian theatre. Alfieri's autobiography, published posthumously as *Vita di Vittorio Alfieri scritta da esso* (1804; *The Life of Vittorio Alfieri Written by Himself*), is his chief work in prose. He also wrote sonnets, comedies, satires, and epigrams.

alfisol, soil type of humid, wooded regions, characterized by a well-developed clay (argillic) horizon. Second in abundance among the 10 orders of soil taxonomy, alfisols occupy between 10 and 15 percent of the world's land surface and occur on all the continents, but especially where broadleaf forests are established. Good fertility and physical properties, combined with occurrence in areas climatically favourable for agriculture, make these soils among the world's most productive. Wheat and corn (maize) are major crops in the three largest areas of alfisols—parts of Canada, the United States, and northern Europe. High moisture content, which distinguishes these soils from the drier mollisols, is responsible for mobilizing clay minerals and ensuring that

the chemical bases of calcium, magnesium, and potassium, which are prerequisites for soil fertility, are released by weathering about as rapidly as they are leached out.

Alföld (Hungary): see Great Alföld.

Alfonsine Tables, also spelled ALPHONSINE TABLES, set of astronomical tables prepared in Toledo, Spain, for King Alfonso X of León and Castile under the direction of Jehuda ben Moses Cohen and Isaac ben Sid. Completed in 1252, these tables were based on the Ptolemaic theory, which assumed that the Earth was at the centre of the solar system. They enabled astronomers to calculate eclipses and the positions of the planets for any given moment. The original form of the tables was cast into a handier arrangement in Paris around 1320, and manuscript copies of this version rapidly propagated throughout Europe. For more than two centuries they were considered the best astronomical tables available. They were first printed in 1483. The tables were an important source of information for the young Copernicus, but his own work superseded them in the 1550s.

alfonsino, any of the 10 species of exclusively marine fishes constituting the family Berycidae (order Beryciformes). The family contains two genera, *Beryx* and *Centroberyx*. Representatives occur in deep-sea habitats of the Atlantic, Pacific, and Indian oceans.

B. splendens of the African coast is an edible, deepwater species that reaches a length of 60 centimetres (2 feet). It is spectacularly coloured, the lower half being silvery and the upper portions and fins bright scarlet.

Alfonso, name of rulers grouped below by country and indicated by the symbol ●.

Foreign-language equivalents:

- French Alphonse
- Italian Alfonso
- Portuguese Afonso
- Spanish Alfonso

FERRARA

● **Alfonso I** (b. July 21, 1476, Ferrara, Duchy of Ferrara—d. Oct. 31, 1534, Ferrara), duke of Ferrara from 1505, a noted Renaissance prince of the House of Este, an engineer and patron of the arts.

Alfonso succeeded to the duchy at the death of his father, Ercole I. He employed the poet Ludovico Ariosto and the painters Titian and Giovanni Bellini, and made Ferrara's artillery the best in Italy. In the political sphere, Alfonso maintained Ferrara against the expanding power of the papacy by allying himself with France. Lucrezia Borgia, whom he married in 1501, bore him seven children.

KONGO

● **Alfonso I**: see Afonso I under Afonso (Kongo).

NAPLES

● **Alfonso I**: see Alfonso V under Alfonso (Spain; Aragon).

NAVARRRE

● **Alfonso**: see Alfonso I under Alfonso (Spain; Aragon).

PORTUGAL

● **Alfonso I–VI**: see Afonso I–VI under Afonso (Portugal).

SPAIN: ARAGON

● **Alfonso I**, byname ALFONSO THE BATTLE, Spanish ALFONSO EL BATALLADOR (b. c. 1073—d. September 1134), king of Aragon and of Navarre from 1104 to 1134.

Alfonso was the son of Sancho V Ramirez. He was persuaded by Alfonso VI of Leon and Castile to marry the latter's heiress, Urraca, widow of Raymond of Burgundy. In consequence, when Alfonso VI died (1109) the four Christian kingdoms were nominally united and Alfonso I took his father-in-law's imperial title. The union failed, however, because Leon and Castile felt hostility toward an Aragonese emperor; because Urraca disliked her second husband; and because Bernard, the French Cluniac archbishop of Toledo, wanted to see his protégé, Alfonso Ramirez (infant son of Urraca and her Burgundian first husband), on the imperial throne. At Bernard's prompting, the Pope declared the Aragonese marriage void, but Alfonso continued to be involved in civil strife in the central kingdom until he eventually gave up his claims in favour of his stepson after the death of Urraca (1126). Despite these embroilments, he achieved spectacular victories against the Moors, capturing Saragossa in 1118 and leading a spectacular military raid far into southern Andalusia in 1125. In his campaigns he received much help from the rulers of the counties north of the Pyrenees, resulting in the involvement of Aragon in the affairs of southern France. Alfonso was fatally wounded in battle at Fraga in 1134. Deeply religious, he bequeathed his kingdom to the Templars and the Hospitallers, but his former subjects refused to accept the donation, and the kingdoms eventually came under the control of the counts of Barcelona.

Alfonso II (b. 1152, Barcelona—d. 1196, Perpignan, Roussillon), count of Barcelona from 1162 and king of Aragon from 1164.

The son of Ramón Berenguer IV, Alfonso succeeded his father as count of Barcelona and his mother as ruler of Aragon, thus associating the two countries under the house of Barcelona—a union that was destined to be permanent. Aragonese involvement in France became steadily greater during Alfonso's reign. Nevertheless, the conquest of Teruel (1171) opened the way for the conquest of Valencia; and, in 1179, the pact of Cazorla with his ally, Alfonso VIII of Castile, fixed the future zones of reconquest for the two countries. In his will Alfonso followed the Spanish custom of dividing his kingdom; Provence was thus lost to the Aragonese crown.

● **Alfonso III**, byname ALFONSO THE LIBERAL, OF THE CANDID, Spanish ALFONSO EL LIBERAL, OF EL FRANCO (b. 1265—d. June 18, 1291, Barcelona), king of Aragon from 1285 to 1291, son of Peter III. A weak king, he was involved in an unsuccessful constitutional struggle with the Aragonese nobles. In 1287 he was compelled to grant the so-called "Privilegio de la Unión," which handed over a number of important royal prerogatives to baronial control. At Alfonso's death the crown passed to his brother James II, who had been king of Sicily (as James I) since 1285.

● **Alfonso IV**, byname ALFONSO THE KIND, Spanish ALFONSO EL BENIGNO (b. 1299—d. Jan. 24, 1336, Barcelona), king of Aragon from 1327 to 1336, son of James II. He was well-intentioned but weak. His reign was marked by a serious revolt in Sardinia, which led to war with Genoa, and by the establishment of diplomatic relations with the Moorish kingdoms of North Africa. The failure of the king to resist the efforts of his second wife to further the future of her sons at the expense of Alfonso's heir, Peter, led to serious political disturbances.

● **Alfonso V**, byname ALFONSO THE MAGNANIMOUS, Spanish ALFONSO EL MAGNÁNIMO (b. 1396—d. June 27, 1458, Naples), king of Aragon (1416–58) and king of Naples (as Alfonso I, 1442–58), whose military campaigns in Italy and elsewhere in the central Mediterranean made him one of the most famous

Alfonso V, bronze medal by Pisanello, 1448–49; in the Bargello, Florence
Alinari—Giraudon from Art Resource/EB Inc

men of his day. After conquering Naples, he transferred his court there.

Life. Alfonso was born and brought up in the brilliant Castilian court at Medina del Campo; but when he was 16, his father became king of Aragon, and he himself went to live there. Three years later (1415) he married his cousin María, the daughter of Henry III of Castile, but she produced no children, and they were separated for many years. The marriage was a failure and perhaps helps to explain Alfonso's reluctance to return to his peninsular kingdoms after he had conquered Naples, where he was encouraged to remain by his mistress, Lucrezia de Alagno.

He succeeded his father as king of Aragon in 1416 and, at the beginning of his reign, had political difficulties with both Catalans and Aragonese, because he retained some Castilian counsellors and deprived the *justicia*, the supreme law officer of Aragon, of his position.

From the moment of his accession, Alfonso continued the traditional Aragonese policy of Mediterranean expansion. Thus, in 1420 he set out with a fleet to pacify Sardinia and Sicily and to attack the Genoese possession of Corsica. The queen of Naples, Joan II, then sought his help against Louis III of Anjou and adopted him as her son and heir. Alfonso was received as a liberator in Naples on July 5, 1421; but the volatile character of the Queen, who soon afterward began to make overtures to Louis of Anjou, obliged Alfonso in 1423 to return to Catalonia to seek reinforcements.

After intervening in the internal politics of Castile to defend the interests of his brothers Henry and John in the near civil war that existed during the weak rule of John II, Alfonso set out again for Italy, from where, as it turned out, he was never to return. He was receiving tempting offers (1432) to intervene again in Naples and spent two years in Sicily preparing his fleet and army. His opportunity seemed to come in 1435, after the deaths of Louis III of Anjou and Queen Joan II, but while blockading the port of Gaeta, a key citadel from which to launch an attack on Naples, he was defeated off the island of Ponza by a Genoese squadron. Alfonso was captured, with many others, and sent as a prisoner to Genoa and then to Milan, whose duke, Filippo Maria Visconti, ruled both cities. Alfonso, however, charmed his captor into an alliance and then continued his fight to gain possession of Naples against the opposition of Venice, Florence, and the Pope. He took Naples on June 2, 1442, and transferred his court there permanently in 1443. It became a brilliant centre of art and culture, fed by the fertile interaction of Italian Renaissance and Spanish Gothic influences and forming a cultural bridge between the two peninsulas of the western Mediterranean.

Alfonso engaged in much diplomatic and military activity in Africa, the Balkans, and the eastern Mediterranean in order to protect

his commerce with the East and to share in the defense of Christendom against the Turks. He helped the Knights of St. John defend Rhodes; allied himself with Hungary (1444), with Serbia (1447), and with Abyssinia (1450); and fought against Egypt (1453–54). But he was not strong enough to prevent the fall of Constantinople to the Turks in 1453.

Meanwhile, his Spanish dominions were suffering from serious unrest, the result of social and economic tensions to which no solution could be found by his viceroys, his queen, Maria, and his brother John of Navarre. In Catalonia the *remensa*, the peasantry, were vigorously seeking to be freed from feudal dues and received some support from the crown. In Majorca a popular rising, which led to fighting between the capital of the island and the rural population, had to be crushed by troops that Alfonso sent from Naples. And in Barcelona a serious class struggle caused so many disturbances in the city that Alfonso reformed the city government, allowing public offices to be distributed by lot. Meanwhile, the sporadic war with Castile both impoverished the Kingdom of Aragon and deprived Alfonso and his family of their ancestral estates in Castile. Only Valencia, with its flourishing economy, remained unharmed by the general crisis. A restless, energetic ruler to the last, Alfonso was engaged in an assault upon Genoa, which had recently surrendered to the French, when death surprised him in Ovo Castle at Naples in June 1458. In the Kingdom of Naples he was succeeded by his illegitimate son, Ferrante, and in his other states by his brother John (King John II of Aragon), who had been king of Navarre since 1425.

Assessment. Alfonso was praised, respected, and admired by the writers of his own time and also by those of the next generation. The latter were still close enough to him to draw upon a living tradition but were free of the desire to flatter that affected his contemporaries. Among Alfonso's apologists were the Italian Humanist scholars Antonio Beccadelli, Aeneas Sylvius Piccolomini (Pope Pius II), Vespasiano da Bisticci, and Giovanni Pontano. They praised Alfonso for his Humanist education and for his love of books and fine arts, for his delight in hunting, dancing, tournaments, and good clothes, and for his charity, clemency, and deep religious faith. He has been regarded by some scholars as a brilliant Renaissance prince and a great sovereign, but, in general, modern Spanish historians are less enthusiastic about Alfonso and blame him for occupying himself with amorous adventures in Naples while neglecting his duties to his peninsular territories. (E.Sa.)

SPAIN: ASTURIAS AND LEON

• **Alfonso I**, byname ALFONSO THE CATHOLIC, Spanish ALFONSO EL CATÓLICO (b. 693?—d. 757, Cangas, Galicia), king of Asturias from 739 to 757, probably the son-in-law of the first Asturian king, Pelayo. The rebellion of the Berber garrisons in Islāmic Spain (741) and the civil strife there that followed gave him the opportunity to incorporate Galicia into his kingdom. He also campaigned far to the south of the Asturian mountains, but lack of manpower made it impossible to exert permanent

control on the plains and, in his time, a wide, largely uninhabited no-man's-land came into being between Asturias and the settled territories of the emirate of Córdoba.

• **Alfonso II**, byname ALFONSO THE CHASTE, Spanish ALFONSO EL CASTO (b. 759, Oviedo, Asturias—d. 842, Oviedo), king of Asturias from 791 to 842, the son of Fruela I. He had to face frequent and determined attacks by the armies of the emirate of Córdoba and was often defeated, but his doggedness saved Asturias from extinction. He built a new capital, Oviedo, on a strategic site in the mountains and set about giving the Asturian kingdom a national identity. He tried to enter into relations with Charlemagne, but although he seems to have failed to get Carolingian support, there are some traces of Frankish influence in Asturias. During Alfonso's reign the discovery of the supposed tomb of St. James the Apostle in Galicia made the kingdom the guardian of an important Christian shrine (Santiago de Compostela), and this, too, helped to give it a national identity.

• **Alfonso III**, byname ALFONSO THE GREAT, Spanish ALFONSO EL MAGNO (b. c. 838—d. Dec. 20, 910?, Zamora, Leon), king of Asturias from 866 to 910, son of Ordoño I.

Winning a contested succession, he moved his capital forward from Oviedo to the recently restored Roman city of León. Under him, Porto (Oporto) was occupied in 868, and Castile took shape around Burgos, drawing on his Basque allies. He claimed to be reviving the Visigothic monarchy, while making the church of St. James at Santiago de Compostela the shrine of the Christian kingdom. Alfonso's territorial advances were made possible by the convulsion of the Muslim emirate of Córdoba, in which Arab dominion was challenged by the Berber dissidents. For a time Córdoba itself was endangered, and the triumph of Alfonso was thought imminent. This did not occur, but by the end of the reign Alfonso III had occupied Coimbra, Zamora, and Burgos, settling refugees from the south.

• **Alfonso IV**, byname ALFONSO THE MONK, Spanish ALFONSO EL MONJE (d. 933), king of Leon and Asturias from c. 926 to c. 931, the son of Ordoño II and the successor of his uncle Fruela II. He became a monk, abdicated, and then thought better of it and tried to recover his throne. His short reign was, in consequence, one of political chaos, ending in about 931.

• **Alfonso V**, byname ALFONSO THE NOBLE, Spanish ALFONSO EL NOBLE (b. 994—d. 1028), king of Leon from 999 to 1028, son of Bermudo II. He came to the throne because the devastating campaigns of Almanzor (*see* Mañsūr, Abū 'Amir al-) had forced his father to accept Almanzor's de facto suzerainty over Leon. The Leonese were forced to take part in the Moorish campaign against the Catalans (1003) and to suffer other indignities and incursions. The political troubles continued until the fall of the caliphate (1031) relieved Leon of Islāmic pressure, but Alfonso was soon faced by the growing power of Sancho III of Pamplona (Navarre). His marriage (1023/24) to Sancho's daughter Urraca ended this threat, and, in the last years of his life, he was able to undertake the reconquest of the Portuguese territories lost during Almanzor's time. He was killed at the siege of Viseu.

SPAIN: CASTILE AND LEON

• **Alfonso I–V:** *see* Alfonso I–V under Alfonso (Spain: Asturias and Leon).

• **Alfonso VI**, byname ALFONSO THE BRAVE, Spanish ALFONSO EL BRAVO (b. before June 1040—d. 1109, Toledo, Castile), king of Leon (1065–70) and king of reunited Castile and Leon (1072–1109), who by 1077 had proclaimed himself "emperor of all Spain" (*im-*

perator totius Hispaniae). His oppression of his Muslim vassals led to the invasion of Spain by an Almoravid army from North Africa (1086). His name is also associated with the

Alfonso VI, portrait miniature from a manuscript, 12th century; in Santiago cathedral, Spain

Archivo Mas, Barcelona

national hero of Spain, Rodrigo Díaz de Vivar (El Cid), who was alternatively his enemy and indifferent supporter.

Alfonso was the second son of King Ferdinand I and his wife Sancha; he was educated by Raimundo, later the bishop of Palencia, and by Pedro Ansúrez, the count of Carrión. On his death in 1065, Ferdinand left to Alfonso the kingdom of Leon together with tribute paid by the Muslim kingdom of Toledo. These possessions aroused the envious hostility of Alfonso's elder brother, Sancho II, who had inherited the kingdom of Castile and the tribute of Saragossa. Alfonso was defeated by his brother in two battles; after the defeat at Llantada (1068) he managed to retain his kingdom, but after that at Golpejera (1072) he was captured and exiled, living for a short while at the court of his vassal Ma'mūn, the Muslim king of Toledo. Soon Alfonso's sister Urraca stirred up a rebellion in Leon, and Sancho besieged her in the walled city of Zamora. During the siege, he was killed, perhaps at Urraca's instigation. She was clearly on Alfonso's side, and some modern historians have even suggested that they had an incestuous relationship.

With Sancho's death, Alfonso recovered his own kingdom of Leon and inherited (1072) that of Castile. He also occupied Galicia, which Sancho had kept from their younger brother García; Alfonso kept García in prison until his death. A late story, in which it is alleged that Alfonso took an oath in St. Gadea's Church, Burgos, that he had had no share in Sancho's murder, probably reflects Castilian reluctance to accept him as king.

Alfonso's reign now entered on a period of success. He seized the Rioja and the Basque provinces and received the feudal homage of Sancho Ramírez for the region of Navarre to the north of the Ebro River. By 1077 he had assumed the title *imperator totius Hispaniae*, in which role other Christian kings accepted him. He then began the conquest of Toledo

and, after a long siege, occupied it in May 1085. This was a vital conquest, which recovered for Christian Spain one of the most important historical, strategic, and cultural centres of the peninsula, one that had been in the possession of the Muslims since the early 8th century.

During this period Alfonso regularly exacted *parias*, heavy financial tributes, from the Muslim *ṣāʿifah* kingdoms in return for protection against their other enemies. By thus depriving them of their wealth, he hoped to weaken them so that they would eventually cede their independence without fighting. As a result of his exactions, Christian Spain was flooded with Muslim gold, which was spent on warfare and donations to shrines, churches, and monasteries. The demand for tribute caused the *ṣāʿifah* kings to tax their subjects heavily, producing popular discontent and disturbances and contributing to the weakness that caused the surrender of Toledo. The Muslim ruler al-Mu'tamid of Seville took a desperate decision and called for the help of Yūsuf ibn Tāshufīn, the Almoravid (Berber) *amīr* of North Africa, and his Saharan tribes. The Amīr disembarked in Algeciras at the end of July 1086 and a few months later, on October 23 at Zallāqah, near Badajoz, inflicted a terrible defeat on Alfonso VI. Alfonso appealed for help to the rest of Christendom, and a small crusade was organized as a result; the crusaders did not reach Alfonso's lands but wasted their energies and resources in an unsuccessful siege of the Muslim outpost of Tudela.

The defeat at Zallāqah seriously lessened Alfonso's influence over the *ṣāʿifah* kingdoms. It also led to a reconciliation with Rodrigo Díaz de Vivar, El Cid. Their relationship had been difficult from the start, because El Cid had taken a prominent part in the campaigns of Sancho against Alfonso; although El Cid at first attended Alfonso's court, suspicions deepened, and since 1081 he had been in the service of the Muslim king of Saragossa. Alfonso entrusted El Cid with the occupation and defense of eastern Spain, and Rodrigo carried out this task with great success. Between 1086 and 1109 Alfonso suffered constant defeat by the Almoravids; in the last battle, that of Uclés in 1108, he lost his only son, Sancho. It was characteristic of his indomitable spirit that he at once arranged for his daughter, Urraca, to marry Alfonso I of Aragon so that the war against the Almoravids should be continued after his death, even though it meant that Leon and Castile would be ruled by an Aragonese prince.

Though his reign was politically unsuccessful, Alfonso VI carried out an important cultural task by Europeanizing his dominions. Alfonso married Constance of Burgundy, and influences from across the Pyrenees showed themselves in the introduction of the Romanesque style in art, the adoption of the Roman instead of the Mozarabic liturgy, the replacement of Visigothic by Carolingian script, and the energetic support that Alfonso gave to Cluniac monasticism, as well as in his reconstruction and safeguarding of the pilgrim road to Santiago.

(E.Sa.)

BIBLIOGRAPHY. The most important source for Alfonso VI and his age is Ramón Menéndez Pidal, *La España del Cid*, 7th ed., 2 vol. (1969; Eng. trans. of 1st ed., *The Cid and His Spain*, 1934).

• **Alfonso VII**, byname ALFONSO THE EMPEROR, Spanish ALFONSO EL EMPERADOR (b. 1104?—d. August 1157, Fresneda, Castile), king of Leon and Castile from 1126 to 1157, son of Raymond of Burgundy and the grandson of Alfonso VI, whose imperial title he assumed. Though his reign saw the apogee of the imperial idea in medieval Spain and

though he won notable victories against the Moors, he remains a somewhat hazy figure.

His childhood was complicated by the struggle between his mother Urraca and her second husband, Alfonso I of Aragon, for control of Castile and Leon. Only on Urraca's death (1126) did his stepfather finally relinquish his claims. Alfonso was then formally accepted as emperor by the kings of Aragon and Pamplona (Navarre), by the count of Barcelona, and by various Hispano-Moorish rulers. His capture of Almería (1147) from the Moors won him renown, as did other victories, but in the end these led to little expansion of territory. Almería was lost again in 1157 and Córdoba remained in his hands for only three years. In 1146 a new invasion of North African fanatics, the Almohads, began. Alfonso now allied himself with the Almoravids and devoted the rest of his life to a series of campaigns to check Almohad expansion in southern Spain.

Despite the importance of the imperial idea at this time, peninsular fractionalist tendencies were by no means dormant. Alfonso was unable to prevent the establishment of Portugal as an independent kingdom (1140) and, in his will, he himself divided his realm, as was the Spanish custom, between his two sons, Sancho III of Castile and Ferdinand II of Leon. This act finally destroyed the concept of empire in medieval Spain.

• **Alfonso VIII**, byname EL DE LAS NAVAS (Spanish: He of Las Navas) (b. 1155—d. Oct. 6, 1214, Burgos, Castile), king of Castile from 1158, son of Sancho III, whom he succeeded when three years old.

Before Alfonso came of age his reign was troubled by internal strife and the intervention of the kingdom of Navarre in Castilian affairs. Throughout his reign he maintained a close alliance with the kingdom of Aragon, and in 1179 he concluded the Pact of Cazorla, which settled the future line of demarcation between Castile and Aragon when the reconquest of Moorish Spain was completed. From 1172 to 1212 he was engaged in resistance to the Moorish Almohad invaders, who defeated him in 1195. In the same year the kings of Leon and Navarre invaded Castile, but Alfonso defeated them with the aid of King Peter II of Aragon. In 1212 Alfonso secured a great victory at Las Navas de Tolosa over the Almohad sultan and thereby broke Almohad power in Spain.

• **Alfonso IX** (b. 1171, Zamora, Leon—d. Sept. 24, 1230, Villanueva de Sarria, Galicia), king of Leon from 1188 to 1230, son of Ferdinand II of Leon and cousin of Alfonso VIII of Castile (next to whom he is numbered as a junior member of the family). A forceful personality, Alfonso IX was determined to recover Leonese territory lost to Castile; and, despite the fact that he had done homage to Alfonso VIII, he did not hesitate to ally himself with the Almohads to further this end. As a result, his kingdom was placed under papal interdiction, and he was finally compelled to marry the Castilian king's eldest daughter. He refused, however, to join his father-in-law in the crusade against the Almohads in 1212 unless the lost lands were first restored by Castile. This was not done and the Leonese army was, therefore, absent from Las Navas de Tolosa. Nevertheless, operating on his own, Alfonso IX won important victories beyond the southern frontiers of Leon, taking Cáceres (1227) and Mérida and Badajoz (1230) from the Almohads. These victories opened the road for a future reconquest of Seville.

• **Alfonso X**, byname ALFONSO THE WISE, Spanish ALFONSO EL SABIO (b. Nov. 23, 1221, Burgos, Castile—d. April 4, 1284, Seville), king of Castile and Leon from 1252 to 1284.

His father, Ferdinand III, conquered Andalusia and imposed tribute on the remaining Muslim states in Spain—Murcia and Granada.

His mother, Beatrice, was granddaughter of the Holy Roman emperor Frederick I. Alfonso, already known as a scholar, became king in 1252. He had many scholars in his travelling court, and he was an active participant in their writing and editing. Some were experts on Roman law, which Alfonso hoped to make the basis of a uniform code for his lands. The court, gifts to friends, and foreign intrigue proved expensive, and Alfonso taxed heavily.

Alfonso crushed a Muslim revolt in 1252, and a revolt by nobles in 1254. Morocco, Granada, and Murcia invaded in 1264, but Alfonso won with Aragonese help, and annexed Murcia. In 1272, a revolt, and withdrawal to Granada, by nobles forced him to confirm local privileges.

In 1273 Alfonso founded, and granted privileges to, the Mesta, a guild of migratory shepherds.

Alfonso claimed many foreign titles, notably that of Holy Roman emperor in 1256. In 1257, bribes won him four electoral votes for emperor to three for Richard of Cornwall, but Richard, unlike Alfonso, could go to Germany. In 1275 Richard died, and Alfonso went to France to appeal to Pope Gregory X, who persuaded him to renounce his claim.

While Alfonso was in France, Morocco and Granada invaded Castile. Ferdinand, Alfonso's eldest son, was killed in the fighting. Sancho, Alfonso's second son, became a hero in defeating the invaders, and proclaimed himself heir, disregarding Ferdinand's sons, who were nephews of the French king. Alfonso recognized Sancho's claim in 1278, but, under French pressure, became ambiguous in 1281. Taking advantage of grievances against Alfonso, Sancho declared himself regent. Towns and nobles rose against Alfonso, who had to take refuge in Seville. Some of Sancho's followers deserted, but, after Alfonso died, Sancho took Seville and became King Sancho IV.

Alfonso's court scholars wrote mostly in Castilian Spanish, which they made a literary language by regularizing the syntax and by borrowing—and defining—words for concepts not previously discussed. In their *Primera crónica general*, they tried to determine historical facts from chronicle, folklore, and Arabic sources. Less factual was their *Gran e general estoria*, a world history, with extensive translations from the Old Testament. The *Tablas Alfonsíes* were planetary tables, based on an Arabic source but updated by observations at Toledo 1262–72. *Siete partidas* was the most important law code. It was based on Roman law, and contained discourses on manners and morals, and an idea of the king and his people as a corporation—superior to feudal arrangements—with the king as agent of both God and the people. After Alfonso's death, *Siete partidas* was proclaimed the law of all Castile and Leon in 1348, and the language of Alfonso's court evolved into modern Castilian Spanish.

• **Alfonso XI**, byname ALFONSO THE JUST, Spanish ALFONSO EL JUSTICIERO (b. 1311, Salamanca, Leon—d. March 26, 1350, Gibraltar), king of Castile and Leon from 1312, who succeeded his father, Ferdinand IV, when he was only a year old.

His minority was marked by violent strife between factions of nobles, but when he came of age, in 1325, he restored order with unprecedented vigour. He gave new powers to the municipalities and to the Cortes, in exchange for their support against the nobles, and furthered the power of the crown by choosing officials without aristocratic affiliations. He then turned his attention to the Marinid kings of Morocco, who had seized Gibraltar and routed the Castilian fleet at Algeciras in 1340. With the Portuguese, he defeated the invaders at Río Salado in 1340 and recaptured Algeciras in 1344.

Alfonso XI promulgated important administrative and legal reforms in the ordinances of Alcalá de Henares in 1348. Alfonso was assiduously courted by both France and England, who wished for an alliance that would give them the support of his powerful fleet, but he avoided committing himself to either party.

SPAIN

• **Alfonso I–XI:** *see* Alfonso I–XI *under* Alfonso (Spain: Castile and Leon).

• **Alfonso XII** (b. Nov. 28, 1857, Madrid—d. Nov. 25, 1885, Madrid), Spanish king whose short reign (1874–85) gave rise to hopes for a constitutional monarchy in Spain.

The eldest surviving son of Queen Isabella II and, presumably, her consort, the Duque de Cádiz, Alfonso accompanied his mother into exile following her deposition by the revolution of September 1868. He received his education at the Theresianum in Vienna and at the Royal Military College, Sandhurst, in England. Isabella abdicated her rights in his favour in June 1870, but it was not until four years later (Dec. 29, 1874) that Alfonso was proclaimed king of Spain. He returned to his country early in January of the following year.

For most of Alfonso's reign Spain enjoyed an unaccustomed tranquillity. The pattern of political life was determined by Antonio Cánovas del Castillo, prime minister from 1875 to 1881 and again from January 1884. The two most urgent problems—ending the civil war unleashed by the Carlists, the partisans of the successors to the Spanish throne in the male line, and drafting the constitution—were both settled in 1876. In addition, the Convention of Zanjón established peace in Cuba. In January 1878 Alfonso married María de las Mercedes, daughter of the Duc de Montpensier. She died six months later and the following year the King married a daughter of the archduke Charles Ferdinand of Austria, María Cristina, by whom he had two daughters and a son, who became Alfonso XIII.

Although politically inexperienced, Alfonso XII demonstrated great natural tact and sound judgment, qualities that gave rise to hope that the monarchy would not suffer if the democratic constitution enacted in 1876 were fully implemented. Attempts on the King's life (October 1878 and December 1879) and a military pronunciamiento against the regime (1883) were not indicative of any general discontent with the restored monarchy; on the contrary, Alfonso enjoyed considerable popularity, and his early death from tuberculosis was a great disappointment to those who looked forward to a constitutional monarchy in Spain.

• **Alfonso XIII** (b. May 17, 1886, Madrid—d. Feb. 28, 1941, Rome), Spanish king (1886–1931) who by seeking to enhance the power of the monarchy at the expense of Parliament hastened his own deposition by advocates of the Second Republic.

The posthumous son of Alfonso XII, Alfonso XIII was immediately proclaimed king under the regency of his mother, María Cristina. Though lively and intelligent, he was raised in an ultraclerical and reactionary atmosphere by his dotting mother. He reacted early against the boredom of court life and began his lifelong attachment to the Spanish army. In 1902, on his 16th birthday, he assumed full authority as king.

Alfonso relished his position of authority. He continued the system of alternating Conservative and Liberal governments (based on continued elections), but he increasingly intervened in politics in order to rotate governments. Political instability was the result; 33 governments were formed in Spain between 1902 and 1923, and the parliamentary system was steadily discredited. Alfonso's popularity also suffered, and the notorious attempt on

his life and that of his bride, Victoria Eugenia of Battenberg, on their wedding day (May 31, 1906) was followed by a constant succession of plots to assassinate him. His great personal courage in the face of these attacks, however, won him considerable admiration.

Alfonso's position worsened after the failure of the government of Antonio Maura (1909); the last hope for the parliamentary regime seemed extinguished. Although his conduct during World War I was irreproachable (he observed a scrupulous neutrality and rendered great service to humanitarian causes), in the postwar period he began to move toward a system of more personal rule, even seeking a means to rid himself of Parliament. He intervened directly in the Moroccan War in 1921 with such disastrous effect that a subsequent commission of inquiry placed the blame squarely on him. A week before the report was to be published, however, Alfonso was rescued from a humiliating situation by a coup d'état (Sept. 13, 1923) led by Gen. Miguel Primo de Rivera.

By directly associating himself with the overthrow of the parliamentary regime, however, and linking his fortunes to the dictatorship of Primo de Rivera, Alfonso jeopardized the existence of the Spanish monarchy. When Primo de Rivera fell from power in January 1930, a temporary government under Gen. Dámaso Berenguer was called on to save the King. Alfonso tried various methods to bring about a return to a constitutional regime without the risk of elections. Eventually, he agreed to hold municipal elections (April 1931), which, at least in the important towns, resulted in a landslide for the Republican parties. The victors demanded the King's abdication; the army withdrew its support and Alfonso, though refusing to abdicate, was forced to leave Spain (April 14, 1931).

Alfonso never returned. Gen. Francisco Franco reinstated him as a Spanish citizen and restored his property (confiscated in 1932), but he eventually abdicated his rights to his third son, Don Juan.

Alfred, also spelled AELFRED, byname ALFRED THE GREAT (b. 849—d. 899), king of Wessex (871–899), a Saxon kingdom in southwestern England. He prevented England from falling to the Danes and promoted learning and literacy. Compilation of the Anglo-Saxon Chronicle began during his reign, c. 890.

When he was born, it must have seemed unlikely that Alfred would become king, since he had four older brothers; he said that he never desired royal power. Perhaps a scholar's life would have contented him. His mother early aroused his interest in English poetry, and from his boyhood he also hankered after Latin learning, possibly stimulated by visits to Rome in 853 and 855. It is possible also that he was aware of and admired the great Frankish king Charlemagne, who had at the beginning of the century revived learning in his realm. Alfred had no opportunity to acquire the education he sought, however, until much later in life.

Alfred the Great, Anglo-Saxon coin, 9th century; in the British Museum

He probably received the education in military arts normal for a young man of rank. He first appeared on active service in 868, when he and his brother, King Aethelred (Ethelred) I, went to help Burgred of Mercia (the kingdom between the Thames and the Humber) against a great Danish army that had landed in East Anglia in 865 and taken possession of Northumbria in 867. The Danes refused to give battle, and peace was made. In this year Alfred married Ealhswith, descended through her mother from Mercian kings. Late in 871, the Danes invaded Wessex, and Aethelred and Alfred fought several battles with them. Aethelred died in 871 and Alfred succeeded him. After an unsuccessful battle at Wilton he made peace. It was probably the quality of the West Saxon resistance that discouraged Danish attacks for five years.

In 876 the Danes again advanced on Wessex; they retired in 877 having accomplished little, but a surprise attack in January 878 came near to success. The Danes established themselves at Chippenham, and the West Saxons submitted "except King Alfred." He harassed the Danes from a fort in the Somerset marshes, and until seven weeks after Easter he secretly assembled an army, which defeated them at the Battle of Edington. They surrendered, and their king, Guthrum, was baptized, Alfred standing as sponsor; the following year they settled in East Anglia.

Wessex was never again in such danger. Alfred had a respite from fighting until 885, when he repelled an invasion of Kent by a Danish army, supported by the East Anglian

Danes. In 886 he took the offensive and captured London, a success that brought all the English not under Danish rule to accept him as king. The possession of London also made possible the reconquest of the Danish territories in his son's reign, and Alfred may have been preparing for this, though he could make no further advance himself. He had to meet a serious attack by a large Danish force from the European continent in 892, and it was not until 896 that it gave up the struggle.

The failure of the Danes to make any more advances against Alfred was largely a result of the defensive measures he undertook during the war. Old forts were strengthened and new ones built at strategic sites, and arrangements were made for their continual manning. Alfred reorganized his army and used ships against the invaders as early as 875. Later he had larger ships built to his own design for use against the coastal raids that continued even after 896. Wise diplomacy also helped Alfred's defense. He maintained friendly relations with Mercia and Wales; Welsh rulers sought his support and supplied some troops for his army in 893.

Alfred succeeded in government as well as at war. He was a wise administrator, organizing his finances and the service due from his thanes (noble followers). He scrutinized the administration of justice and took steps to ensure the protection of the weak from oppression by ignorant or corrupt judges. He promulgated an important code of laws, after studying the principles of lawgiving in the Book of Exodus and the codes of Aethelbert of Kent, Ine of Wessex (688–694), and Offa of Mercia (757–796), again with special attention to the protection of the weak and dependent. While avoiding unnecessary changes in custom, he limited the practice of the blood feud and imposed heavy penalties for breach of oath or pledge.

Alfred is most exceptional, however, not for his generalship or his administration but for his attitude toward learning. He shared the contemporary view that Viking raids were a divine punishment for the people's sins, and he attributed these to the decline of learning, for only through learning could men acquire wisdom and live in accordance with God's will. Hence, in the lull from attack between 878 and 885, he invited scholars to his court from Mercia, Wales, and the European continent. He learned Latin himself and began to translate Latin books into English in 887. He directed that all young freemen of adequate means must learn to read English, and, by his own translations and those of his helpers, he made available English versions of "those books most necessary for all men to know," books that would lead them to wisdom and virtue. The *Ecclesiastical History of the English People*, by the English historian Bede, and the *Seven Books of Histories Against the Pagans*, by Paulus Orosius, a 5th-century theologian—neither of which was translated by Alfred himself, though they have been credited to him—revealed the divine purpose in history. Alfred's translation of the *Pastoral Care* of St. Gregory I, the great 6th-century pope, provided a manual for priests in the instruction of their flocks, and a translation by Bishop Werferth of Gregory's *Dialogues* supplied edifying reading on holy men. Alfred's rendering of the *Soliloquies* of the 5th-century theologian St. Augustine of Hippo, to which he added material from other works of the Fathers of the Church, discussed problems concerning faith and reason and the nature of eternal life. This translation deserves to be studied in its own right, as does his rendering of Boethius' *Consolation of Philosophy*. In considering what is true happiness and the relation of providence to faith and of predes-

tinuation to free will, Alfred does not fully accept Boethius' position but depends more on the early Fathers. In both works, additions include parallels from contemporary conditions, sometimes revealing his views on the social order and the duties of kingship. Alfred wrote for the benefit of his people, but he was also deeply interested in theological problems for their own sake and commissioned the first of the translations, Gregory's *Dialogues*, "that in the midst of earthly troubles he might sometimes think of heavenly things." He may also have done a translation of the first 50 psalms. Though not Alfred's work, the Anglo-Saxon Chronicle, one of the greatest sources of information about Saxon England, which began to be circulated about 890, may have its origin in the intellectual interests awakened by the revival of learning under him. His reign also saw activity in building and in art, and foreign craftsmen were attracted to his court.

In one of his endeavours, however, Alfred had little success; he tried to revive monasticism, founding a monastery and a nunnery, but there was little enthusiasm in England for the monastic life until after the revivals on the European continent in the next century.

Alfred, alone of Anglo-Saxon kings, inspired a full-length biography, written in 893, by the Welsh scholar Asser. This work contains much valuable information, and it reveals that Alfred laboured throughout under the burden of recurrent, painful illness; and beneath Asser's rhetoric can be seen a man of attractive character, full of compassion, able to inspire affection, and intensely conscious of the responsibilities of kingly office. This picture is confirmed by Alfred's laws and writings.

Alfred was never forgotten: his memory lived on through the Middle Ages and in legend as that of a king who won victory in apparently hopeless circumstances and as a wise lawgiver. Some of his works were copied as late as the 12th century. Modern studies have increased knowledge of him but have not altered in its essentials the medieval conception of a great king.

(D.W.)

near Athelney, Somerset, Eng., where Alfred the Great took refuge from the Danes in 878. Its design shows strong Byzantine influence.

Alfvén, Hannes, in full HANNES OLOF GÖSTA ALFVÉN (b. May 30, 1908, Norrköping, Sweden—d. April 2, 1995, Djursholm), astrophysicist and winner, with Louis Néel of France, of the Nobel Prize for Physics in 1970 for his essential contributions in founding plasma physics—the study of plasmas (ionized gases).

Alfvén was educated at Uppsala University and in 1940 joined the staff of the Royal Institute of Technology, Stockholm. During the late 1930s and early '40s he made remarkable contributions to space physics, including the theorem of frozen-in flux, according to which under certain conditions a plasma is bound to the magnetic lines of flux that pass through it. Alfvén later used the concept to explain the origin of cosmic rays.

In 1939 Alfvén published his theory of magnetic storms and auroral displays in the atmosphere, which immensely influenced the modern theory of the magnetosphere (the region of the Earth's magnetic field). He discovered a widely used mathematical approximation by which the complex spiral motion of a charged particle in a magnetic field can be easily calculated. Magnetohydrodynamics (MHD), the study of plasmas in magnetic fields, was largely pioneered by Alfvén, and his work has been acknowledged as fundamental to attempts to control nuclear fusion.

After numerous disagreements with the Swedish government, Alfvén obtained a position (1967) with the University of California, San Diego. Later he divided his teaching time between the Royal Institute in Oslo and the University of California.

Alfvén was an early supporter of "plasma cosmology," a concept that challenges the big-bang model of the origin of the universe. Those who support the theory of plasma cosmology hold that the universe had no beginning (and has no foreseeable end) and that plasma—with its electric and magnetic forces—has done more to organize matter in the universe into star systems and other large observed structures than has the force of gravity. Much of Alfvén's early research was included in his *Cosmical Electrodynamics* (1950). He also wrote *On the Origin of the Solar System* (1954), *Worlds-Antiworlds* (1966), and *Cosmic Plasma* (1981).

alga, plural ALGAE, or ALGAS, any of a group of chiefly aquatic, nonvascular, photosynthetic, and eucaryotic organisms of the kingdom Protista. They range in size from one-celled flagellates measuring as little as 1 micron (one millionth of a metre) to the giant kelp reaching a length of 60 m (200 feet). Some authorities continue to classify the algae as plants or plantlike organisms, although they lack true leaves, stems, roots, and vascular systems, a feature they share with bryophytes (*compare* bryophyte).

A brief treatment of algae follows. For full treatment, see MACROPAEDIA: Algae.

Algae may have from one to a few cells or may have tissuelike aggregations of cells. Filamentous forms may be branched (e.g., *Sticheoclonium*) or unbranched (e.g., *Spirogyra*). Some algae are single-celled flagellates (e.g., *Oochromonas*), while others (e.g., *Scenedesmus*) aggregate into colonies. *Codium*, the green seaweed, has a tissuelike appearance but is not separated into different cells. Although primarily aquatic, algae are ubiquitous, inhabiting regions from the forests of the temperate zones to the Arctic tundra. Some varieties live in soil and withstand long periods without water; others live in snow, and a few species thrive in hot springs.

Algae share such eucaryotic cellular features as a nucleus and membrane-bound vacuoles and organelles (such as mitochondria). The majority of algae are aerobic, requiring oxy-

gen for their life processes. Photosynthesis is carried out using the various chloroplast molecules, such as chlorophyll, carotenoids, and phycobiliproteins. Ninety percent of all photosynthesis on the Earth is carried out by algae, and it is believed that they played an important role in creating the Earth's oxygen-rich atmosphere early in the planet's history.

Planktonic algae are an essential link in the food chain in the oceans, and all higher aquatic life-forms ultimately depend on it. In addition, algae have been used as feed for livestock and as food for human consumption since prehistoric times.

Algae is used for a wide range of commercial purposes. Among its products is a form of gelose (e.g., agar) that is produced by more than 70 species of red algae. Agar is used in the canning of fish and the packing of cooked fish, to size fabric, in the manufacture of film and high-grade adhesives, and in soups, sauces, jellies, ice creams, and icings. The uses of carrageenan extracts (a product of Irish moss) parallel those of agar and also include the making of sodium, potassium, or calcium salts. Algenic acids, a constituent of brown algae, produce alkali salts that are spun like silk to make threads.

Algae can reproduce vegetatively (through cell division or fragmentation), asexually (through the release of motile zoospores or the production of other spore forms), or sexually. Sexual reproduction usually occurs at times of stress in the life cycle (i.e., at the end of the growing season or during unfavourable environmental conditions).

Algardi, Alessandro (b. 1595, Bologna, Papal States [Italy]—d. June 10, 1654, Rome), after Bernini, the most important Roman sculptor of the 17th century working in the Baroque style.

Algardi was trained under Lodovico Carracci. After a short period of activity in Mantua (1622), he moved to Rome (1625), where he designed the stucco decorations in San Silvestro al Quirinale and gained some success as a restorer of classical sculptures. With the monument of Cardinal Millini (d. 1629) in Santa Maria del Popolo, the Frangipani monument in San Marcello al Corso, and the bust of Cardinal Laudivio Zacchia (Berlin), Algardi emerged as the principal rival of Bernini in the field of portrait sculpture. Lacking Bernini's dynamic vitality and penetrating characterization, Algardi's portraits were appreciated for their sobriety and surface realism.

"Meeting of Attila and Pope Leo," colossal marble relief by Alessandro Algardi, 1646–53; in St. Peter's, Rome

Ainari—Anderson from Art Resource/EB Inc

After the election of Pope Innocent X (1644), Algardi superseded Bernini in papal favour. Between this date and his death he produced some of his most celebrated works, among them the seated statue of the pope now in the Palazzo dei Conservatori (1645) and a colossal marble relief of the "Meeting of Attila and Pope Leo" in St. Peter's (1646–53), which influenced the development and popularization of illusionistic reliefs. At this time he also designed the Villa Doria Pamphili and a fountain in the Cortile di San Damaso of the Vatican.

Algardi's style was less ebullient and pictorial than Bernini's, and, even in such typically Baroque works as the tomb of Pope Leo XI in St. Peter's (1634–52) and the high altar of San Paolo at Bologna (1641), the restraining influence of the antique is strongly felt.

Algarotti, Francesco (b. Dec. 11, 1712, Venice [Italy]—d. May 3, 1764, Pisa), connoisseur of the arts and sciences, esteemed by the philosophers of the Enlightenment for his wide knowledge and elegant presentation of advanced ideas.

Educated at Rome, Bologna, and Florence, Algarotti went to Paris at the age of 20. There his urbanity, his physical beauty, and his versatile intelligence promptly made an impression in intellectual circles. A year later

Algarotti, detail of an engraving by Giuseppe Dala

By courtesy of the Civici Musei, Venice, Italy

he wrote *Il Newtonianismo per le dame* (1737; "Newtonianism for Ladies"), a popular exposition of Newtonian optics. Following a visit to Russia in 1739, he received an invitation to Prussia from Frederick the Great, which led to his staying more than nine years in Germany. Ill health eventually obliged him to return to Italy, first to Venice and then to Pisa. A monument on his tomb was inscribed with "Algarottus non omnis" ("[Here lies] Algarotti [but] not all"). Algarotti's writings include several studies on classical themes and a number of stimulating essays on the subjects of architecture (1753), the opera (1755), and painting (1762).

Algarve, historical province of southern Portugal, corresponding to the modern administrative *distrito* of Faro, bounded by the Atlantic Ocean (south and west) and the lower Guadiana River (east). Much of the interior upland region is of low productivity and is sparsely populated; the fertile coastal lowland is more densely inhabited.

The Phoenicians established bases in the area, and the Romans later conquered it; Visigoths ruled the region until Muslims took control in the early 8th century. After nearly five centuries of Muslim rule, Algarve was taken into the Portuguese kingdom in 1189. Algarve (Arabic: al-Gharb, meaning "the west") remains Moorish in appearance.

The economy is based on agriculture (corn [maize], figs, olives, almonds, grapes, pomegranates, and carobs). Fishing (tuna, anchovies, mackerel, and sardines) is also important; industries include the processing of fish, cork, and wine, as well as mining. In

recent years tourism in the Algarve region has increased greatly. Prince Henry the Navigator established his school of navigation at Sagres Point about 1418.

Harvesting in the coastal area of Algarve, Portugal
Maurice Landre—APA

After Portugal granted independence to Angola and Mozambique in the 1970s, about 500,000 *retornados* ("returnees") fled to Portugal. The Portuguese government, with assistance from the United States, subsidized housing in Algarve's hotels for the *retornados*, at costs that nearly collapsed the economy. These problems, however, did not hamper development of the tourist industry.

algebra, branch of mathematics in which the procedures of arithmetic are generalized and applied to variable quantities, as well as to specific numbers. To the layperson, algebra means elementary algebra, in which one learns to calculate with variables instead of just the numbers of arithmetic and to solve polynomial equations. To the professional mathematician, however, as well as to increasing numbers of scientists in other fields, algebra means rather what is called modern, higher, or abstract, algebra—the study of abstract mathematical structures in which there are operations that have the properties of addition and multiplication.

A brief treatment of algebra follows. For full treatment, see MACROPAEDIA: Algebra.

Essential to both elementary and higher algebra is the fact that the calculations should always involve only a finite number of quantities and end after a finite number of steps; in other words, processes in which the answers are obtained "in the limit" generally do not belong to algebra. Thus

$$1 + x + x^2 + x^3 + \cdots + x^n = \frac{1 - x^{n+1}}{1 - x}$$

is algebra, but

$$1 + x + x^2 + x^3 + \cdots + x^n + \cdots = \frac{1}{1 - x}$$

is not.

A second characteristic of algebra is its abstractness. Even in elementary algebra, calculations are made not with numbers but with letters that represent numbers. In higher algebra the letters may represent much more general objects, and the system of calculation is itself an abstraction of systems having similar properties.

The demands placed on algebra by other branches of mathematics have been the richest and most significant source of new results in algebra, while, at the same time, the axiomatic, abstract algebraic viewpoint has simplified and clarified work in other fields, providing techniques leading both to new results and to unexpected connections between work in widely separated fields. This "algebraiza-

tion" of mathematics has been one of the most characteristic features of 20th-century mathematics. In this way the influence of algebra has actually been far greater than its results. At the same time, modern algebra has brought a clearer understanding of the processes of elementary algebra and has enabled mathematicians to gain an understanding of the principles that underlie the calculations.

The basic task of elementary algebra is the solution of polynomial, *i.e.*, "algebraic," equations and the stepwise introduction of new types of numbers—negative, real, and complex—to use in solving them. Determinants and matrices are devices for facilitating the solution of simultaneous equations and thus have their place. The quadratic formula is the explicit solution of the quadratic equation, and so also merits attention.

Permutations and combinations (typical problem: in how many ways can six men choose their wives from among six women, assuming no bigamy) are really elementary probability theory, but they use only algebraic arguments and the formulas are occasionally useful—the binomial coefficients, for instance. Exponentials and logarithms, on the other hand, are certainly not algebra, since they involve passage to the limit in their definition. Of course, the emphasis in elementary algebra is not on the precise definition of these functions but rather on the formal rules for operating with them, such calculation with formal rules being universally interpreted as "algebra."

Modern algebra evolved from elementary algebra in a series of jumps beginning essentially with the work of Évariste Galois in 1830. It includes all of elementary algebra and a great deal more, but in an extensively generalized form; each topic of elementary algebra is thus viewable as the starting point of one of the theories of modern algebra. The principle abstract objects of study are groups, rings, fields, vector spaces, and algebras. Groups have one operation (called addition or multiplication); rings have two; fields are commutative rings in which one can divide; vector spaces are additive groups in which there is a scalar multiplication by elements of some field; algebras (sometimes called linear algebras) are vector spaces with a multiplication law defined.

The theory of rings came from study of the formal properties of integers and polynomials. Fields arose from the attempts to provide solutions for algebraic equations. The proof that the equation of fifth degree could not be solved by a formula analogous to the quadratic formula gave rise to group theory. Finally, the solution of simultaneous linear equations in elementary algebra led directly to the theory of vector spaces and matrices; the square $n \times n$ matrices themselves give one of the most important examples of an algebra.

Finally, a word should be said about some of the applications of algebra to sciences other than mathematics. In theoretical physics, the theory of groups and their representations has played an important part in the development of quantum theory, particularly in connection with solid-state physics. The theory of Boolean algebras has been widely used in the design of computing machines. In the social sciences, psychology and economics are finding use for matrices and linear algebra in what is called linear programming. The introduction of algebra into other disciplines has stimulated the further development of algebra itself.

algebraic equation, statement of the equality of two expressions formulated by applying to a set of variables the algebraic operations, namely, addition, subtraction, multiplication, division, raising to a power, and extraction of a root. Equations that involve nonalgebraic

operations, such as the evaluation of logarithms or trigonometric functions, are said to be transcendental.

The solution of an algebraic equation is the process of finding a number or set of numbers that, if substituted for the variables in the equation, reduce it to an identity. Such a number is called a root (*q.v.*) of the equation. *See also* Diophantine equation; linear equation; quadratic equation.

algebraic geometry, the study of geometric objects by means of algebra.

A brief treatment of algebraic geometry follows. For full treatment, *see* MACROPAEDIA: Geometry: *Algebraic geometry*.

A Babylonian record of about 1700 BC describes a problem about a rectangle (a geometric object) and involves unknown numbers; it is, thus, an example of algebraic geometry. The Greek mathematicians of classical times had the problem: to construct the edge of a cube that shall have twice the volume of a given cube. Calling the edge of the given cube a and the edge of the sought cube x , we would write $x^3 = 2a^3$. Hippocrates of Chios (*c.* 430 BC) reformulated the problem as one of finding x and y such that $a/x = x/y = y/2a$. Menaechmus (*c.* 350 BC) considered the locus in a rectangular coordinate system of the points (x,y) such that $x^2 = ay$ and similarly of the points (x,y) such that $xy = 2a^2$, recognized the first as a parabola and the second as a hyperbola, and thus found x,y from the intersection of these curves.

The 17th-century French mathematicians René Descartes and Pierre de Fermat studied the conic sections and knew that the points (x,y) of their geometric loci satisfied algebraic equations of degree 2 in x and y . Later, Isaac Newton studied polynomial equations of degree 3 and classified the corresponding loci, cubics, into 72 kinds. Thus, Descartes, Fermat, and Newton can be credited with initiating the study of plane algebraic curves, *i.e.*, loci given by polynomials of arbitrary degree, a basic topic in algebraic geometry.

The scope and generality of modern algebraic geometry are increased by adoption of certain ideas from projective geometry. For example, two (distinct) straight lines should meet in just one point. This is correct except in the case of parallel lines. This exception can be technically circumvented by introducing so-called "points at infinity" and dealing with the images of the lines in the projective plane. Plane geometric curves are represented in the projective plane by homogeneous polynomial equations (a polynomial is homogeneous if all its terms have the same degree). In the projective plane any two (distinct) straight lines, parallel or not, meet in precisely one point. Another difficulty, that of counting the intersections of tangent curves, is overcome by assigning a point of tangency the multiplicity 2.

In these developments some typical phenomena may be noted: in studying the geometry, the understanding of what geometry is changes; and new algebraic methods are devised. A curve in the projective plane over the complex numbers cannot be perceived in the way a real curve in the affine plane is, but geometric terminology, governed by logic, remains valid.

In the plane a point is given by two coordinates (x,y) , and in ordinary space by three (x,y,z) . One may call, for any positive integer n , a sequence (x_1, \dots, x_n) of numbers a point of (affine) n -space. In n -space an algebraic variety is defined as the set of points satisfying a system of polynomial equations: $F_1(x_1, \dots, x_n) = 0$, $F_2(x_1, \dots, x_n) = 0, \dots$. These objects and their generalizations are the main objects of study in algebraic geometry.

algebraic number, real number for which there exists a polynomial equation with natural numbers or their negatives as coefficients such that the given real number is a solution.

Examples of algebraic numbers are all natural numbers, all rational numbers, and some but not all irrational numbers. Numbers such as that symbolized by the Greek letter pi, π , which are not algebraic, are called transcendental numbers.

algebraic surface, in three-dimensional space, a surface the equation of which is $f(x, y, z) = 0$, with $f(x, y, z)$ a polynomial (*q.v.*) in x, y, z . The order of the surface is the degree of the polynomial equation. If the surface is of the first order, it is a plane. If the surface is of order two, it is called a quadric surface. By rotating the surface, its equation can be put in the form $Ax^2 + By^2 + Cz^2 + Dx + Ey + Fz = G$. If A, B, C are all not zero, the equation can generally be simplified to the form $ax^2 + by^2 + cz^2 = 1$. This surface is called an ellipsoid (*q.v.*) if a, b , and c are positive. If one of the coefficients is negative, the surface is a hyperboloid (*q.v.*) of one sheet; if two of the coefficients are negative, the surface is a hyperboloid of two sheets. A hyperboloid of one sheet has a saddle point (a point on a curved surface at which the curvatures in two mutually perpendicular planes are of opposite signs).

If A, B, C are possibly zero, then cylinders, cones, planes, and elliptic or hyperbolic paraboloids may be produced. Examples of the latter are $z = x^2 + y^2$ and $z = x^2 - y^2$, respectively. Through every point of a quadric pass two straight lines (possibly imaginary) lying on the surface. A cubic surface is one of order three. It has the property that 27 lines lie on it, each one meeting 10 others. In general, a surface of order four or more contains no straight lines.

Algeciras, port town, Cádiz province, in the autonomous community (region) of Andalusia, in extreme southern Spain, across the Bay of Gibraltar from Gibraltar.

The port, at the mouth of the Río de la Miel, was founded in 713 by Moors and is probably on the site of the Roman Portus Albus; its Arabic name, al-Jazīrah al-Khadrā', means Green Island, in reference to the offshore Isla Verde. The port was taken by Alfonso XI of Castile in 1344, then recaptured and destroyed in 1368 by the Moors. It was refounded in 1704 by Spanish refugees from Gibraltar and in 1760 was rebuilt by Charles III on its present rectangular plan. The Algeciras Conference (*q.v.*) was held in 1906 in the Casa Consistorial (Town Hall).

The town's main commercial activity is connected with the port, which is a stopping place for transatlantic shipping and handles many passengers, especially from the ferry services to and from Tangier and other ports in Morocco. Tourism, based on the mild winter climate, is growing. Algeciras also has ice-making and preserving plants, and fishing and fish salting are the main occupations. Local agricultural products include cereals, tobacco, hogs, and cattle. Pop. (1998 est.) 101,972.

Algeciras Conference (Jan. 16–April 7, 1906), international conference of the great European powers and the United States, held at Algeciras, Spain, to discuss France's relationship to the government of Morocco. The conference climaxed the First Moroccan Crisis (*see* Moroccan crises).

Two years earlier an Entente Cordiale, signed by Great Britain and France, had provided, among other things, for British support of French special interests in Morocco. France's attempt to implement the agreement by presenting the Moroccan sultan with a program of economic and police "reforms" brought the indignant German emperor William II to Tangier in March 1905. William challenged French intentions by affirming the sovereignty of the Sultan and demanding the retention of the "open door" for commerce.

Tension was relieved as U.S. Pres. Theodore Roosevelt was prevailed upon by the Emperor

to help bring about the 1906 conference in Algiers. Contrary to German expectations, only Austria-Hungary supported Germany's views; Italy, Russia, and, more significantly, Britain and the United States lined up behind France. On the surface, nevertheless, the convention, the Act of Algiers, signed on April 7, 1906, appeared to limit French penetration. It reaffirmed the independence of the sultan and the economic equality of the powers, and it provided that French and Spanish police officers be under a Swiss inspector general.

The real significance of the Algiers Conference is to be found in the substantial diplomatic support given France by Britain and the United States, foreshadowing their roles in World War I, to which the Moroccan Crisis was a prelude.

Alger (city, Algeria): see Algiers.

Alger OF LIÈGE, also called ALGER OF CLUNY, or ALGERUS MAGISTER (b. c. 1060, Liège, Lower Lorraine [now in Belgium]—d. c. 1131, Cluny, Burgundy [now in France]), Flemish priest famed in his day for his learning and writings.

Alger was first a deacon of the Church of Saint-Barthélemy at Liège and was appointed (c. 1100) to the cathedral church of St. Lambert. He declined many offers of posts from German bishops and retired to the Monastery of Cluny.

His *History of the Church of Liège* and many of his other works are lost. The most important of those remaining are *Liber de misericordia et justitia* ("On Mercy and Justice"), a collection of biblical and patristic extracts with a commentary—an important work for the history of church law and discipline; *De sacramentis corporis et sanguinis Dominici* ("Concerning the Sacraments of the Body and the Blood of the Lord"), a treatise on the Eucharist in opposition to the Berengarian heresy and highly commended by Peter of Cluny and Erasmus; *Libellus de libero arbitrio* ("On Free Will"), in B. Pez's *Anecdota* (vol. 4); and *De sacrificio missae* ("On the Sacrifice of the Mass"), in the *Scriptorum veterum nova collectio* ("New Collection of Ancient Writers") of Angelo Mai (vol. 9).

Alger, Horatio, also called HORATIO ALGER, JR. (b. Jan. 13, 1832, Chelsea, Mass., U.S.—d. July 18, 1899, Natick, Mass.), one of the most popular American authors in the last 30 years of the 19th century and perhaps the most socially influential American writer of his generation.

Alger was the son of a Unitarian minister, Horatio Alger, Sr., who tutored him in reading from the age of six. The young Alger showed an interest in writing, and at Harvard University he distinguished himself in the classics and graduated in 1852 with Phi Beta Kappa honours. After leaving Harvard, Alger worked as a schoolteacher and contributed to magazines. In 1857 he enrolled in the Harvard Divinity School, from which he took his degree in 1860. He then took a seven-month tour of Europe and returned to the United States shortly after the outbreak of the American Civil War. During the war he was rejected for army service.

Alger was ordained in 1864, and he accepted the pulpit of a church in Brewster, Mass., but he was forced to leave in 1866 following allegations of sexual activities with local boys. In that year he moved to New York City, and, with the publication and sensational success of *Ragged Dick; or, Street Life in New York with the Bootblacks* (serialized in 1867, published in book form in 1868), the story of a poor shoeshine boy who rises to wealth, Alger found his lifelong theme. In the more than 100 books that he would write over 30 years, Alger followed the rags-to-riches formula that he had hit upon in his first book.

The success of *Ragged Dick* led Alger to

actively support charitable institutions for the support of foundlings and runaway boys. It was in this atmosphere that Alger wrote stories of boys who rose from poverty to wealth and fame, stories that were to make him famous and contribute the "Alger hero" to the American language. In a steady succession of books that are almost alike except for the names of their characters, he preached that by honesty, cheerful perseverance, and hard work, the poor but virtuous lad would have his just reward—though the reward was almost always precipitated by a stroke of good luck. Alger's novels had enormous popular appeal at a time when great personal fortunes were being made and seemingly unbounded opportunities for advancement existed in the United States' burgeoning industrial cities. Alger's most popular books were the *Ragged Dick*, *Luck and Pluck*, and *Tattered Tom* series. His books sold over 20 million copies, even though their plots, characterizations, and dialogue were consistently and even outrageously bad.

By the mid-1890s his health was waning, and Alger settled in Natick, Mass., with his sister Olive and her husband. He died there a few years later.

BIBLIOGRAPHY. Edwin P. Hoyt, *Horatio's Boys* (1974, reissued 1983); Gary Scharnhorst and Jack Bales, *The Lost Life of Horatio Alger, Jr.* (1985).

Algeria, officially DEMOCRATIC AND POPULAR REPUBLIC OF ALGERIA, Arabic AL-JAZĀ'IR, or AL-JUMHŪRĪYAH AL-JAZĀ'IRĪYAH AD-DĪMUQRĀṬĪYAH ASH-SHĀ'BIYAH, country of Africa, located on the Mediterranean coast in the Maghrib (northwestern Africa). It is the second largest country on the continent (after The Sudan). It extends about 1,240 miles (2,000 km) from north to south and about 1,120 miles (1,800 km) at its widest from east to west. Algeria is bounded to the east by Tunisia and Libya, to the southeast by Niger, to the southwest by Mali, Mauritania, and Western Sahara, and to the northwest by Morocco and fronts the Mediterranean Sea to the north. The capital is Algiers. Area 919,595 square miles (2,381,741 square km). Pop. (2003 est.) 31,800,000.

A brief treatment of Algeria follows. For full treatment, see MACROPAEDIA: North Africa.

For current history and for statistics on society and economy, see BRITANNICA BOOK OF THE YEAR.

The land. Algeria's large Saharan region in the south, which is almost entirely uninhabited desert, occupies slightly more than 85 percent of its total area; a smaller northern region along the Mediterranean coast—the Tell—consists of interspersed plains and mountain ranges of the Atlas system. This system includes, from north to south, folded intermittent coastal massifs and the plains that separate and extend south of them; the Tell Atlas (Atlas Tellien), a section of the Maghrib's Atlas Mountains, which extend into Morocco to the west and into Tunisia to the

east; the semiarid High Plateau (Hauts Plateaux); and the Saharan Atlas (Atlas Saharien), which separates the Maghrib from the arid Sahara to the south. This desert is generally more homogeneous in appearance, with its vast areas of stony pavement, known as regs, and its great expanses of free sand dunes called ergs, but it also provides Algeria with its most striking mountains—the Ahaggar (Hoggar) in the southeast—and its highest peak—Mount Tahat at 9,573 feet (2,918 m). The northern Tell ranges lie along a tectonic-plate boundary and periodically experience severe seismic activity. In 1717 a large earthquake completely destroyed the town of Onan, and in 1790 Algiers lost about 20,000 people to major earthquakes. In 1954 and 1980 earthquakes killed some 5,200 people at Chlef (el-Asnam), and an earthquake centred about 40 miles (60 km) east of Algiers killed some 2,200 people in 2003.

Algeria's major rivers are located in the north where precipitation is greatest. Scattered oases tapping deep underground aquifers or watered by artesian springs are the only reliable sources of water in the Sahara region. Algeria's rivers tend to be seasonal or intermittent because of the uneven seasonal distribution of precipitation, and only the development of reservoirs (primarily in the vicinity of Algiers) allows year-round irrigation. The basins of the Chelif and Hamiz rivers provide about one-third of the country's irrigation needs.

Precipitation (averaging generally less than 32 inches [800 mm] and often less than 16 inches [400 mm] per year) in the north is meagre, and the amount of rainfall may vary drastically from year to year. On the southern border of the Saharan Atlas, where rainfall is less than 4 inches (100 mm) per year and perennial drought exists, the Sahara proper begins. Algeria's winters (December to March) are rainy in the north, but near-drought conditions prevail there for the rest of the year.

The annual range in average monthly temperatures in the coastal area is comparatively low, with typical differences of only about 20° F (11° C) between the warmest and coolest months. Algiers, for example, has average afternoon temperatures in July of 83° F (28° C), which drop to about 70° F (21° C) at night, while in January daily temperatures range between 59° and 49° F (15° and 9° C). Both daily and annual temperature ranges become greater moving inland and reach an extreme in the desert.

Forests of oak, conifers, and juniper are limited and located almost exclusively in the northeast and in the Tell Atlas. The steppelike climate of the High Plateau, a transition zone, supports only grasses and some shrubs. Endangered animals include the leopard, the cheetah, and a number of species of gazelle.

Natural-gas fields, in north-central and northeastern Algeria, are among the world's largest known reserves. Algeria has one of the largest petroleum resource bases in Africa, following Libya and Nigeria. As Africa's only producer of mercury, Algeria provides about one-tenth of the world's supply. Major iron-ore reserves include those worked at Ouenza and undeveloped deposits in the western desert at Gara Djebilet.

The people. Some four-fifths of Algeria's people are Arabs; Berbers are the main minority group. The major languages are Arabic (the official language) and Berber, with a few native French speakers. Berber ethnic groups found in Algeria include the Kabyles, the Shawias (Chaouïas), and the M'zabites. Tuaregs, another Berber subgroup, are nomadic herders who live mainly on small oases, such as Adrar in southwestern Algeria, or in the Ahaggar Mountains in the southeast. The remaining population consists of relatively small

Algeria

numbers of French, Spanish, and Italian Europeans. Islām is the official religion.

Algeria's population has a high annual rate of growth, and one that is above average for North Africa. Birth rates have declined steadily since the 1950s, but death rates have declined even more, largely offsetting the effects of the lower birth rates. More than two-fifths of the total population is younger than 15 years of age, and about half live in urban areas. Emigration to Europe, once an alternative for Algeria's unemployed, declined from the mid-1970s after France restricted further immigration. Life expectancy is higher than the average for North Africa at 67 years for men and 69 years for women.

The economy. Algeria has a centrally planned developing economy that is partly private in structure and is based primarily on the production and export of petroleum and natural gas. The gross national product (GNP) is growing somewhat less rapidly than the population; nevertheless, the GNP per capita is one of the highest in Africa.

Only about 3 percent of Algeria's land is arable. Most of that is cultivated, but only a small percentage can be irrigated. Crops grown include wheat, barley, market vegetables, potatoes, fruit (such as oranges), dates, olives, grapes, and smaller quantities of peas, beans, lentils, tobacco, and sugar beets. Pastures consist mostly of arid rangeland, and the livestock raised on them includes sheep, goats, and cattle, as well as asses, mules, camels, and horses. Algeria's agricultural sector produces only about one-fourth of national food requirements, and the rest must be imported.

Forests, badly devastated during Algeria's war of independence, have been partly restored under reforestation programs. Algeria has large stands of cork oak and ranks among the top cork producers in the world. Despite the country's long Mediterranean shoreline, its fisheries remain underdeveloped.

Besides petroleum and natural gas, important minerals produced include high-grade iron ore; sand, gravel, and crushed stone; and phosphate rock. Algeria cut back its oil production in the 1980s to extend the life of its reserves. Nearly all of the country's electricity is produced by thermal plants, with the small remainder by hydroelectric plants.

Manufacturing is dominated by the hydrocarbon sector and includes liquefied natural gas (LNG) and refined petroleum products. Other important manufactures are crude steel and pig iron, liquefied petroleum gas (LPG), naphtha, plastics, fertilizers, bicycles, tractors, and motors. Light manufacturing includes ceramics, paints, polyester textiles, electrical goods, shoes, flour, edible-vegetable oils, wine, and cigarettes.

Since independence in 1962 Algeria has gradually nationalized its hydrocarbon, mining, heavy-industry, transportation, finance, and foreign-trade sectors. Light consumer-oriented industries and some housing construction remain in private control, as do retail trade, the ownership of small property holdings, and part of the country's agriculture.

The largest portion of the economically active population is employed in agriculture (as much as one-fifth of the total), followed by services, manufacturing, construction, and trade and finance. The overall trade-union organization is the General Union of Algerian Workers, organized in 1956 and closely linked to the government. Farmers are represented by the National Union of Algerian Peasants.

Budgetary revenue originates from hydrocarbon revenues (about half of the total) as well as from corporate and other taxes. Algerian banking was nationalized between 1967 and 1972.

Algeria's railway network is concentrated in

the north. About two-thirds of the road network is paved. Three trans-Saharan roads have been built; the most extensive one is a paved route extending from el-Golēa to Tamanghasset and then south with one branch to Niger (completed in 1985) and another to Mali. Algiers is the country's main port; other major ports are at Arzew, Bejaïa, and Oran. There are five international airports and a number of smaller airports and airstrips. Algeria's pipeline network links the Saharan oil and natural-gas fields to Mediterranean ports.

Petroleum and natural gas dominate Algeria's exports, which also include fertilizers, wine, citrus fruit, and pig iron. The largest importers of Algerian products are Italy, France, the United States, and The Netherlands. Imports include food, nonelectrical machinery, iron and steel, and consumer products. The most important import sources are France, Italy, and the United States.

Government and social conditions. From independence in 1962 Algeria was governed by the National Liberation Front (Front de Libération Nationale; FLN), which was the sole legal political party. The FLN governed through an elected president, a prime minister appointed by him, and an elected National People's Assembly. In 1989 a new constitution created a multiparty political system, and in the early stages of the country's first free national elections in 1991, the fundamentalist Islāmīc Salvation Front (Front Islamique du Salut; FIS) won the largest share of the vote. The armed forces then took power to prevent the fundamentalists from gaining control of the National People's Assembly.

Algeria is still plagued by such serious diseases as tuberculosis, trachoma, measles, dysentery, venereal infections, and typhoid. Medical facilities are inadequate in rural areas, prompting the government to sponsor disease-prevention measures, health education, and expanded health programs for rural areas. High population growth and migration from rural to urban areas have created a severe housing shortage in the cities.

The literacy rate in Algeria is little more than 50 percent, and much of that is in French, not Arabic. Education is officially compulsory for school-age children for a period of nine years, and about 90 percent of all school-age children receive some education. Only about half of all secondary-age children attend secondary school, however. Four-fifths of the population aged 25 and over never have had any formal schooling. The major centre of higher education is the University of Algiers (founded in 1879).

The government controls most of the printed and electronic news media in Algeria. The most widely circulated newspaper is *El-Moudjahid*, the official organ of the state.

Cultural life. Since independence from France (1962), the government has endeavoured to strengthen the traditional Arabic cultural heritage that was largely repressed during the years of French rule. One of the major traditional and modern art forms is literature. The literary art includes that written in the French language by individuals of French descent born in Algeria, such as Albert Camus, Emmanuel Robles, and René-Jean Clot; literature by native Algerians also written in French, but of Algerian expression, by writers who present a view of the contemporary scene; and poetry and plays written in Arabic or Berber dialects. Rugs, jewelry, and woodwork are also notable, if more traditional, major art forms. The religion of Islām provides a cultural link to the past; the citizenry still celebrates Islāmīc festivals such as Mouloud, which commemorates the birth of the prophet Muḥammad. The country has many ethnographic and archaeological museums, a National School of Fine Arts, and fine examples of early architecture in its many old and beautiful domed mosques.

History. Archaeological excavations in northern Algeria have revealed the presence of *Homo erectus* there some 500,000 to 700,000 years ago. Phoenician traders settled on the Mediterranean coast early in the 1st millennium BC. Carthage, in present-day Tunisia, became Phoenicia's most important city, and later it was the centre of an empire of its own. Carthage fell to the Romans in 146 BC; by AD 40 Roman control was firmly established at least along the coast, and Algeria became part of what the Romans called Mauretania Caesariensis. The hinterlands, however, remained outside Roman control. The fall of Rome in the 5th century led to invasion by the Vandals and, after them, the Byzantines. During this period Christianity grew in importance, and Latin was in general use throughout North Africa. The Islāmīc invasion began in the 7th century; by 711 all of North Africa was under control of the Umayyad caliphate, and the indigenous Berbers were becoming Islāmīcized.

In 740, under influence of the Khārijite heresy, the North Africans wrested control from the Umayyads, and several Islāmīc Berber empires followed, the most famous being the Almoravid (c. 1054–1130), which extended its domain to Spain, and the Almohad (c. 1130–1269). They are remembered as nurturing the golden age of North African Islāmīc civilization. The decline of the Almohads was coupled with an influx of Bedouin immigrants who transformed the basically sedentary population into a nomadic one.

Early 16th-century incursions into North Africa by Spain led the Africans to appeal to the Ottomans, who, by 1536, established effective control of the region. The Barbary pirates menaced Mediterranean trade for centuries and gave the French a pretext to enter Algeria in 1830. By 1847 the French had subdued most Algerian resistance, though fighting occurred as late as 1884. Algerian movements for national independence from France resulted in the uprisings of 1954–55, inaugurating the bitter Algerian War of Independence, in which a French army of 500,000 sought to suppress the National Liberation Front (FLN) and pacify the country. President Charles de Gaulle of France promoted peace negotiations, culminating in 1962 in a plebiscite on independence, which carried. Most of the large French community departed as the FLN took over the government and led Algeria to independence on July 3, 1962. Under Colonel Houari Boumedienne (ruled 1965–78) and Colonel Chadli Bendjedid (ruled 1979–92), Algeria became a socialist, centrally directed economy with a state-run oil and gas industry. The FLN's long hold on power spawned increasing corruption and mismanagement, however, and serious antigovernment rioting in 1988 prompted the FLN to adopt a new constitution in 1989 allowing multiparty elections. The supreme role of the FLN was quickly challenged by other parties, most notably those espousing Islāmīc fundamentalism, and after the FIS appeared ready to win the largest share of the vote for seats in the National People's Assembly in 1991, a military group seized power. Islāmīc fundamentalist groups then launched a campaign of terrorism and retaliatory violence against the government. By 1995 Algeria had plunged into a state of virtual civil war as the government's security forces tried unsuccessfully to crush the armed Islāmīc opposition.

Algerian Reformist Ulama, Association of, also called ASSOCIATION OF ALGERIAN MUSLIM ULAMA, French ASSOCIATION DES ULÉMA REFORMISTES ALGÉRIENS, or ASSOCIATION DES ULÉMA MUSULMANS ALGÉRIENS, Arabic JAM'ĪYAH AL-'ULAMĀ' AL-JAZA'RĪYAH, a body of Muslim religious scholars (ulama) who, under French rule, advocated the restoration of an Algerian nation rooted in Islāmīc and Arabic traditions.

The association, founded in 1931 and formally organized on May 5, 1935, by Sheikh Abd al-Hamid ben Badis, was heavily influenced by the views of the great Muslim reformer Muḥammad 'Abduh (1849–1905). It adopted his belief that Islām was essentially a flexible faith, capable of adapting to the modern world if freed of its non-Islāmic and vulgar accretions. The Algerian Ulama thus conducted widespread campaigns against the superstition and maraboutism common among the Muslim masses. They also implemented 'Abduh's belief in the efficacy of modern education by attempting to reform the antiquated educational system that had perpetuated a medieval mentality in the country. More than 200 schools were opened, the largest at Constantine with about 300 students, and the possibility of a Muslim university was introduced but never realized. The Algerian Ulama stressed the importance of studying Arabic, the language of Algerian Muslims, and fought for its obligatory instruction in Algerian elementary and secondary schools. In effect, the Association of Algerian Ulama wished to give the Algerian Muslim an identity and tradition rooted in the Islāmic community (*ummah*) and distinct from his French colonizer. Sheikh ben Badis condemned the adoption of European culture by Algerian Muslims, issuing a formal *fatwā* (legal opinion) against it in 1938.

The association met with opposition from two sources. Gallicized Algerian Muslims, known as *évolués*, Arabs by tradition and Frenchmen by education, insisted that Islām and France were not incompatible. They rejected the idea of an Algerian nation and stated that Algeria had for generations been identified in terms of its economic and cultural relations with France.

Traditional Muslim circles also rejected the Association of Algerian Ulama. The leaders of the Muslim Šūfī (mystic) brotherhoods and the marabouts were directly threatened by the purist drive of the Ulama, while the Islāmic functionaries—imams (prayer leaders in the mosques), qadis (religious judges), and muftis (religious lawyers)—were affected by their educational reforms and anti-French sentiment.

The popular response to the programs of the association was nonetheless considerable. To counteract the growing influence of the Ulama, the French government issued the *circulaire Michel*, which forbade members of the association from preaching in the mosques. The association, however, did not curtail its activities, even with the arrest of ben Badis in 1938. Sheikh Talib al-Bashir Brahimi succeeded ben Badis on his death in 1940. During the Algerian war of independence against France (1954–62), the association aligned with the National Liberation Front (1956), and Tawfiq al-Madani, secretary-general of the Algerian Ulama, sat in the provisional government of the Algerian Republic after independence (1962).

Algerus MAGISTER: see Alger of Liège.

Alghero, town and episcopal see, Sassari *provincia*, northwestern Sardinia, Italy, southwest of Sassari city. It was founded in 1102 by the Doria family of Genoa and became a Catalan colony under Peter IV of Aragon in 1354. Emperor Charles V took up residence there in 1541. It is the only Italian town where the Catalan language is still spoken and where traces of the Aragonese architectural style can be seen (in the 16th-century cathedral). The 14th-century Church of San Francesco is another notable monument. An old fishing port, Alghero has modern beach-resort facilities. Coral fishing in season, fruit canning, sawmilling, and olive-oil production are the principal industries. Pop. (2001) 38,404.

Algiers, French ALGER, Arabic AL-JAZĀ'IR, capital and chief seaport of Algeria. It is the

political, economic, and cultural centre of the nation.

The city of Algiers is built on the slopes of the Sahel Hills, which parallel the coast, and it extends for 10 miles (16 km) along the Bay of Algiers. The city faces east and north and forms a large amphitheatre of dazzling white buildings that dominate the harbour and the bay. The city takes its name (Arabic: "The Island") from several small islands that formerly existed in the bay, all but one of which have been connected to the shore or obliterated by harbour works.

Algiers was founded by the Phoenicians as one of their numerous North African colonies. It was known to the Carthaginians and the Romans as Icosium. The town was destroyed by the Vandals in the 5th century AD. It was revived under a Berber dynasty in the 10th century as a centre of commerce in the Mediterranean. In the early 16th century many of the Moors expelled from Spain sought asylum in Algiers. Some of them began making piratical attacks on Spanish seaborne commerce, and in response Spain in 1514 fortified the offshore island of Peñon in the Bay of Algiers. The emir of Algiers appealed to two Turkish corsairs to expel the Spaniards from the Peñon, and one of the corsairs, Barbarossa (Khayr ad-Dīn), seized Algiers in 1529, expelled the Spaniards, and placed Algiers under the authority of the Ottoman sultan. Barbarossa's efforts turned Algiers into the major base of the Barbary pirates for the next 300 years. The European powers made repeated vain attempts to quell the pirates, including naval expeditions by the Holy Roman emperor Charles V in 1541 and by the British, Dutch, and Americans in the early 19th century. Piracy based in Algiers continued, though much-weakened, until the French captured the city in 1830. The French made Algiers a military and administrative headquarters for their colonial empire in North and West Africa.

During World War II Algiers became the headquarters of Allied forces in North Africa and for a time the provisional capital of France. In the 1950s, when the Algerian uprising against France began, the capital city was a focal point in the struggle. After 1962, when Algeria became independent, many far-reaching changes were made to the city as the new government set out to create a modern socialist society out of a backward colonial one. A large portion of the city's European

Minarets of the mosque of Ketchaoua overlooking the Place des Martyrs, Algiers, Alg.
Shostal Assoc

population left in the decades following Algerian independence.

The city suffered several natural disasters in the early 21st century. In 2001 a flood killed hundreds, and in 2003 a powerful earthquake centred near the city killed thousands. The old Turkish, or Muslim, section of Algiers is built on the upper slopes of the hills and has preserved much of its architectural character of high, blank-walled houses and narrow, winding streets. The Muslim section is dominated by the fortress of the Kasbah (Qaşbah), which was the residence of the last two Turkish deys, or governors, of Algiers. A prominent building in the Muslim section is the Ketchaoua Mosque, which prior to 1962 was the Cathedral of St. Philip (constructed 1845–60). The French section of Algiers grew along the lower slopes of the hills, closer to the harbour. This section has numerous public squares and wide boulevards. Situated in the modern city centre are the University of Algiers (1879) and numerous foreign embassies and a few skyscrapers. Other sites include the modern building of the National Library; the old palace of the archbishop, formerly the palace of the dey; and the Winter Palace, which was formerly the palace of the French governor-general. Algiers has continued to grow to the south, with new suburbs being created to house the overflow from the city centre.

Algiers is chiefly a port for the import of raw materials, industrial goods, and general supplies. The main exports are wine, early vegetables and oranges, iron ore, and phosphates. The airport, Dar el-Beida, lies east of the city. Pop. (1998) 1,519,570.

Consult the INDEX first

Algirdas, Polish OLGIERD (b. c. 1296—d. 1377), grand duke of Lithuania from 1345 to 1377, who made Lithuania one of the largest European states of his day. His son Jogaila became Władysław II Jagiełło, king of united Poland and Lithuania.

Algirdas was one of the sons of the country's ruler, Gediminas, and he began his long political career when he married, at his father's request, the daughter of the prince of Vitebsk and succeeded to the prince's lands. Together with his father he fought against the Teutonic Knights and attempted to subjugate the Russian territories of Novgorod and Pskov, which had sought Lithuanian protection both from the knights and from the Golden Horde (the Tatar overlords of Russia since the middle of the 13th century). From 1341 to 1345 he was prince of Krevo and Vitebsk and a vassal of his younger brother, Grand Duke Jaunutis, whom he removed in collusion with another brother, Kęstutis, with whose consent he became grand duke.

Defense of Lithuanian Ponemune and Podvine against the knights and their allies, invasion of the Russian and Ukrainian lands subject to the Horde, and the desire to achieve Lithuanian hegemony in the province of Volhynia were the goals of Algirdas' foreign policy. In the pursuit of these aims he relied on dynastic support and especially on his coruler Kęstutis. The brothers shared both their losses and their many acquisitions of fortified posts in Russia. They were supported by the princes and boyars who sat in the grand-ducal council and who, along with their feudal-dependent peasants, took the field under them.

But though he was the leader of the Lithuanian-Slavic armies against the Teutonic Knights, Algirdas was a stranger to the lower social orders. When, during the anti-German "Uprising of the Night of Yury" in Livonia (1345), one of its leaders, a peasant, told him that he had been chosen king by the rebels

and that if Algirdas followed his advice the Germans would be driven out, Algirdas had him decapitated. To the feudal prince, a peasant as king seemed a more terrible threat than the German usurpers.

Although pagan to the core, Algirdas allowed his Orthodox subjects of Vilnius to build a church where formerly the gallows had stood. For political reasons he appointed many Orthodox vice-regents in the Slavic territories of Lithuania, consistently married Orthodox princesses himself, and prevailed on the patriarch of Constantinople to found a Lithuanian Orthodox metropolitan see in the city of Kiev.

Algirdas saw far beyond the boundaries of his country. When the Polish king Casimir III the Great, Pope Clement VI, and the Holy Roman emperor Charles IV proposed to him that he accept Catholicism, he replied (1358) that he was ready to do so if they returned to him the lands between the Pregolya and Daugava rivers, liquidated the Teutonic Knights, and left him the

empty lands between the Tatars and the Russians for their protection from the Tatars, leaving the Knights no rights whatever over the Russians but instead granting all Rus [Russia] to the Lithuanians.

But Algirdas' goals were not destined to be realized.

Early in his reign the Teutonic Knights and their allies conducted annual raids from their bases in Prussia and Livonia, ruining Lithuanian lands and subjugating White Russia as far south as Grodno. Aided by their supporters to the east and south, Algirdas and Kęstutis repelled these attacks. Yet, despite the expenditure of so much energy, Algirdas left the resolution of this historic struggle with the Teutonic Knights to his heirs.

The rivalry with Poland over Volhynia was intensified when, in 1349, Casimir tricked Algirdas' brother Lubart out of one of the principal Volhynian cities. By the treaty of 1352 Lithuania took possession of Volhynia, but in 1366, preoccupied with his struggle with the Teutonic Knights, Algirdas had to yield most of Volhynia once again to his ally Casimir. After Casimir's death in 1370, however, he managed to recover part of the province by a treaty (1377) with King Louis of Hungary-Poland.

Algirdas' relations with Russia were characterized by his unsuccessful attempts to claim Pskov and Novgorod. Having met with Muscovite resistance, he concluded peace with Grand Duke Simeon of Moscow (1349). But with the decline of the Golden Horde after 1357, he extended his influence eastward approximately as far as Mstislavl' and Bryansk. In 1362-63 he campaigned in the territories of the Tatars, defeating three of their governors in the battle at the River Siniye Vody. He secured the principality of Kiev, which he gave to his son Vladimir, and freed Little Podolia from the power of the Golden Horde.

In 1349 Algirdas married Yuliana, daughter of the prince of Tver. Together with Tver and Smolensk he undertook three campaigns against Moscow (1368, 1370, 1372). They were, however, unsuccessful because of an increase in Moscow's prestige among the other Slavic lands.

Algirdas died in the middle of a war with the Knights. He was apparently cremated, along with 18 of his warhorses and other effects. He left his lands to his 12 sons. According to a contemporary chronicle, he

drank not beer nor mead, nor wine nor fermented kvass. He was temperate and thus found wisdom. And by his cunning he conquered many lands and countries, subjugated many towns and principalities, and achieved great power.

(V.T.P.)

Algol, also called **BETA PERSEI**, prototype of a class of variable stars called eclipsing binaries, the second brightest star in the northern constellation Perseus. Its apparent visual magnitude changes periodically over the range of (approximately) 2.2 to 3.5; even at its dimmest it remains readily visible to the unaided eye. The name probably derives from an Arabic phrase meaning "demon," or "mischief-maker," and the Arabs may have been aware of the star's variability even before the invention of the telescope.

The first European astronomer to note the light variation was the Italian Geminiano Montanari in 1670; the English astronomer John Goodricke measured the cycle (69 hours) in 1782 and suggested partial eclipses of the star by another body as a cause, a hypothesis proved correct in 1889. The comparatively long duration of the eclipse shows that the dimensions of the two stars are not negligible in comparison with the distance between them. Small fluctuations in the period of the light variation can be explained by assuming that the system contains two other stars, which take no part in the eclipses. The presence of one companion with a period of 1.87 years has been confirmed by spectroscopic observations.

algology, also called **PHYCOLOGY**, the study of algae, a large heterogeneous group of chiefly aquatic plants ranging in size from microscopic forms to species as large as shrubs or small trees. The discipline is of immediate interest to humans owing to algae's importance in ecology. Certain algae, especially planktonic (*i.e.*, floating or drifting) forms, constitute a vital segment of food chains. In coastal regions many large species of algae are direct food sources for humans. In industry algae are a source of commercially valuable substances such as iodine, agar, carrageenin, alginic acid, and potash. Other algae are used in insulating materials, bricks, scouring powder, and filters. Certain species are used as digestive agents in sewage-oxidation ponds. Some forms of algae are harmful because of their tendency to suffocate other forms of aquatic life in waters used for fishing and recreation.

Algonquian languages, also spelled **ALGONKIAN**, North American Indian language family whose member languages are or were spoken in Canada, New England, the Atlantic coastal region southward to North Carolina, and the Great Lakes region and surrounding areas westward to the Rocky Mountains. Among the numerous Algonquian languages are Cree, Ojibwa, Blackfoot, Cheyenne, Micmac, Arapaho, and Fox-Sauk-Kickapoo. The term Algonquin (often spelled this way to differentiate it from the family) refers to a dialect of Ojibwa. Algonquian languages have been classified by some scholars as belonging to a larger language group, the Macro-Algonquian phylum. *See also* Macro-Algonquian languages.

Algonquin, any of a number of scattered Algonquian-speaking bands and tribes living in dense forest regions on either side of the upper Ottawa River in Canada. They drew cultural traits from tribes flanking them on east and west, the Montagnais and Naskapi and the Ojibwa. Primarily hunters, engaging in only marginal corn (maize) cultivation, they were always few in number and were decimated by Iroquois raids and European diseases. About 2,000 survived into the late 20th century, however, making their living mainly as truck gardeners, hunters' guides, and trappers.

Algonquin, Lake, large glacial lake that once existed in North America and covered most of the area now occupied by the Great Lakes of Superior, Michigan, and Huron. It was present in the Pleistocene Epoch (1,600,000 to 10,000 years ago), a geologic glacial period when the ice field (called the Laurentide Ice Sheet) was

retreating northward from the Great Lakes region. The body of water, perhaps 100,000 square miles (250,000 square km) in area and with depths of up to 1,500 feet (460 m), at various stages drained through channels that included the Trent Valley and the Mattawa, Ottawa, St. Clair, and Mississippi rivers. Remnants of the lake include Lakes Superior, Michigan, Huron, Nipigon, Simcoe, and Nipissing.

Algonquin Provincial Park, wilderness area, southeastern Ontario, Canada. It lies about 140 miles (225 km) northeast of Toronto and covers an area of 2,955 square miles (7,653 square km). Established in 1893, the park, once a lumbering area, is a hilly wildlife refuge for bears, beaver, deer, moose, and smaller game. It straddles the drainage divide between the Ottawa River and Georgian Bay, and its numerous lakes and streams offer canoeing and fishing for bass, lake trout, pickerel, and muskellunge.

Algonquin Round Table, also called **THE ROUND TABLE**, informal group of American literary men and women who met daily for lunch on weekdays at a large round table in the Algonquin Hotel in New York City during the 1920s and '30s. The Algonquin Round Table began meeting in 1919, and within a few years its participants included many of the best-known writers, journalists, and artists in New York City. Among them were Dorothy Parker, Alexander Woollcott, Heywood Brown, Robert Benchley, Robert Sherwood, George S. Kaufman, Franklin P. Adams, Marc Connelly, Harold Ross, Harpo Marx, and Russell Crouse. The Round Table became celebrated in the 1920s for its members' lively, witty conversation and urbane sophistication. Its members gradually went their separate ways, however, and the last meeting of the Round Table took place in 1943.

algorithm, systematic mathematical procedure that produces—in a finite number of steps—the answer to a question or the solution of a problem. The question or problem, in turn, must belong to a class that has an infinite number of members, such as "Is the integer *a* prime?" or "What is the greatest common divisor of the integers *a* and *b*?" The first of these questions belongs to a class called decidable; an algorithm that produces the answer (yes or no) is called a decision procedure. The second question belongs to a class called computable; an algorithm that leads to the answer (a specific number) is called a computation procedure. For finite classes of questions, trivial algorithms always exist (at least in principle); they consist of tables of values of the answers.

Algorithms exist for many infinite classes of questions; Euclid's *Elements*, published about 300 BC, contained one for finding the greatest common divisor of two integers. Every elementary school student is drilled in long division, which is an algorithm for the question "Upon dividing an integer *a* by another integer *b*, what are the quotient and the remainder?" Use of this computational procedure leads to the answer to the decidable question "Does *b* divide *a*?" (the answer is yes if the remainder is zero). Repeated application of these algorithms eventually produces the answer to the decidable question "Is *a* prime?" (the answer is no if *a* is divisible by any smaller integer besides 1).

For other infinite classes of questions, no algorithms are known. A celebrated question of this kind has occupied mathematicians since about 1637, when Pierre de Fermat claimed to have found a proof that no set of integers *n*, *x*, *y*, *z* satisfies the equation $x^n + y^n = z^n$ for any *n* greater than 2. Fermat did not substantiate his claim, and no one since has been able to, but no refutation has been forthcoming either, although a single instance would suffice. Such

an instance would also establish an algorithm, because some finite set of calculations would lead to the integers in question, no matter how large they were.

Algren, Nelson, original name NELSON AHLGREN ABRAHAM (b. March 28, 1909, Detroit—d. May 9, 1981, Sag Harbor, N.Y.), writer whose novels of the poor are lifted from routine naturalism by his vision of their pride, humour, and unquenchable yearnings. He also catches with poetic skill the mood of the city's underside: its juke-box pounding, stench, and neon glare.

The son of a machinist, he grew up in Chicago, where his parents moved when he was three. He worked his way through the University of Illinois, graduating in journalism in the depth of the Depression. He went on the road as a door-to-door salesman and migratory worker in the South and Southwest, then returned to Chicago, where he was employed briefly by a WPA (Works Progress Administration) writers' project and a venereal-disease control unit of the Board of Health. In this period, too, he edited with the proletarian novelist Jack Conroy the *Anvil*, a magazine dedicated to the publication of experimental and leftist writing.

Somebody in Boots (1935), his first novel, relates the driftings during the Depression of a young poor-white Texan who ends up among the down-and-outs of Chicago. *Never Come Morning* (1942) tells of a Polish petty criminal who dreams of escaping from his squalid Northwest Side Chicago environment by becoming a prizefighter. Before the appearance of Algren's next book—the short-story collection *The Neon Wilderness* (1947), which contains some of his best writing—he served as a U.S. Army medical corpsman during World War II.

Algren's first popular success was *The Man with the Golden Arm* (1949; filmed 1956), which won the National Book Award. Its hero is Frankie Machine, whose golden arm as a poker dealer is threatened by shakiness connected with his dope addiction. In *A Walk on the Wild Side* (1956; filmed 1962) Algren returned to the 1930s in a picaresque novel of New Orleans bohemian life.

His nonfiction includes the prose poem *Chicago, City on the Make* (1951) and sketches collected as *Who Lost an American?* (1963) and *Notes from a Sea Diary: Hemingway All the Way* (1965).

Alhambra, palace and fortress of the Moorish monarchs of Granada, in the Andalusian region of Spain. The name Alhambra, signifying in Arabic "the red," is probably derived from the colour of the sun-dried *tapia*, or bricks made of fine gravel and clay, of which the outer walls are built.

Constructed on a plateau below which clusters the city of Granada, the palace was built chiefly between 1238 and 1358, in the reigns of Ibn al-Ahmar, founder of the Nasrid dynasty, and his successors. The splendid decorations

of the interior are ascribed to Yūsuf I (died 1354). After the expulsion of the Moors in 1492, much of the interior was effaced and the furniture was ruined, or removed. Charles V, who ruled in Spain 1516–56, rebuilt portions in the Renaissance style and destroyed part of the Alhambra to build an Italianate palace designed by Pedro de Machuca in 1526. In 1812 some of the towers were blown up by the French during the Napoleonic invasion; and in 1821 an earthquake caused further damage to the structure. Restoration of the building was undertaken in 1828 and has continued to the present.

The Moorish portion of the Alhambra includes the Alcazaba, or citadel, which is the oldest part—only its massive outer walls, towers, and ramparts are left. Beyond the Alcazaba is the Alhambra palace, and beyond that the Alhambra Alta (Upper Alhambra), which was originally tenanted by officials and courtiers and was part of a royal city, a seat of government.

The principal courts of the palace are the Patio de los Arrayanes (Court of the Myrtles) and the Patio de los Leones (Court of the Lions), so named because in the centre is the Fountain of the Lions, an alabaster basin supported by the figures of 12 white marble lions, emblems of strength and courage. The most important rooms of the Alhambra are the Sala de los Embajadores (Hall of the Ambassadors), a spatially grand reception room; the Sala de los Abencerrages (the name of this hall was derived from a legend in which Boabdil, the last king of Granada, having invited the Abencerrage chiefs to a banquet in this room, massacred them there); and the Sala de las Dos Hermanas (Hall of the Two Sisters), with its outstanding example of stalactite work (*q.v.*).

Of the outlying buildings, the most important is the Generalife (from the Moorish *Jannat al-'Arif*, or Garden of the Builder). This villa probably dates from the end of the 13th century.

Alhazen, Arabic ABŪ 'ALĪ AL-ḤASAN IBN AL-HAYTHAM (b. c. 965, Basra, Iraq—d. 1039, Cairo), mathematician and physicist who made the first significant contributions to optical theory since the time of Ptolemy (flourished 2nd century). In his treatise on optics, translated into Latin in 1270 as *Opticae thesaurus Alhazeni libri vii*, Alhazen published theories on refraction, reflection, binocular vision, focussing with lenses, the rainbow, parabolic and spherical mirrors, spherical aberration, atmospheric refraction, and the apparent increase in size of planetary bodies near the Earth's horizon. He was first to give an accurate account of vision, correctly stating that light comes from the object seen to the eye.

Alhucemas, also called AL-HOCEIMA, or AL-KHUZAMA, Spanish *plaza* (enclave) on the Mediterranean coast of Morocco, comprising a bay, three islets, and a small port. The bay, a semicircular inlet (9 mi wide and 5 mi long

[14 km wide and 8 km long]), is protected by Cap Nuevo; its sandy bottom is an extension of the Río Nekor alluvial plain. The islets, administered by Spain since 1673, are uninhabited, although Peñón de Alhucemas was garrisoned until 1961. The Moroccan port of al-Hoceima (Spanish Villa Sanjurjo), on the mainland opposite, is mainly a fishing port and its fine beaches provide the basis for a bathing resort.

Alhucemas (Morocco): see Hoceima, al-

'Alī, in full 'ALĪ IBN ABĪ ṬĀLIB (b. c. 600, Mecca—d. January 661, Kūfah, Iraq), son-in-law of Muhammad, the prophet of Islām, and fourth caliph (successor to Muḥammad), reigning from 656 to 661. The question of his right to the caliphate resulted in the only major split in Islām (into Sunnah and Shi'ah branches). He is revered by the Shi'ah as the only true successor to the Prophet.

'Alī was the son of Abū Ṭālib, chief of a local clan. When his father became impoverished, 'Alī was adopted by Muḥammad, then still a businessman in Mecca, who himself had been cared for by 'Alī's father as a child. When Muḥammad felt God's call to become his prophet, 'Alī, though only 10 years old, became one of the first converts to Islām and remained a lifelong devoted follower of Muḥammad. According to legend 'Alī risked his life by sleeping in the Prophet's bed to impersonate him the night that Muḥammad fled in 622 from Mecca to Medina from enemies who were plotting to assassinate him. In addition, 'Alī is said to have carried out Muḥammad's request to restore all the properties that had been entrusted to him as a merchant to their owners in Mecca. Only then did 'Alī himself leave for Medina. There he married Muḥammad's daughter Fāṭimah, who bore him two sons, Ḥasan and Husayn.

'Alī is said to have displayed rare courage in battle during the military expeditions Muḥammad conducted to consolidate Islām and always obtained a lion's share of the booty. 'Alī was also one of Muḥammad's scribes and was chosen to lead several important missions. When the hostile inhabitants of Mecca finally accepted Islām without battle, it was 'Alī who smashed the pagan idols in the Ka'bah (holy shrine).

Muḥammad died on June 8, 632. Some say he had unequivocally nominated 'Alī as his successor while he was returning from his "farewell pilgrimage" to Mecca. Others reject this claim, maintaining that Muḥammad died without naming a successor. 'Alī, while attending the last rites of the Prophet, was confronted by the fact that Abū Bakr, Muḥammad's closest friend and father of 'A'ishah, one of the Prophet's wives, had been chosen caliph. 'Alī did not submit to Abū Bakr's authority for some time, but neither did he actively assert his own rights, possibly because he did not want to throw the Muslim community into bloody tribal strife. He retired into a quiet life in which religious works became his chief occupation. The first chronologically arranged version of the Qur'ān is attributed to him, and his excellent knowledge of the Qur'ān and Ḥadīth (the sayings and deeds of Muḥammad) aided the caliphs in various legal problems.

Following the murder of 'Uthmān, the third caliph, 'Alī was invited by the Muslims of Medina to accept the caliphate; reluctant, he agreed only after long hesitation. His brief reign was beset by difficulties due mostly to the corrupt state of affairs he inherited. Acutely aware of the neglect of the Qur'ān and the traditions of Muḥammad that his predecessors had allowed to develop, he based his rule on the Islāmic ideals of social justice and equality. His policy was a blow to the interests of the Quraysh aristocracy of Mecca

The Alhambra, Granada, Spain
C.I.R.I.—EDUSTUDIO

who had grown rich in the wake of the Muslim conquests. In order to embarrass Ali they demanded that he bring the murderers of 'Uthmān to trial, and when he rejected their request, a rebellion against him was instigated in which two prominent Meccans along with 'Ā'ishah, Muḥammad's widow and the daughter of Abū Bakr, the first caliph, took a leading part. This rebellion, known as the Battle of the Camel (the camel ridden by 'Ā'ishah), was quelled. A second rebellion was on the point of being crushed when its leader, Mu'āwiyah, a kinsman of 'Uthmān and the governor of Syria, averted defeat by proposing arbitration. 'Alī saw through the stratagem but was forced by his army to accept adjudication, which greatly weakened his position. Soon, moreover, he had to fight some of the very people who had earlier forced him to accept arbitration but now denounced it. Known as Khawārīj (Seceders), they were defeated by 'Alī in the Battle of Nahrawān. Meanwhile, Mu'āwiyah followed an aggressive policy, and by the end of 660 'Alī had lost control of Egypt and of the Hejaz. While praying in a mosque at Kūfah in Iraq, 'Alī was struck with a poisoned sword by a Khārījite, intent on avenging the men slain at Nahrawān. Two days later 'Alī died and was buried near Kūfah.

'Alī's political discourses, sermons, letters, and sayings, collected by ash-Sharīf ar-Raḍī (d. 1015) in a book entitled *Nahj al-balāghah* ("The Road of Eloquence") with commentary by Ibn Abī al-Ḥadīd (d. 1258), are well known in Arabic literature. (I.K.P.)

'Alī THE GREAT (western African monarch): see Sonni 'Alī.

Ali, Muhammad, original name CASSIUS MARCELLUS CLAY (b. Jan. 17, 1942, Louisville, Ky., U.S.), American professional boxer, the first fighter to win the heavyweight championship three separate times.

As an amateur boxer, Clay attracted notice in 1960 by winning the Amateur Athletic Union light heavyweight and Golden Gloves heavyweight championships. He won a gold medal

Muhammad Ali (right) fighting Ernie Terrell, 1967
UPI Compix

in the light heavyweight division at the 1960 Olympic Games in Rome. He turned professional soon afterward and became world heavyweight champion by defeating Sonny Liston, who retired after six rounds, on Feb. 25, 1964. He successfully defended his title nine times from 1965 to 1967 and was universally recognized as champion after outpointing World Boxing Association (WBA)

champion Ernie Terrell in 15 rounds on Feb. 6, 1967. Ali often proclaimed his invincibility in doggerel verse and made the boast "I am the greatest!" his personal slogan.

In 1964 he joined the Nation of Islam (Black Muslims)—adopting a Muslim name—and in 1967 he refused, on religious grounds, to submit to induction into the armed forces. He was subsequently convicted of violating the Selective Service Act and in consequence barred from the ring and stripped of his title, although the conviction was ultimately reversed by the U.S. Supreme Court in 1971.

Ali had meanwhile resumed boxing in 1970 and had defeated two other title contenders, but on March 8, 1971, in a Madison Square Garden bout billed as the "Fight of the Century" he lost a 15-round decision to the heavyweight champion, Joe Frazier. For nearly three years Ali fought other title contenders, including Jerry Quarry, Floyd Patterson (making a brief comeback attempt), Joe Bugner, and Ken Norton. Finally Ali won a unanimous decision over Frazier on Jan. 28, 1974, that led to his meeting with the new champion, George Foreman, on Oct. 30, 1974, in Kinshasa, Zaire (now Democratic Republic of the Congo). His eighth-round knockout of Foreman in this fight regained for Ali the undisputed world heavyweight title. An Academy Award-winning film, *When We Were Kings* (1996) documents the bout in Zaire, which Don King promoted as the "Rumble in the Jungle."

Over the next 30 months, at the peak of his popularity as champion, Ali fought nine times in bouts that showed him to be a courageous fighter but a fighter on the decline. The most notable of these bouts occurred on Oct. 1, 1975, when Ali and Joe Frazier met in the Philippines to do battle for the third time. In what is regarded by many as the greatest prize-fight of all time (the "Thrilla in Manila"), Ali was declared the victor when Frazier's corner called a halt to the bout after 14 brutal rounds. (Ed.)

The final performances of Ali's ring career were sad to behold. In 1978, after defending his title successfully 10 times, he lost it to Leon Spinks, a novice boxer with an Olympic gold medal but only seven professional fights to his credit. Seven months later, Ali regained the championship with a 15-round victory over Spinks. Then he retired from boxing, but two years later made an ill-advised comeback and suffered a horrible beating at the hands of Larry Holmes in a bout that was stopped after 11 rounds. The final ring contest of Ali's career was a loss by decision to Trevor Berbick in 1981.

Ali's place in boxing history as one of the greatest fighters ever is secure. His final record of 56 wins and 5 losses with 37 knockouts has been matched by others, but the quality of his opponents and the manner in which he dominated during his prime place him on a plateau with boxing's immortals. Ali's most tangible ring assets were speed, superb footwork, and the ability to take a punch. But perhaps more important, he had courage and all the other intangibles that go into making a great fighter.

Ali's later years have been marked by physical decline. Damage to his brain caused by blows to the head have resulted in slurred speech, slowed movement, and other symptoms of Parkinson syndrome. However, his condition differs from chronic encephalopathy, or dementia pugilistica (which is commonly referred to as "punch drunk" in fighters), in that he does not suffer from injury-induced intellectual deficits.

There has been an evolution of Ali's religious views. In the mid-1970s, he began to study the Qur'an seriously and turned to Orthodox Islam. His earlier adherence to the teachings of Elijah Muhammad (e.g., that white people are "devils" and there is no heaven or hell) were replaced by a spiritual embrace of all people

and preparation for his own afterlife. In 1984 Ali spoke out publicly against the separatist doctrine of Louis Farrakhan.

Ali married his fourth wife, Lonnie (née Yolanda Williams), in 1986. He has nine children, most of whom have chosen to avoid the spotlight of which Ali was so fond. One of his daughters, however, Laila Ali, is pursuing a career as a professional boxer. While her skills are limited, she has benefited from the fact that the Ali name is still financially viable.

In 1996 Ali was chosen to light the Olympic flame at the start of the XXIV Olympiad in Atlanta, Georgia. The outpouring of goodwill that accompanied his appearance confirmed his status as one of the most beloved athletes in the world. (T.H.)

BIBLIOGRAPHY. Thomas Hauser, *Muhammad Ali: His Life and Times* (1991), and Mike Marqusee, *Redemption Song. Muhammad Ali and the Spirit of the Sixties* (1999), are biographies. Elliot J. Gorn (ed.), *Muhammad Ali: The People's Champ* (1995), collects conference papers tracing Ali's impact outside of boxing.

'Alī ar-Riḍā, in full ABŪ AL-ḤASAN IBN MŪSĀ IBN JA'FAR 'ALĪ AR-RiḌĀ (b. 765/768/770, Medina, Arabia [now in Saudi Arabia]—d. 818, Ṭūs, Iran), eighth imam of the Twelver Shī'ites, noted for his piety and learning until 817, when the caliph al-Ma'mūn, in an attempt to heal the division between the majority Sunnites and the Shī'ites, appointed him his successor. The appointment aroused varying reactions—few of them, even among the Shī'ites, wholly favourable—and Iraq, already irritated by al-Ma'mūn's transfer of the capital from Baghdad to Merv and by other offenses, rose up in rebellion. Al-Ma'mūn gradually changed his policy. The court party set out from Merv for Baghdad, and on the way 'Alī ar-Riḍā died, after a brief illness, at Ṭūs. Shī'ite historians attribute his death to poison, possibly administered by the caliph himself. His shrine (*mashhad*) at Ṭūs became a pilgrimage place and gave its name to the city (Mashhad, or Meshed, in Iran). Many miracles are attributed to 'Alī ar-Riḍā by the Shī'ites.

'Alī Gauhar: see Shāh 'Ālam II.

Ali Haji bin Raja Amhad, Raja (b. c. 1809, Penyengat, Riau, East Indies [now in Indonesia]—d. c. 1870, Riau), Bugis-Malay prince who, as a scholar and historian, led a renaissance in Malay letters in the mid-19th century.

As a youth Raja Ali accompanied his father on a mission to Batavia (now Jakarta) and on a pilgrimage to Mecca, and by the age of 32 he was joint regent of Lingga for its young Malay sultan.

Raja Ali, a man of affairs, was also a religious and literary scholar and did much to establish Riau as the intellectual centre of the Malay world in the mid-19th century. His own writings include several didactic texts, such as *Muqaddimah fi intizām* (1857; "Introduction to Order") on the duties of kings, a Johnsonian dictionary of Malay usage, *Kitab Penge-tahuan Bahasa* (c. 1869; "Book of Linguistic Knowledge"), and the historical work *Silsilah Melayu dan Bugis* (1865; "Malay and Bugis Genealogy"). His most outstanding contribution to learning, however, is the history begun by his father that he rewrote and expanded as the *Tuhfat al-Nafis* (c. 1866; "Precious Gift"), which remains an invaluable source for the history of the Malay Peninsula, Borneo, and Sumatra.

'Alī ibn Būyeh (Būyid founder): see 'Imād ad-Dawlah.

Ali Khan, Liaquat: see Liaquat Ali Khan.

Āli Paşa, Mehmed Emin (b. March 5, 1815, Constantinople, Ottoman Empire [now Istanbul, Tur.]—d. Sept. 7, 1871, Constantinople), Ottoman grand vizier (chief minister) distinguished for his westernizing reform policies.

Together with Mustafa Reşid Paşa and Fuad Paşa, he was a main figure of the Tanzimat (Reorganization) period (1839–c. 1870) in Ottoman history.

The son of a shopkeeper, Âli Paşa entered government service as a boy. Without formal education, he acquired some knowledge of French, and in 1836 he accompanied a diplomatic mission to Vienna—the first of a series of diplomatic assignments that culminated in his appointment as ambassador to London in 1841. After his return he became foreign minister under Mustafa Reşid Paşa and took part in the congresses of Vienna (1855) and Paris (1856). He served as grand vizier in 1852, 1855–56, 1858–59, 1861, and 1867–71.

Âli Paşa resisted the sultan's efforts to limit the powers of the grand vizierate; he settled the troubles in Serbia and in Moldavia-Walachia by peaceful means; and, in 1868, he pacified the Cretan revolt by the grant of a measure of local self-government. He was one of the most zealous advocates of friendship with France and Great Britain during the reigns of the sultans Abdülmejid I and Abdülaziz.

Ali Paşa Tepelenë, byname LION OF JANINA (b. 1744, Tepelenë, Albania, Ottoman Empire—d. Feb. 5 [Jan. 24, Old Style], 1822, Janina, Ottoman Empire [now Ioánnina, Gr.]), Albanian brigand who, by murder and intrigue, became pasha, or provincial governor, of Janina from 1788. He extended his capricious rule within the Ottoman Empire over much of Albania and Macedonia, Epirus, Thessaly, and the Morea.

His father, Veli, bey of Tepelenë, died a poor man when Ali was 14. His mother, Khamco, formed a brigand band to restore the political and material fortunes of the family, and Ali became a notorious brigand leader. After service with the pasha of Negroponte (Euboea), he joined the wealthy pasha of Delvino, whose daughter he married in 1768. Becoming lieutenant to the derbend-pasha of Rumelia, he policed the highroads, enriched himself, and sent presents to Constantinople. He was rewarded with the pashalik of Trikkala and, after a series of murders and intrigues, obtained that of Janina. His son Veli took over Trikkala and later the Morea, while another son, Mukhtar, became pasha of Lepanto. Though constantly thwarted by the Christian Souliots, whom he finally subdued in 1803, Ali obtained control of the Gulf of Arta and took the ports of Butrinto, Preveza, and Vonitsa. He also gained control of the pashaliks of Elbasan, Delvino, Berat, and Valona (Vlore).

By murders and extortions, he increased his wealth and, by intriguing with Greeks and Albanians, extended his authority over beys and townships. Though appointed viceroy of Rumelia, he repeatedly failed to carry out the orders of the Ottoman sultan, to whom he sent plausible excuses and many presents. Indeed, he acted as an independent sovereign and was treated as such by the British and French, with whom he plotted, hoping to establish Janina as a sea power. By 1819 the sultan, Mahmud II, who intended to centralize the government of his empire, was determined to remove Ali and sanctioned his assassination. Ali tried to save himself but, deserted by his sons and allies, was finally shot down.

Alia, Ramiz (b. Oct. 18, 1925, Shkodër, Albania), president of Albania (1982–92) and head of the communist Party of Labour of Albania (1985–91), renamed the Socialist Party in 1991.

The son of Muslim parents from the Albanian-speaking region of Kosovo in Yugoslavia, Alia attended a French secondary school in Tiranë. During World War II he joined the communist-led National Liberation Movement, becoming a member of the Albanian Communist Party in 1943. At age 19 he was appointed a political commissar, with the rank

of lieutenant colonel, in a combat division of the Albanian Partisan forces.

Immediately after the war he occupied leadership posts in the party's youth organization and in its Office of Propaganda and Agitation, and he was elected a member of the Central Committee in 1948 (when the Communist Party was renamed the Party of Labour). After completing advanced studies in the Soviet Union in 1954, Alia rose rapidly under party boss Enver Hoxha's patronage, serving as minister of education from 1955 to 1958. He became a candidate member of the party's powerful Politburo in 1956, and in 1961 he joined Hoxha's inner circle by becoming a full member of the Politburo and a member of the party's Secretariat.

As the party's chief spokesman on ideological and cultural issues, Alia played a prominent role in bitter disputes over the "revisionism" of Yugoslavia, the Soviet Union, and China—three communist allies from which Hoxha broke away in 1948, 1961, and 1978, respectively. At home Alia led campaigns to purge the artistic and intellectual communities of "bourgeois humanism" and other "alien influences" that he felt threatened Albania's independence and the purity of its official Marxist-Leninist ideology.

Alia became titular head of state in 1982 when he was elected president by the People's Assembly, and he became effective ruler of Albania upon his election as the party's first secretary two days after Hoxha's death in April 1985. Alia expanded ties with neighbours in western as well as eastern Europe in order to acquire foreign exchange, technology, and technical expertise. Faced with chronic inefficiencies in both industry and agriculture, he also instituted limited economic reforms and relaxed the party's grip on Albanian society. This liberal policy led to the unexpected electoral successes of democratic parties. On April 3, 1992, he resigned as president.

In 1993 Alia, along with other leading communist officials, was convicted of corruption and sentenced to nine years in prison. He was released in 1995, and his conviction was overturned in 1997.

Aliákmon River, Modern Greek ALIÁKMON POTAMÓS, river, the longest in Greek Macedonia. The river's total length is 185 miles (297 km). Rising in the Grámmos Mountains of the eastern Pindus Range on the Albanian frontier, the Aliákmon River flows southeast and is joined by a tributary, sometimes also called the Aliákmon, which rises near the Albanian border. After collecting the drainage of Lake Kastorías, its flow is confined to narrow gorges during much of its middle course along the base of the easternmost Pindus. Near Siátista it receives the Pramorítsa River and, farther south, the Venétikos. Swinging around the southern end of the Voúrinós Mountains, the Aliákmon is forced into a wide loop toward the northeast by the northeast-southwest-trending Kamvoúnia massif.

Emerging from between the Vérmion and Piéria mountains, the Aliákmon traverses the Thessaloníki (Salonika) plain, through which it apparently was navigable by small ships in the Middle Ages; but today a hydroelectric dam south of Véroia is a barrier to river traffic. Near Véroia the Aliákmon is joined by a last tributary, the Moglenítsas, which drains the entire western Thessaloníki plain; together they debouch into the upper Gulf of Thérmai on the Aegean Sea. Formerly called by its Macedonian name, Vistrítsa (Bistrítsa), the Aliákmon has served as a natural line of defense against invaders from the north, most recently in 1941 during World War II, when a New Zealand brigade was able to hold it briefly against the German forces invading Greece.

Alicante, *provincia*, in Valencia *comunidad autónoma* ("autonomous community"), southeastern Spain. It was formed in 1833 from parts

of the historical *provincias* of Valencia and Murcia. The barren mountain terrain of the north and northwest stands in contrast to the densely populated southern fertile coastal plain, which is watered by the Segura River.

The *provincia's* principal products are wines and liquors, fruits, vegetables, and fish. Locally produced almonds and *turrone* (nougat) have made the names of Alicante (*q.v.*: the provincial capital) and the towns of Alcoy and Jijona well known. The salt industry at Torrevieja is the largest in Spain. The tourist trade has also become very important. Area 2,264 square miles (5,863 square km). Pop. (2003 est.) 1,632,349.

Alicante, port city, capital of Alicante *provincia*, in Valencia *comunidad autónoma* ("autonomous community"), southeastern Spain. It is located on Alicante Bay of the Mediterranean Sea. Founded as Akra-Leuka ("White Summit") by Phocæan Greeks (from the west coast of Asia Minor) in 325 BC, the city was captured in 201 BC by the Romans, who called it Lucentum. Under Moorish domination, which lasted from 718 to 1249, it was called Al-Akant. It was later incorporated into the kingdom of Aragon and was besieged by the French in 1709 and by the Federalists of Cartagena in 1873.

The city is dominated by Benacantil Hill (721 feet [220 m]) and the citadel of Santa Bárbara (1,000 feet [305 m]), the earliest foundations of which date from 230 BC. Arrabal Roig, the old quarter, overlooks the bay from heights known as the Balcón del Mediterráneo. Notable landmarks in Alicante include the Baroque town hall (1701–60), the Church of Santa María (14th century), and the Renaissance collegiate church of San Nicolás de Bari (18th century).

Alicante serves as the commercial port of Madrid and has excellent road, rail, and air transportation facilities. Wine, raisins, vegetables, and esparto grass (all exported) and tomatoes, bricks, cigarettes, aluminum utensils, furniture, and embroideries are its main products. Its mild climate makes it a winter resort, and the beaches of the Costa Blanca (part of the Mediterranean coast) attract tourists. Pop. (2001 est.) 380,357.

alicatado, mosaic formed of polygonal, coloured glazed tiles. Made up into geometric patterns, they have been used mostly for paving Spanish and Moorish patios but also

Alicatados in the Tower of Comares, the Alhambra, Granada, Spain
Arquivo Mas, Barcelona

for wall surfaces. The expansion of the lands under Christian control in Spain in the 13th century led to a mixture of Gothic and Islāmic styles (known as the Mudéjar style), in which *alicatado* was much used by Spanish craftsmen. These traditional patterns continue to be used, especially where Spanish or Arabic influences are strong.

Alice Springs, town, Northern Territory, Australia. It is the main focus of the Centre, a region of approximately 100,000 square miles (260,000 square km) of central Australia that includes large areas of desert and rocky ridges. Alice Springs lies on the intermittent Todd

Aboriginal artists batik painting, Alice Springs
Bill Bachman

River and the Stuart Highway, 1,028 road miles (1,654 km) north of Adelaide and 954 miles (1,535 km) south of Darwin. The town originated in 1871 as a station on the Overland Telegraph Line, which crossed the MacDonnell Ranges through Heavitree Gap. The town was declared in 1890 under the name Stuart, after the explorer John McDouall Stuart; the current name was adopted in 1933.

Alice Springs is now the northern terminus of the Central Australia Railway, which was extended from Oodnadatta in 1929. The rail line and the cross-continental Stuart Highway have made the town a major shipping point for beef cattle, freight, and minerals (gold, copper, wolfram [tungsten], mica). Irrigation allows limited fruit and dairy farming.

Tourism is of prime importance; during the mild winter months (May to September) thousands flock to the town, which has become an exploration base for the Centre. They may also attend such celebrations as horse and camel races and Henley-on-Todd, a "boat race" on the dry riverbed in which the boats are carried by runners. The town has a residential college for Aboriginals and is a centre of Aboriginal art and research. Once the capital of the short-lived Territory of Central Australia (1926–31), Alice Springs is a regional headquarters for the Royal Flying Doctor Service and the School of the Air (public education by radio for Outback children). Its original telegraph station has been designated a historical reserve. Pop. (2001 prelim.) 267,990.

alicyclic compound, in chemistry, any of a large class of organic compounds in which three or more atoms of the element carbon are linked together in a ring. The bonds between pairs of adjacent atoms may all be of the type designated single bonds (involving two electrons), or some of them may be double or triple bonds (with four or six electrons, respectively); six-membered rings for which a system of alternating single and double bonds may be envisioned, however, belong to another important class (aromatic compounds), distinguished from the alicyclic compounds by a characteristically different pattern of chemical reactivity. Those alicyclic compounds in which the ring contains three or four carbon atoms are less stable than the compounds having larger rings, because the angles formed by adjacent covalent bonds are smaller than is necessary for maximum effectiveness. In the larger rings all the bond angles have the preferred value (about 109.5°); consequently, the atoms in the ring do not lie in one plane. Similar restrictions on the angles in double and triple bonds affect the stability of alicyclic compounds containing such bonds.

alien, in national and international law, a foreign-born resident who is not a citizen by virtue of parentage or naturalization and who is still a citizen or subject of another country.

In early times, the tendency was to look upon the alien as an enemy and to treat him as a criminal or outlaw. Aristotle, probably reflecting a common view in the ancient world, saw non-Greeks as barbarous people who were slaves "by nature." The *jus gentium* of the Roman law applied to both citizens and foreigners and tended to favour the idea that aliens had rights; humanity toward aliens was also fostered, in theory at least, by the Christian idea of the unity of all persons in the church. The legal and ideological expression of humanity toward the alien, however, is generally a relatively modern development.

As sovereign national states began to develop in modern times, founders of international law asserted that natural rights were vested in all persons, without regard to citizenship or alienage—rights of which they ought not to be deprived by civilized societies or their governments. There was no general agreement on the content or scope of these natural rights as they affected aliens, but the existence of some minimum standard of civilized treatment was asserted. The minimum standard, it was conceded, did not include the right of the alien to own realty or to engage in gainful professions. To meet this situation, states entered into treaties that provided that each of the contracting states would treat the nationals of the other state on an equal footing with its own nationals in the admission into trades and professions, ownership or possession of property, access to courts, enjoyment of liberty of conscience, and freedom of worship. Some treaties do not purport to extend to aliens, however, rights that are by municipal law reserved exclusively to nationals of the country; thus, municipal law, rather than conventional international law, is actually controlling. In particular, the desire of nations to protect citizens in their jobs, professions, and businesses against both unemployment and competition is a very strong force restricting the latitude of aliens.

The common economic needs of nations, on the other hand, have had some liberalizing effects on the status of aliens. The treaty constituting the European Community, for instance, provides that citizens of member states shall be free to reside in any signatory country that offers them employment; wages and working conditions are to be the same for citizens and aliens. This treaty may in time serve as a model to raise the so-called minimum standards in the treatment of aliens.

Under U.S. federal law, beginning in 1940, all aliens have had to register. In 1965 a new law provided for phasing out by 1968 the immigration quota system based on national origins that had been in effect, with modifications, since 1921. U.S. immigration is now subject to a worldwide numerical ceiling and a system of preferences based on occupation and relationship to U.S. citizens.

Aliens who are admitted legally to the United States may be so certified and granted "green cards" that entitle them to rights that include employment. But they are still subject to limitations under local laws. The U.S. Supreme Court held, for example, that municipalities may require police officers to be U.S. citizens (1982); "Aliens are by definition those outside the community" of those under self-government.

The alien in the United States is afforded a large measure of economic opportunity; he may invoke the writ of habeas corpus; in criminal proceedings he is entitled to the guarantees of the Bill of Rights; and his property cannot be taken without just compensation. But to remain in the country "is not his right, but is a matter of permission and tolerance." As long as the alien is in the United States, the

Constitution is his protection; but Congress, not the Constitution, decides whether or not he is to remain.

Alien and Sedition Acts (1798), four internal security laws passed by the U.S. Congress, restricting aliens and curtailing the excesses of an unrestrained press, in anticipation of an expected war with France. After the XYZ Affair (1797), war appeared inevitable. Federalists, aware that French military successes in Europe had been greatly facilitated by political dissidents in invaded countries, sought to prevent such subversion in the United States and adopted the Alien and Sedition Acts as part of a series of military preparedness measures.

The three alien laws, passed in June and July, were aimed at French and Irish immigrants, who were mostly pro-French. These laws raised the waiting period for naturalization from 5 to 14 years, permitted the detention of subjects of an enemy nation, and authorized the chief executive to expel any alien he considered dangerous. The Sedition Act (July 14) banned the publishing of false or malicious writings against the government and the inciting of opposition to any act of Congress or the president—practices already forbidden by state statutes and the common law but not by federal law. The federal act reduced the oppressiveness of procedures in prosecuting such offenses but provided for federal enforcement.

The acts were the mildest wartime security measures ever taken in the United States, and they were widely popular. Jeffersonian Republicans vigorously opposed them, however, in the Virginia and Kentucky Resolutions, which the other state legislatures either ignored or denounced as subversive. Only one alien was deported, and only 25 prosecutions, resulting in 10 convictions, were brought under the Sedition Act. With the war threat passing and the Republicans winning control of the federal government in 1800, all the Alien and Sedition Acts expired or were repealed during the next two years.

Alien Registration Act of 1940 (U.S.): see Smith Act.

alienation, in social sciences, the state of feeling estranged or separated from one's milieu, work, products of work, or self. Despite its popularity in the analysis of contemporary life, the idea of alienation remains an ambiguous concept with elusive meanings, the following variants being most common: (1) *powerlessness*, the feeling that one's destiny is not under one's own control but is determined by external agents, fate, luck, or institutional arrangements, (2) *meaninglessness*, referring either to the lack of comprehensibility or consistent meaning in any domain of action (such as world affairs or interpersonal relations) or to a generalized sense of purposelessness in life, (3) *normlessness*, the lack of commitment to shared social conventions of behaviour (hence widespread deviance, distrust, unrestrained individual competition, and the like), (4) *cultural estrangement*, the sense of removal from established values in society (as, for example, in intellectual or student rebellions against conventional institutions), (5) *social isolation*, the sense of loneliness or exclusion in social relations (as, for example, among minority group members), and (6) *self-estrangement*, perhaps the most difficult to define and in a sense the master theme, the understanding that in one way or another the individual is out of touch with himself.

Recognition of the concept of alienation in Western thought has been similarly elusive. Although entries on alienation did not appear in major social science reference books until the 1930s, the concept had existed implicitly or explicitly in the classical sociological works of the 19th and early 20th centuries by such authors as Karl Marx, Émile Durkheim, Fer-

dinand Tönnies, Max Weber, and Georg Simmel.

Perhaps the most famous use of the term was by Marx, who spoke of alienated labour under capitalism: work was compelled rather than spontaneous and creative; workers had little control over the work process; the product of labour was expropriated by others to be used against the worker; and the worker himself became a commodity in the labour market. Alienation consisted of the fact that workers did not gain fulfillment from work.

Marxism, however, represents only one stream of thought concerning alienation in modern society. A second stream, which is considerably less sanguine about the prospects for de-alienation, is embodied in the theory of "mass society." Observing the dislocations brought about by industrialization in the 19th and early 20th centuries, Durkheim and Tönnies—and eventually Weber and Simmel as well—each, in his own way, documented the passing of traditional society and the consequent loss of the sense of community. Modern man was isolated as he had never been before—anonymous and impersonal in an urbanizing mass, uprooted from old values, yet without faith in the new rational and bureaucratic order. Perhaps the clearest expression of this theme is contained in Durkheim's notion of "anomie" (from Greek *anomia*, "lawlessness"), a social condition characterized by rampant individualism and the disintegration of binding social norms. Both Weber and Simmel carried the Durkheimian theme further. Weber emphasized the fundamental drift toward rationalization and formalization in social organization; personal relations became fewer, and impersonal bureaucracy became larger. Simmel emphasized the tension in social life between the subjective and personal, on the one hand, and the increasingly objective and anonymous, on the other.

The definitions of alienation given above—powerlessness, meaninglessness, normlessness, cultural estrangement, social isolation, and self-estrangement—can serve only as a rough guide because there can be radically different conceptions of the idea within any one of the categories. Thus, with respect to self-estrangement, one can be "out of touch" with oneself in several quite different ways. Furthermore, writers have differed not only in their definitions but also in the assumptions that underlie these definitions. Two such contrasting assumptions are the normative and the subjective. First, those who held most closely to the Marxian tradition (for example, Herbert Marcuse, Erich Fromm, Georges Friedmann, and Henri Lefebvre) treated alienation as a normative concept, as an instrument for criticizing the established state of affairs in the light of some standard based on human nature, "natural law," or moral principle. In addition, Marxian theorists insisted upon alienation as an objective condition quite independent of individual consciousness—hence, one can be alienated at work irrespective of one's feelings about the work experience. Alternatively, some writers emphasized that alienation is a social-psychological fact: it is the experience of powerlessness, the sense of estrangement. Such an assumption is often found in descriptions of deviant behaviour and in the work of Robert K. Merton and Talcott Parsons.

Many attempts to measure and test the incidence of alienation in various populations (such as urban dwellers or assembly line workers) have yielded ambiguous results that challenge the usefulness of alienation as a conceptual tool for social science research. Some social scientists have concluded that the concept is essentially philosophical.

Alienus, Aulis Caecina (Roman general): see Caecina Alienus, Aulus.

Aligarh, also called KOIL, or KOL, city, west-central Uttar Pradesh state, northern India. It

lies southeast of Delhi. The city itself is usually called Koil, or Kol; Aligarh is the name of a nearby fort. The city is an agricultural trade centre; the processing of agricultural products and manufacturing are also important. Aligarh Muslim University (1875) and its affiliated colleges are located there, as are a number of other degree colleges. Another old fort, the Dor fortress (1524), now in ruins, lies at the city's centre; its site is occupied by an 18th-century mosque. The city also contains tombs of Muslim saints. Wheat, barley, and other crops are grown in the surrounding area. Pop. (1991) 480,520.

alignment, monument consisting of multiple rows of large upright stones, primarily located in Brittany and built during Neolithic and Early Bronze times. See megalith.

alignment chart (applied mathematics): see nomogram.

alimentary canal, also called DIGESTIVE TRACT, pathway by which food enters an animal and solid wastes are expelled. In mammals the alimentary canal includes the mouth, pharynx, esophagus, stomach, small and large intestines, and anus. See digestion.

alimentary paste, a shaped and dried dough prepared from semolina, farina, wheat flour, or a mixture of these with water or milk and with or without egg or egg yolk. See pasta.

alimony, in divorce law, compensation owed by one spouse to the other for financial support after divorce. Alimony aims at support of the one spouse, not punishment of the other. In some places, the term means simply a property settlement irrespective of future support. Alimony has traditionally been granted from husbands to wives but has occasionally been granted from wives to husbands.

Alimony obligations were first imposed by the Egyptians, Greeks, and Hebrews. The practice helped to avoid feuds with the divorced wife's relatives. Under the Code of Hammurabi, a Mesopotamian husband divorcing his wife without cause had to forfeit a piece of silver. Similarly, Roman law under Justinian I demanded a forfeiture of gold from the guilty spouse in a divorce.

In England, alimony was purely a creation of statute—probably arising out of the medieval church's belief that divorce could not terminate the obligations of marriage in the eyes of God. Scandinavian countries treat husband and wife as equals in divorce suits, allowing reciprocal claims for injury. Some countries—e.g., Russia, Austria, Belgium, and Romania—allow divorce as a normal cancellation of contract, with financial questions being settled by mutual agreement.

Alimony is either temporary, for support and expenses during the lawsuit, or permanent, for support thereafter. Temporary alimony is designed to enable one party to initiate or defend the divorce suit. The granting of temporary or permanent alimony is within the court's discretion, as are the frequency and amounts of payments.

Alinsky, Saul (David) (b. Jan. 30, 1909, Chicago, Ill., U.S.—d. June 12, 1972, Carmel, Calif.), American social organizer who stimulated the creation of numerous activist citizen and community groups.

After college training in archaeology and criminology, Alinsky worked as a criminologist in Illinois for eight years. In 1938, he undertook his first community organizing campaign in a working-class area of Chicago; the result was the Back of the Yards Council, which became a prototype for a generation of community organizations. In 1940, Alinsky founded the Industrial Areas Foundation and trained cadres of organizers in his techniques. Following wartime service in several federal agencies, Alinsky and his IAF team carried their techniques to communities throughout

the country; the Community Service Organization in California provided early training for Cesar Chavez, who went on to found the United Farm Workers of America.

In his home town of Chicago, Alinsky accomplished one of his most notable successes with The Woodlawn Organization, one of the first successful efforts in the country to organize black inner-city residents.

Alinsky wrote the first of his three books, *Reveille for Radicals* (1946), while serving a term in jail; his other books were *Rules for Radicals* (1971) and a biography of John L. Lewis (1949). He continued his organizing activities up to the time of his death.

aliphatic compound, any chemical compound belonging to the organic class in which the atoms are not linked together to form a ring. One of the major structural groups of organic molecules, the aliphatic compounds include the alkanes, alkenes, and alkynes, and substances derived from them—actually or in principle—by replacing one or more hydrogen atoms by atoms of other elements or groups of atoms.

Alipore, also spelled ALĪPUR, town, West Bengal state, northeastern India. A southern suburb of Calcutta included within the city municipality, it has major industries, including printing and bookbinding, cement manufacture, oilseed milling, and general engineering works. Alipore is the site of zoological-horticultural gardens and of Belvedere House, onetime residence of the former British lieutenant governor of Bengal and now the location of the National Library. The town has a college affiliated with the University of Calcutta.

Alipur Duār, city, northeastern West Bengal state, northeastern India, just north of the Kalyāni River. Connected by road with Jalpaiguri, the city is an important market centre for rice, tobacco, and jute; an annual agricultural produce and stock fair is held there. Rice milling is an important industry. Alipur Duār was declared a municipality in 1951. Pop. (1991) 65,421.

Aliquippa, city, Beaver county, western Pennsylvania, U.S. It lies along the Ohio River, just northwest of Pittsburgh. Settled about 1750 as a post for trade with Delaware, Iroquois, and Shawnee Indians, it was first known as Logstown and later renamed for "Queen" Aliquippa, probably an Iroquois. After the French and Indian War (1754–63), the Indian peoples lost title to the land, and Logstown was deserted. White settlers came again in the 1770s, and sawmilling and gristmilling were early industries. During the winter of 1793–94, General Anthony ("Mad Anthony") Wayne trained his troops at a site across the river before moving into western Ohio to defeat the British-supported Northwest Indian Confederation at the Battle of Fallen Timbers (Aug. 20, 1794). Aliquippa grew rapidly after 1900 with the establishment of steel mills in the area. Although some structural steel is still being produced, most of the steelmaking operations have been torn down, leaving the city with restricted employment opportunities and an aging population. Aliquippa consolidated in 1928. Pop. (2000) 11,734.

Alişar Hüyük, site of an ancient Anatolian town southeast of Boğazköy in central Turkey. Thorough and extensive excavations there by the Oriental Institute of the University of Chicago (1927–32) were the first systematic stratigraphic investigations on the Anatolian plateau. In the long succession of strata revealed at Alişar Hüyük—from Chalcolithic (c. 4000–c. 2600 BC) to Phrygian (c. 1200–

c. 700 BC)—the only era that was not represented was the Hittite, from the 17th to the 13th century BC.

The mound consisted of an off-centre top elevation, known as the citadel, and a sloping terrace. The earliest habitation was probably in the Late Chalcolithic Age and Early Copper Age. Later, in the Bronze Age (c. 3000–c. 2000 BC), two different cultures appear to have occupied the site; the remains may represent an intrusion of foreign invaders, possibly Indo-European Hittites or related tribes, who were rapidly assimilated. Among the remains of the native Anatolian culture were a number of 19th-century "Cappadocian tablets," the records of Assyrian merchant colonists who lived at Alişar Hüyük.

After the 13th century BC, the mound was the site of a Phrygian fortress, with a walled section on the slope below. The settlement survived perhaps to the 6th century BC and was finally destroyed by fire.

Alismatales, also called **ALISMALES**, the water-plantain order of flowering plants, belonging to the class Liliopsida (monocotyledons; characterized by a single seed leaf). Most species are aquatic and grow submerged or partially exposed to the air in marshes and other freshwater habitats. Many are aquatic weeds that hinder irrigation and navigation, though others provide important habitats for fish and help stabilize shorelines. Although of little economic importance, these herbaceous (nonwoody) plants, by forming complex communities with other aquatic and emergent stream-bank plants, bring about vegetational succession; a pond may fill up with plant parts and silt to become a biological landfill, which eventually supports land plants.

The order Alismatales comprises three families. The Butomaceae, consisting of a single genus and species (*Butomus umbellatus*), is used in landscaped water gardens. The three genera of Limnocaritaceae are tropical, and some species grow well in tropical fish aquariums. The Alismataceae, with 14 genera and about 90 species, is found in the North Temperate Zone and the tropics. The members of Alismataceae are notable for developing latex channels (containing milky juice) in their stems and leaves. Water plantain (*Alisma plantago-aquatica*), arrowhead (*Sagittaria*), and burhead (*Echinodorus*) are of frequent occurrence.

Most members of the Alismatales order possess short stems and are rooted in mud with only the leaves visible above water level. In some species even the leaves are submerged and fail to differentiate into the familiar lamina (blade) and petiole (leaf stalk) of land plants. Emergent leaf blades are often triangular or arrowhead-shaped, and some attractive types have been reproduced in artistic designs. *Alisma*, which gives the order its name, produces heart-shaped leaves noted for contoured venation and delicate crossveins.

Succulence is characteristic of Alismatales, and air spaces may occupy 80 percent of the volume of internal tissues of the leaf and root. The vascular system, which consists of the xylem (water-conducting tissues) and phloem (food-conducting tissues), is rather inconspicuous and plays only a minor role in supporting the plant.

A potential flower cluster (inflorescence) arises as a specialized stem from the flattened vegetative stem at the juncture of a leaf base. As it elongates above water, a succession of flower buds forms and develops in a sequence of sepals and petals. In the Alismatales, the small petals attract beetles, butterflies, and flies, which are the main pollinators. After pollination and fertilization, an ovule becomes the seed. In some species, seeds are shed when the

ovary matures into a fruit and eventually ruptures, as in *Butomus*. In other groups, such as the Alismataceae, seeds are liberated only after the ovary wall disintegrates in the water.

Alismatidae, subclass of herbaceous monocotyledonous flowering plants found in aquatic or wet regions. There are three or four orders within the subclass—Alismatales (or Alismales), Hydrocharitales, Najadales, and Triuridales—containing 16 families and more than 400 species.

A brief treatment of the Alismatidae follows. For full treatment, see **MACROPAEDIA: Angiosperms**.

The plants' flowers vary from large and showy to small and inconspicuous. The flowers may be regular or irregular and are arranged in inflorescences, generally as a raceme or spike. The perianth is organized in multiples of three sepals and three petals or is reduced to the point of absence in some members of the subclass. The leaves are simple and are arranged alternately along the stem, though they may be opposite or whorled in some species. The leaf blade is parallel-veined and often sheathed at the base, though the blade may be reduced or completely lost in some members.

The orders Alismatales, Hydrocharitales, and Najadales are considered to be closely related, but the order Triuridales is unique and, in some classifications, of uncertain affiliation. The subclass as a whole is thought by some to be the most archaic member of the monocotyledonous angiosperms.

Alito, Samuel A., Jr., in full **SAMUEL ANTHONY ALITO, JR.** (b. April 1, 1950, Trenton, N.J., U.S.), associate justice of the U.S. Supreme Court from 2006.

Alito earned a bachelor's degree (1972) from Princeton University and a law degree (1975) from Yale University. He served as assistant to the U.S. solicitor general (1981–85), deputy assistant to the U.S. attorney general (1985–87), and U.S. attorney for the district of New Jersey (1987–90). In 1990 he was appointed by Pres. George Bush to serve as a judge on the U.S. Court of Appeals for the Third Circuit, where he established a strongly conservative judicial record. Alito voted to uphold restrictions on abortion rights and to allow local governments to display religious symbols (such as Nativity scenes) during holidays, and he voted to strike down federal gun-control legislation. In 2005 he was appointed associate justice of the U.S. Supreme Court by Pres. George W. Bush; he was confirmed (58–42) by the U.S. Senate the following year.

Alitus (Lithuania): see **Alytus**.

aliyah, plural **ALIYAHs**, **ALIYOTH**, or **ALIYOT**, Hebrew 'ALIYA ("going up"), in Judaism, the honour accorded to a worshiper of being called up to read an assigned passage from the Torah (first five books of the Bible). Because the passage assigned for each sabbath-morning service is subdivided into a minimum of seven sections, at least seven different persons are called up for these readings. An additional reader is called up to repeat part of the final reading and to recite the *Haftarah* (a reading from the prophetic books of the Bible). At certain times throughout the year (e.g., fast days, festivals), there are fewer Torah readings and they may not be subdivided into more than the statutory number.

If a cohen (a direct descendant of Aaron, the first priest) and a Levite (a member of the priestly tribe of Levi) are present, it is their privilege to be called up for the first and second readings, respectively. Normally, therefore, an Israelite (ordinary worshiper) may not be so honoured until the third reading.

By the 14th century it had become customary to appoint a trained reader to do the actual reading to avoid embarrassing those whose knowledge of Hebrew was inadequate. The persons who were called up, therefore, merely

presided during the reading and recited the appropriate blessings. The practice of selling the *aliyah* has been discontinued.

In modern times, *aliyah* has also been used to designate the "going up" to Israel of immigrants from other lands, just as in former times it meant going up to the Holy Land.

alizarin, also spelled **ALIZARINE**, a red dye originally obtained from the root of the common madder plant, *Rubia tinctorum*, in which it occurs combined with the sugars xylose and glucose. The cultivation of madder and the use of its ground root for dyeing by the complicated Turkey red process were known in ancient India, Persia, and Egypt; the use spread to Asia Minor about the 10th century and was introduced into Europe in the 13th.

Laboratory methods of preparing alizarin from anthraquinone were discovered in 1868, and, upon commercial introduction of the synthetic dye in 1871, the natural product disappeared from the market for textile dyes, though natural rose madder is still occasionally used, as a lake, for artists' colours. The application of alizarin to cotton, wool, or silk requires prior impregnation of the fibre with a metal oxide, or mordant. The shade produced depends on the metal present: aluminum yields a red; iron, a violet; and chromium, a brownish red.

Alkalai, Judah ben Solomon Hai (b. 1798, Sarajevo, Bosnia, Ottoman Empire [now Bosnia and Herzegovina]—d. 1878, Jerusalem, Palestine), Sephardic rabbi and an early advocate of Jewish colonization of Palestine.

Alkalai was taken to Jerusalem at an early age, and there he was reared and educated for the rabbinate. At 25 he went to Semlin, in Croatia, as a rabbi and found himself teaching Hebrew to the young men of his congregation, whose native language was Ladino. He wrote two books in that language, in the first of which he argued that a physical "return to Israel" (i.e., to Eretz Yisra'el, the Holy Land in Palestine) was a precondition for redemption (salvation), instead of the symbolic "return to Israel" by means of repentance and resuming the ways of God. This doctrine was unacceptable to Orthodox Jews and generated much controversy. His second book was a refutation of the heated attacks directed at his proto-Zionist views.

After the Damascus Affair, an anti-Semitic outburst of 1840, Alkalai took to admonishing Jews that the event was part of a divine design to awaken Jews to the reality of their condition in exile. Believing that Jews should migrate nowhere but to Palestine, he traveled in England and about Europe seeking support for such emigration, founding organizations wherever he went, but these came to naught. Finally in 1871 he left his congregation at Semlin and went to Palestine, where he created a new organization, a society for settlement. It too failed. But Alkalai's writings—he was an inveterate pamphleteer—did have some effect, as did one book—his first in Hebrew—*Goral Ladonai* (1857; "A Lot for the Lord"). These and his personal migration helped pave the way for the coming Zionism of Theodor Herzl and others.

alkali, any of the soluble hydroxides of the alkali metals—i.e., lithium, sodium, potassium, rubidium, and cesium. Alkalies are strong bases that turn litmus paper from red to blue; they react with acids to yield neutral salts; and they are caustic and in concentrated form are corrosive to organic tissues. The term alkali is also applied to the soluble hydroxides of such alkaline-earth metals as calcium, strontium, and barium and also to ammonium hydroxide. The term was originally applied to the ashes of burned sodium- or potassium-bearing plants, from which the oxides of sodium and potassium could be leached.

The manufacture of industrial alkali usually

refers to the production of soda ash (Na_2CO_3 ; sodium carbonate) and caustic soda (NaOH ; sodium hydroxide). Other industrial alkalies include potassium hydroxide, potash, and lye. The production of a vast range of consumer goods depends on the use of alkali at some stage. Soda ash and caustic soda are essential to the production of glass, soap, miscellaneous chemicals, rayon and cellophane, paper and pulp, cleansers and detergents, textiles, water softeners, certain metals (especially aluminum), bicarbonate of soda, and gasoline and other petroleum derivatives.

People have been using alkali for centuries, obtaining it first from the leachings (water solutions) of certain desert earths. In the late 18th century the leaching of wood or seaweed ashes became the chief source of alkali. In 1775 the French Académie des Sciences offered monetary prizes for new methods for manufacturing alkali. The prize for soda ash was awarded to the Frenchman Nicolas Leblanc, who in 1791 patented a process for converting common salt (sodium chloride) into sodium carbonate. The Leblanc process dominated world production until late in the 19th century, but following World War I it was completely supplanted by another salt-conversion process that had been perfected in the 1860s by Ernest Solvay of Belgium. Late in the 19th century, electrolytic methods for the production of caustic soda appeared and grew rapidly in importance.

In the Solvay, or ammonia-soda process (*q.v.*) of soda ash manufacture, common salt in the form of a strong brine is chemically treated to eliminate calcium and magnesium impurities and is then saturated with recycling ammonia gas in towers. The ammoniated brine is then carbonated using carbon dioxide gas under moderate pressure in a different type of tower. These two processes yield ammonium bicarbonate and sodium chloride, the double decomposition of which gives the desired sodium bicarbonate as well as ammonium chloride. The sodium bicarbonate is then heated to decompose it to the desired sodium carbonate. The ammonia involved in the process is almost completely recovered by treating the ammonium chloride with lime to yield ammonia and calcium chloride. The recovered ammonia is then reused in the processes already described.

The electrolytic production of caustic soda involves the electrolysis of a strong salt brine in an electrolytic cell. (Electrolysis is the breaking down of a compound in solution into its constituents by means of an electric current in order to bring about a chemical change.) The electrolysis of sodium chloride yields chlorine and either sodium hydroxide or metallic sodium. Sodium hydroxide in some cases competes with sodium carbonate for the same applications, and in any case the two are interconvertible by rather simple processes. Sodium chloride can be made into an alkali by either of the two processes, the difference between them being that the ammonia-soda process gives the chlorine in the form of calcium chloride, a compound of small economic value, while the electrolytic processes produce elemental chlorine, which has innumerable uses in the chemical industry. For this reason the ammonia-soda process, having displaced the Leblanc process, has found itself being displaced, the older ammonia-soda plants continuing to operate very efficiently while newly built plants use electrolytic processes.

In a few places in the world there are substantial deposits of the mineral form of soda ash, known as natural alkali. The mineral usually occurs as sodium sesquicarbonate, or trona ($\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$). The United States produces much of the world's natural alkali from vast trona deposits in underground mines in Wyoming and from dry lake beds in California.

alkali feldspar, any of several common silicate minerals that often occur as variously coloured, glassy crystals. They are used in the manufacture of glass and ceramics; transparent, highly coloured, or iridescent varieties are sometimes used as gemstones. The alkali feldspars are primarily important as constituents of rocks; they are very widespread and abundant in alkali and acidic igneous rocks (particularly syenites, granites, and granodiorites), in pegmatites, and in gneisses. The alkali feldspars may be regarded as mixtures of sodium aluminosilicate ($\text{NaAlSi}_3\text{O}_8$) and potassium aluminosilicate (KAlSi_3O_8). Both the sodium and potassium aluminosilicates have several distinct forms, each form with a different structure. The forms stable at high temperatures include high-albite (sodium) and sanidine and high-sanidine (potassium); these have a random distribution of aluminum and silicon atoms in their crystal structure. Low-temperature forms include albite (sodium) and orthoclase and microcline (potassium); these have an ordered arrangement of such atoms. If specimens of the high-temperature varieties are rapidly cooled, the random distribution is preserved. In the Earth's crust the alkali feldspars display a range of ordering from the fully random distribution of high-sanidine, through sanidine and orthoclase, to the fully ordered distribution of microcline. *See* feldspar.

alkali flat, also called *SALINA*, or *SALT FLAT*, a playa, or dried-out desert lake, especially one containing high concentrations of precipitated dry, glistening salts. The term is generally limited to flats in the western United States, the most famous being the Bonneville Salt Flats (*q.v.*) west of Salt Lake City, where automobile speed records are set.

alkali metal, any of the six chemical elements that make up Group I of the periodic table—namely, lithium (Li), sodium (Na), potassium (K), rubidium (Rb), cesium (Cs), and francium (Fr). The alkali metals are so called because they form alkalies (*i.e.*, strong bases capable of neutralizing acids) when they combine with other elements.

A brief treatment of the alkali metals follows. For full treatment, *see* *MACROPAEDIA: Chemical Elements*. *See also* *MICROPAEDIA* for entries on each member of this group.

The only members of the alkali metal family that are relatively abundant in the Earth's crust are potassium and sodium. These two were the first alkali metals to be isolated (1807). Alkali metals bear little resemblance to the more familiar metals such as iron and copper. They are silver-white in colour, malleable, and soft enough to cut with a knife. They are the most chemically active of all metals, readily forming ions with a single positive charge. This property is a result of their atoms having only a single, highly mobile electron in the outermost shell. Alkali metals react rapidly, sometimes violently, with both oxygen and water. Because of their reactivity, they always occur in nature in combination with other elements as simple and complex compounds. Pure alkali metals can be extracted from such compounds by the electrolysis of molten salts or hydroxides. Another process, known as thermal reduction, is also employed to obtain lithium and cesium.

alkaline-earth metal, any of the six chemical elements that comprise Group IIa of the periodic table. The elements are beryllium (Be), magnesium (Mg), calcium (Ca), strontium (Sr), barium (Ba), and radium (Ra).

A brief treatment of the alkaline-earth metals follows. For full treatment, *see* *MACROPAEDIA: Chemical Elements*. *See also* *MICROPAEDIA* for entries on each member of this group.

The designation "earth" for these metals derives from the Middle Ages when alchemists referred to substances that were insoluble in

water and unchanged by fire as earths. Those earths, such as lime, that bore a resemblance to the alkalines (*e.g.*, soda ash and potash) were called alkaline earths. By the early 1800s it became apparent that the earths, formerly regarded as elements, were in reality compounds of a metal and oxygen—*i.e.*, oxides. The metals whose oxides comprise the alkaline earths subsequently came to be known as the alkaline-earth metals. Magnesium, calcium, strontium, and barium were isolated as impure metals for the first time in 1808 by the English chemist Sir Humphry Davy.

The alkaline-earth metals are basically grayish white in colour. They all are malleable but vary widely in hardness. Beryllium, for example, is hard enough to cut glass; barium, by contrast, is as soft as lead. Like other metals, the alkaline-earth elements are good conductors of electricity. Their melting points and boiling points, though varying in an irregular fashion, are higher than those of the corresponding alkali metals. The atoms of the alkaline-earth elements have a similar electronic structure, which consists of a pair of electrons in the outermost shell. These electrons are removed from their respective atoms relatively easily, and this ionization is the distinguishing chemical property of the alkaline-earth metals. These elements readily combine with most oxides and many nonmetals and thus never occur as pure metals in nature.

Magnesium and calcium are the only abundant alkaline-earth elements in the crust of the Earth. They also are the most commercially important members of the family.

Consult the INDEX first

alkaline phosphatase, enzyme that is normally present in high concentrations in growing bone and in bile. It is essential for the deposition of minerals in the bones and teeth. Alkaline phosphatase deficiency is a hereditary trait called hypophosphatasia, which results in bone deformities. In severe cases, the deficiency leads to early death from infection. Alkaline phosphatase is also present in the blood and is an important clinical diagnostic indicator for several illnesses, including chronic myelogenous leukemia.

alkaloid, any of a class of naturally occurring organic nitrogen-containing bases. Alkaloids have diverse and important physiological effects on humans and other animals. Well-known alkaloids include morphine, strychnine, quinine, ephedrine, and nicotine.

Alkaloids are found primarily in plants and are especially common in certain families of flowering plants. More than 3,000 different types of alkaloids have been identified in a total of more than 4,000 plant species. In general, a given species contains only a few kinds of alkaloids, though both the opium poppy (*Papaver somniferum*) and the ergot fungus (*Claviceps*) each contain about 30 different types. Certain plant families are particularly rich in alkaloids; all plants of the poppy family (Papaveraceae) are thought to contain them, for example. The Ranunculaceae (buttercups), Solanaceae (nightshades), and Amaryllidaceae (amaryllis) are other prominent alkaloid-containing families. A few alkaloids have been found in animal species, such as the New World beaver (*Castor canadensis*) and poison-dart frogs (*Phyllobates*). Ergot and a few other fungi also produce them.

The function of alkaloids in plants is not yet understood. It has been suggested that they are simply waste products of plants' metabolic processes, but evidence suggests that they may serve specific biological functions. In some plants, the concentration of alkaloids increases

just prior to seed formation and then drops off when the seed is ripe, suggesting that alkaloids may play a role in this process. Alkaloids may also protect some plants from destruction by certain insect species.

The chemical structures of alkaloids are extremely variable. Generally, an alkaloid contains at least one nitrogen atom in an amine-type structure—*i.e.*, one derived from ammonia by replacing hydrogen atoms with hydrogen-carbon groups called hydrocarbons. This or another nitrogen atom can be active as a base in acid-base reactions. The name alkaloid ("alkali-like") was originally applied to the substances because, like the inorganic alkalis, they react with acids to form salts. Most alkaloids have one or more of their nitrogen atoms as part of a ring of atoms, frequently called a cyclic system. Alkaloid names generally end in the suffix *-ine*, a reference to their chemical classification as amines. In their pure form most alkaloids are colourless, nonvolatile, crystalline solids. They also tend to have a bitter taste.

Interest in the alkaloids stems from the wide variety of physiological effects (both wanted and unwanted) they produce in humans and other animals. Their use dates back to ancient civilizations, but scientific study of the chemicals had to await the growth of organic chemistry, for not until simple organic bases were understood could the intricate structure of the alkaloids be unraveled. The first alkaloid to be isolated and crystallized was the potent active constituent of the opium poppy, morphine, in 1805–06.

Alkaloids are often classified on the basis of their chemical structure. For example, those alkaloids that contain a ring system called indole are known as indole alkaloids. On this basis, the principal classes of alkaloids are the pyrrolidines, pyridines, tropanes, pyrrolizidines, isoquinolines, indoles, quinolines, and the terpenoids and steroids. Alternatively, alkaloids can be classified according to the biological system in which they occur. For example, the opium alkaloids occur in the opium poppy (*Papaver somniferum*). This dual classification system actually produces little confusion because there is a rough correlation between the chemical types of alkaloids and their biological distribution.

The medicinal properties of alkaloids are quite diverse. Morphine is a powerful narcotic used for the relief of pain, though its addictive properties limit its usefulness. Codeine, the methyl ether derivative of morphine found in the opium poppy, is an excellent analgesic that is relatively nonaddictive. Certain alkaloids act as cardiac or respiratory stimulants. Quinidine, which is obtained from plants of the genus *Cinchona*, is used to treat arrhythmias, or irregular rhythms of the heartbeat. Many alkaloids affect respiration, but in a complicated manner such that severe respiratory depression may follow stimulation. The drug lobeline (from *Lobelia inflata*) is safer in this respect and is therefore clinically useful. Ergonovine (from the fungus *Claviceps purpurea*) and ephedrine (from *Ephedra* species) act as blood-vessel constrictors. Ergonovine is used to reduce uterine hemorrhage after childbirth, and ephedrine is used to relieve the discomfort of common colds, sinusitis, hay fever, and bronchial asthma.

Many alkaloids possess local anesthetic properties, though clinically they are seldom used for this purpose. Cocaine (from *Erythroxylon coca*) is a very potent local anesthetic. Quinine (from *Cinchona* species) is a powerful anti-malarial agent that was formerly the drug of choice for treating that disease, though it has been largely replaced by less toxic and more effective synthetic drugs. The alkaloid tubocurarine is the active ingredient in the South

American arrow poison, curare (obtained from *Chondodendron tomentosum*), and is used as a muscle relaxant in surgery. Two alkaloids, vincristine and vinblastine (from *Vinca rosea*), are widely used as chemotherapeutic agents in the treatment of many types of cancer.

Nicotine obtained from the tobacco plant (*Nicotiana tabacum*) is the principal alkaloid and chief addictive ingredient of the tobacco smoked in cigarettes, cigars, and pipes. Some alkaloids are illicit drugs and poisons. These include the hallucinogenic drugs mescaline (from *Anhalonium* species) and psilocybin (from *Psilocybe mexicana*). Synthetic derivatives of the alkaloids morphine and lysergic acid (from *C. purpurea*) produce heroin and LSD, respectively. The alkaloid coniine is the active component of the poison hemlock (*Conium maculatum*). Strychnine (from *Strychnos* species) is another powerful poison.

Special methods have been developed for isolating commercially useful alkaloids. In most cases, plant tissue is processed to obtain aqueous solutions of the alkaloids. The alkaloids are then recovered from the solution by a process called extraction, which involves dissolving some components of the mixture with reagents. Different alkaloids must then be separated and purified from the mixture. Chromatography may be used to take advantage of the different degrees of adsorption of the various alkaloids on solid material such as alumina or silica. Alkaloids in crystalline form may be obtained using certain solvents.

alkalosis, abnormally low level of acidity, or high level of alkalinity, in the body fluids, including the blood. Metabolic alkalosis (also called alkalemia) results from either acid loss (which may be caused by severe vomiting or by the use of potent diuretics [substances that promote production of urine]) or bicarbonate gain (which may be caused by excessive intake of bicarbonate or by the depletion of body fluid volume). Respiratory alkalosis results from hyperventilation usually caused by anxiety. Hyperventilation may also be caused by asthma, congestive heart failure, pulmonary embolism, and pneumonia. *Compare* acidosis.

Alkan, Valentin, in full CHARLES-HENRI-VALENTIN ALKAN, original name CHARLES-HENRI-VALENTIN MORHANGE (b. Nov. 30, 1813, Paris, France—d. March 29, 1888, Paris), French pianist-composer, one of the leading virtuosos of the 19th century and one of the most enigmatic figures in 19th-century music.

Alkan was born to Jewish parents, and all of his siblings (five brothers and a sister) also assumed the surname Alkan and were musicians. Valentin drew notice at the age of seven, when he won the first of many first prizes at the Paris Conservatory. By the age of 17 he had established a reputation as a virtuoso pianist. As a young man he moved in a circle of friends that included George Sand, Victor Hugo, Frédéric Chopin, and Franz Liszt, but for long periods of time beginning in his 20s he withdrew from society and concert performance and devoted himself to composing music. His music, difficult and often unorthodox, displays considerable ingenuity and imagination in advancing the possibilities of keyboard technique; in this respect Ferruccio Busoni, an Italian composer and pianist, considered him to be excelled only by Liszt and Johannes Brahms. Alkan himself felt that he was overshadowed by Liszt. In his rare concert appearances he preferred to play the works of 18th-century composers (then out of fashion), rather than his own compositions. His numerous works (composed mostly for piano and pedal piano) include preludes and studies in all the major and minor keys; 12 pieces, *Les mois* (*The Months*); the sonata *Les quatre âges*; and the *Piano Concerto in C Sharp Minor*. César Franck transcribed several of his pieces for organ.

alkane (chemistry): *see* paraffin hydrocarbon.

alkaptonuria, rather rare (one in 200,000 births) inherited disorder of protein metabolism characterized by an inability of the body to metabolize the amino acids tyrosine and phenylalanine. In the normal metabolic pathway of tyrosine, homogentisic acid is converted to malaclylactocacetate in the liver by the enzyme homogentisate 1,2-dioxygenase. This enzyme is not active in individuals who have alkaptonuria. Except for a blackening of the urine due to the buildup and oxidation of homogentisic acid, this disorder has no clinical manifestations until the affected person is in his twenties or thirties, when deposits of ochre pigments begin to appear in various fibrous connective tissues of the body. The pigment, bound to collagen fibres in the deeper layers of joint cartilage and intervertebral disks (the fibrous pads between adjacent bones of the spine), causes these tissues to lose their normal resiliency and become brittle. The erosion of the abnormal cartilage leads to a progressive degenerative disease of the joints, which usually becomes manifest by the fourth decade of life. Usually, the intervertebral disks become thinned and calcified first, and later the knees, shoulders, and hips are affected.

Alkaptonuria is compatible with normal life expectancy. In some cases arteriosclerosis has been described; however, it is not known whether this is a manifestation of the disease or coincidental. No effective treatment is available for the underlying metabolic disorder.

alkene (chemistry): *see* olefin.

Alkmaar, gemeente (commune), Noordholland provincie, northwestern Netherlands. It lies along the North Holland Canal, 6 miles (10 km) east of the North Sea.

The English missionaries Willibrord and Adalbert preached Christianity in the district in the 8th century. A fishing village in the 10th century, Alkmaar (meaning "all marsh," or "all sea") was chartered in 1254 and was the capital of Kennemerland, an early possession of the counts of Holland. It was sacked by the Frisians in 1132 and again by a combined force of Frisians and Gelderlanders in 1517. Alkmaar became an important trade centre after 1564; when the surrounding swamps were reclaimed. The town successfully withstood a Spanish siege in 1573 to become a symbol of Dutch resistance (commemorated by a monument in Victorie Park). Under the Convention of Alkmaar (1799), a Russo-British army withdrew from the Netherlands after an unsuccessful campaign to overthrow the Batavian Republic.

A market centre for cattle, dairy products, and vegetables, the town is also a tourist centre noted for its Friday cheese market (Kaasmarkt), held from April to October. Alkmaar's

Cheese market, Alkmaar, Neth.
Malak—Shostal

manufactures include furniture, clothing, paper, and church organs. The most notable landmarks are the Weighhouse (1582, rebuilt from a 14th-century chapel), with a carillon tower, and St. Lawrence's Church (1470-1520), with one of the oldest organs in The Netherlands (1511). Other historic buildings include the town hall (1520), the 16th-century Sonoy Court, and several almshouses. Pop. (1993 est.) 92,421.

alkylation, in petroleum refining, chemical process in which light, gaseous hydrocarbons are combined to produce high-octane components of gasoline. The light hydrocarbons consist of olefins such as propylene and butylene and isoparaffins such as isobutane. These compounds are fed into a reactor, where, under the influence of a sulfuric-acid or hydrofluoric-acid catalyst, they combine to form a mixture of heavier hydrocarbons. The liquid fraction of this mixture, known as alkylate, consists mainly of isooctane, a compound that lends excellent antiknock characteristics to unleaded gasolines.

Alkylation units were installed in petroleum refineries in the 1930s, but the process became especially important during World War II, when there was a great demand for aviation gasoline. It is now used in combination with fractional distillation, catalytic cracking, and isomerization to increase a refinery's yield of automotive gasoline.

alkyne (chemistry): *see* acetylene.

All-America team, group of a season's outstanding U.S. college football players, first picked by Caspar Whitney in 1889 and publicized in a magazine called *This Week's Sport*. The All-America team is usually associated with Walter C. Camp, who collaborated with Whitney from 1891 to 1896 and then published his own selections from 1897 to 1924, mostly in *Collier's* magazine. Camp's reputation as football player, coach, and rules maker made his selections generally accepted. When Camp died in 1925, *Collier's* engaged Grantland Rice, a prominent football writer, to continue the annual selection.

Even before 1900, other football devotees began making their own All-America choices. The number of these selections increased as the popularity of football grew. Rice and *Collier's* began the practice of compiling their selections from the findings of a nationwide board of the American Football Coaches Association. The major American news services, Associated Press and United Press International, also use the findings of representatives scattered throughout the country to choose All-America teams, as does the Football Writers Association of America.

All-America teams are now also chosen in such sports as baseball, basketball, swimming, and track and field and consist of athletes from colleges, high schools, and prep schools.

all-around (gymnastics): *see* combined exercises.

All-England Championships, byname WIMBLEDON CHAMPIONSHIPS, internationally known lawn tennis championships played annually in London at Wimbledon (*q.v.*).

All Fools' Day: *see* April Fools' Day.

all-fours, family of card games dating back to 17th-century England and first mentioned in *The Complete Gamester* of Charles Cotton in 1674. Like whist, all-fours was at first a popular game with the lower classes, but in the 15th century it came to be accepted into middle-class homes.

Each player is dealt six cards, three at a time. The top card of the remaining pack is then exposed to establish the trump. The player to the dealer's left, called the eldest hand, may dispute the trump, in which case the dealer may agree to "run the cards" (trade three from

the pack for three from each hand) and then establish a new trump.

Play is led by the eldest hand, and each player either follows suit or plays trump if he is able; otherwise, he follows with any card of ascending rank, regardless of suit. The highest trump or, if no trumps were played, the highest card in the led suit takes the trick. Each trick is led by the previous trick's winner. Points are awarded at hand's end, and 7 points wins the game.

All-fours is so named because there are four scoring categories: high (scored by the player who plays the highest trump card); low (scored by the player who plays the lowest trump); jack (knave of trump suit, scored by the dealer if he turns it as trump or by the player winning it in a trick); and game (a plurality of high-card points won in tricks, with each 10 counting 10, jacks 1, queens 2, kings 3, and aces 4). The game is played by two or three players or by two sets of partners.

The game was called seven-up, from the 7 winning points, when it first was introduced to North America in the early 1700s. That game was replaced in popularity by pitch, which introduced bidding: each player has one chance to bid the number of points he thinks he can win, with 4 the high bid. The high bidder pitches (leads first), and the suit of this card becomes trump for the hand. If the pitcher fails to fulfill his contract, he is set back the number of points bid. At times, pitch is augmented by the rule called smudge, by which the player meeting his bid of 4 wins the game at once. From this comes the variant game smudge, where collecting all 4 points in one hand, regardless of the bid, wins the game.

All India Muslim League: *see* Muslim League.

All-India Trade Union Congress (AITUC), India's second largest trade union federation after the Indian National Trade Union Congress. The AITUC was formed by the Indian National Congress (the central organ of the independence movement) in 1920 to represent India at the International Labour Organisation of the League of Nations. During the 1920s British communists, in trying to organize trade unions, gained control of much of the federation; several opposing factions subsequently split away. The communists gained complete control during World War II but lost some popular support when they chose to support the war effort along with Britain after the Soviet Union entered the war. Since then, AITUC leaders have been split into reformist and revolutionary factions. The AITUC is affiliated with the World Federation of Trade Unions.

All Nippon Airways Co., Ltd., Japanese ZEN NIPPON KŪYU, the largest domestic air carrier in Japan, and one of the largest in the world. The company was founded in 1952 and is headquartered in Tokyo. Under the Japanese government's strict regulation of civil aviation, All Nippon Airways was basically restricted to carrying passengers and freight on Japan's major domestic routes, while Japan Air Lines basically monopolized the country's overseas air service. All Nippon began making chartered flights to other East Asian countries in the 1970s, however, and in the late 1980s it began regular service on major international routes, taking advantage of certain deregulation measures in the industry. The company has subsidiaries involved in aircraft maintenance, repair, and refueling; other subsidiaries operate hotels and provide package tours for All Nippon's passengers.

all-or-none law, a physiological principle that relates response to stimulus in excitable tissues. It was first established for the contraction of heart muscle by the American physiologist Henry P. Bowditch in 1871. Describing the relation of response to stimulus,

he stated, "An induction shock produces a contraction or fails to do so according to its strength; if it does so at all, it produces the greatest contraction that can be produced by any strength of stimulus in the condition of the muscle at the time." It was believed that this law was peculiar to the heart and that the other highly specialized and rapidly responding tissues—skeletal muscle and nerve—responded in a different way, the intensity of response being graded according to the intensity of the stimulus. It has been established, however, that the individual fibres of both skeletal muscle and nerve respond to stimulation according to the all-or-none principle. This does not mean that the size of response is immutable, because functional capacity varies with the condition of the tissue, and the response to a stimulus applied during recovery from a previous response is subnormal. The size of response, however, is independent of the strength of stimulus, provided this be adequate. The functional response is essentially alike in these specialized tissues—heart, skeletal muscle, and nerve. The response resembles an explosive reaction in that it depletes for a time the available store of energy on which it depends.

All Saints Bay (Brazil): *see* Todos os Santos Bay.

All Saints' Day, in the Christian church, a day commemorating all the saints of the church, both known and unknown, celebrated on November 1 in the Western churches and on the first Sunday after Pentecost in the Eastern churches. Its origin cannot be traced with certainty, and it has been observed on various days in different places. A feast of all martyrs was kept on May 13 in the Eastern church according to Ephraem Syrus (d. c. 373), which may have determined the choice of May 13 by Pope Boniface IV when he dedicated the Pantheon in Rome as a church in honour of the Blessed Virgin and all martyrs in 609. The first evidence for the November 1 date of celebration and of the broadening of the festival to include all saints as well as all martyrs occurred during the reign of Pope Gregory III (731-741), who dedicated a chapel in St. Peter's, Rome, on November 1 in honour of all saints. In 800, All Saints' Day was kept by Alcuin on November 1, and it also appeared in a 9th-century English calendar on that day. In 837 Pope Gregory IV ordered its general observance. In medieval England, the festival was known as All Hallows, and its eve is still known as Halloween.

All Souls' Day, in the Roman Catholic church, a day for commemoration of all the faithful departed, those baptized Christians who are believed to be in purgatory because they have died with the guilt of lesser sins on their souls. It is celebrated on November 2. Roman Catholic doctrine holds that the prayers of the faithful on earth will help cleanse these souls in order to fit them for the vision of God in heaven.

From antiquity certain days were devoted to intercession for particular groups of the dead. The institution of a day for a general intercession on November 2 is due to Odilo, abbot of Cluny (d. 1048). The date, which became practically universal before the end of the 13th century, was chosen to follow All Saints' Day. Having celebrated the feast of all the members of the church who are believed to be in heaven, the church on earth turns, on the next day, to commemorate those souls believed to be suffering in purgatory.

Priests celebrate mass wearing vestments of varying colour—black (for mourning), violet (symbolizing penance), or white (symbolizing the hope of resurrection).

All-Star Game, in American professional baseball, a game between teams of outstanding players chosen from National and American league teams who oppose each other as league against league. Arch Ward, a *Chicago Tribune* sports editor, is credited with promoting the first All-Star Game, which was held in Chicago in 1933 in conjunction with the Century of Progress Exposition. The All-Star Game is held each July; two annual games were played from 1959 to 1962. Most of the gate receipts are donated to the players' pension fund. Similar contests are conducted in American professional football and basketball, as well as on various amateur levels of these and other sports.

All-Union Leninist Communist League of Youth: see Komsomol.

Allāh (Arabic: "God"), the one and only God in the religion of Islām. Etymologically, the name Allāh is probably a contraction of the Arabic *al-Ilāh*, "the God." The name's origin can be traced back to the earliest Semitic writings in which the word for god was *Il* or *El*, the latter being an Old Testament synonym for *Yahweh*. *Allāh* is the standard Arabic word for "God" and is used by Arab Christians as well as by Muslims.

Allāh is the pivot of the Muslim faith. The Muslim holy scripture, the Qur'ān, constantly preaches Allāh's reality, his inaccessible mystery, his various names, and his actions on behalf of his creatures. Three themes preponderate: (1) Allāh is creator, judge, and rewarder; (2) he is unique (*wāḥid*) and inherently one (*aḥad*); and (3) he is omnipotent and all-merciful. God is the "Lord of the Worlds," the most high, "nothing is like unto him," and this in itself is to the believer a request to adore Allāh as protector and to glorify his powers of compassion and forgiveness.

God, says the Qur'ān, "loves those who do good," and two passages in the Qur'ān express a mutual love between God and man, but the Judeo-Christian precept to "love God with all thy heart" is nowhere formulated in Islām. The emphasis is rather on God's inscrutable sovereignty, to which one must abandon oneself. In essence, the "surrender to Allāh" (*islām*) is the religion itself.

Muslim piety has collected, in the Qur'ān and in the Hadith (the sayings of the Prophet Muḥammad), the 99 "most beautiful names" (*al-asmā' al-ḥusnā*) of God, and these names have become objects of devoted recitation and meditation. Among the names of Allāh are the One and Only, the Living One, the Subsisting (*al-Ḥayy al-Qayyūm*), the Real Truth (*al-Ḥaqq*), the Sublime (*al-'Azīm*), the Wise (*al-Ḥakīm*), the Omnipotent (*al-'Azīz*), the Hearer (*as-Samī'*), the Seer (*al-Baṣīr*), the Omniscient (*al-'Alīm*), the Witness (*Shāhid*), the Protector (*al-Wakīl*), the Benefactor (*ar-Raḥmān*), the Merciful (*ar-Raḥīm*), and the Constant Forgiver (*Ghaffūr, Ghaffār*).

At all times there have been freethinkers in Islām, but rare indeed has been the Muslim thinker who has denied the very existence of God. Indeed, the profession of faith (*shahādah*) by which a person is introduced into the Muslim community consists of the affirmation that there is no god but Allāh and that Muḥammad is his prophet. For pious Muslims, every action is opened by an invocation of the divine name (*basmalah*). The formula *inshā'a Allāh*, "if God wills," appears frequently in daily speech. This formula is the reminder of an ever-present divine intervention in the order of the world and the actions of human beings. Muslims believe that nothing happens and nothing is performed unless it is by the will or commandment of Allāh. The personal attitude of a Muslim believer, therefore, is a complete submission to God,

"whom one does not question" but whom one knows according to his (Qur'ānic) word to be a fair judge, at once formidable and benevolent, and the supreme help.

Allahābād, city, southern Uttar Pradesh state, northern India. It is situated at the confluence of the Ganges and Yamuna (Jumna)

Anand Bhawan (formerly Nehru house, now a museum) at Allahābād, Uttar Pradesh, India

Foto Features

rivers. Allahābād stands on the site of ancient Prayāg, a holy city that was comparable in fame to Vārānasi (Benares) and Hardwar. Prayāg's importance in the ancient Buddhist period of Indian history is attested to by the inscriptions on the Pillar of Aśoka, which still stands inside the gateway to the old Allahābād fort (which is situated strategically at the confluence of the two rivers). The site's religious importance persists; each year a festival takes place at the rivers' confluence, and every 12th year a much larger festival, Kumbh Mela, is attended by millions of Hindus.

The present city of Allahābād was founded in 1583 by the Mughal emperor Akbar, who named it al-Ilahābād ("City of God"). It became a provincial capital in the Mughal Empire, and from 1599 to 1604 it was the headquarters of the rebellious prince Salim (later the emperor Jahangir). Outside Allahābād fort is the tomb built for Emperor Jahangir's rebellious son, Khusru. With the Mughal decline, Allahābād changed hands many times before being ceded to the British in 1801. The city was the scene of a great massacre during the 1857 Indian Mutiny against British rule. From 1904 to 1949 the city was the capital of the United Provinces (now Uttar Pradesh). It was a centre of the Indian independence movement and was the home of the Nehru family, whose estate is now a museum.

Primarily an administrative and educational centre, Allahābād has some industry (food processing and manufacturing) and is a marketplace for agricultural products. The administrative and professional sector and the military cantonment are located north of the city proper. The city is a major road and rail centre and is served by a nearby airport. The University of Allahābād (1887) has a number of affiliated colleges, and there is an aviation training centre. The city has several museums. Allahābād has a Government House dating from the British period, Anglican and Roman Catholic cathedrals, and the Jāmi' Masjid, or Great Mosque.

The surrounding area lies entirely on the Ganges Plain. Rice, barley, wheat, and gram (chick-pea) are among the region's chief crops. Pop. (2001 prelim.) city, 990,298; metropolitan area, 1,049,579.

Allais, Maurice (b. May 31, 1911, Paris, France), French economist who was awarded the Nobel Prize for Economics in 1988 for his development of principles to guide efficient pricing and resource allocation in large monopolistic enterprises.

Allais studied economics at the École Polytechnique and then at the National Superior School of Mines of Paris. In 1937 he be-

gan working for the state-owned French mine administration, and in 1944 he became a professor at the National Superior School of Mines. From the 1940s on he directed various government research bodies dealing with economics research. In 1977 he was named an officer of the Legion of Honour.

In Allais's principal works, two massive studies published in the 1940s, he examined the functioning of state-owned monopolies such as national utility companies. He laid the theoretical foundation for determining the prices of these monopolies' products or services in such a way as to offer maximal economic efficiency while still providing optimum social benefits. His principles became a guiding force for planning state enterprises in terms of prices rather than by direct (and often politically determined) regulation. Allais's theories thus offered to large state monopolies the opportunity to apply efficient market-economics principles. His work proved particularly important in view of the growth of state-owned monopolies in the economies of western Europe in the decades following World War II.

Allan, Sir Hugh (b. Sept. 29, 1810, Saltcoats, Ayrshire, Scot.—d. Dec. 9, 1882, Edinburgh), Canadian financier and shipbuilder whose contribution of \$300,000 to the Conservative Party campaign in 1872 precipitated the Pacific Scandal that brought down Sir John Macdonald's government.

Allan emigrated to Canada in 1826 and in 1831 began work for a shipbuilding company in Montreal. By 1839 he was a senior partner, and by 1853 he and his brother Andrew owned their own steamship company, the Allan Line, and conducted shipping between Montreal, Glasgow, and Liverpool. His services to Canadian commerce won him a knighthood in 1871.

In 1872 the Canadian government gave Allan the transcontinental railway charter for his Canadian Pacific Railway. It was later revealed, however, that, as a member of a Chicago financial syndicate, he had subsidized Macdonald's Conservative Party election campaign. The subsequent scandal not only discredited Macdonald's government but also led to the dissolution of Allan's railway company.

allantois, an extra-embryonic membrane of reptiles, birds, and mammals arising as a pouch, or sac, from the hindgut. In reptiles and birds it expands greatly between two other membranes, the amnion and chorion, to serve as a temporary respiratory organ while its cavity stores fetal excretions. In mammals other than marsupials the allantois is intimately associated with the chorion, contributing blood vessels to that structure as it forms—in conjunction with the endometrium, or mucosal lining, of the uterus—the placenta.

Allbutt, Sir Thomas Clifford (b. July 20, 1836, Dewsbury, Yorkshire, Eng.—d. Feb. 22, 1925, Cambridge, Cambridgeshire), English physician, the inventor of the short clinical thermometer. His investigations also led to the improved treatment of arterial diseases.

Allbutt, detail of a portrait by Sir William Orpen

The Mansell Collection

During a 28-year practice in Leeds, Allbutt made valuable clinical studies, primarily of arterial and nervous disorders. In 1866 he introduced the modern clinical thermometer, a welcome alternative to the foot-long instrument that required 20 minutes to register a patient's temperature. In 1871 he published a monograph outlining use of the ophthalmoscope (used to inspect the interior of the eye) as a diagnostic instrument. In 1892 Allbutt accepted a chair of physic at the University of Cambridge, where he spent the rest of his career. Continuing his previous work, he postulated that the painful heart condition angina pectoris originates in the aorta (1894).

Allbutt was also a noted medical historian. Two of his most important publications were *Diseases of the Arteries, Including Angina Pectoris* (1915) and *Greek Medicine in Rome* (1921). His chief contribution to his field was *Systems of Medicine*, 8 vol. (1896–99). He was knighted in 1907.

allée, feature of the French formal garden that was both a promenade and an extension of the view. It either ended in a terminal feature, such as a garden temple, or extended into apparent infinity at the horizon.

Allée bordered by tall, clipped trees, Schönbrunn Palace, Vienna

Dr. Glauboch—Photo Researchers

The *allée* normally passed through a planted bosage (a small wood); in the 17th century the bosage was square-trimmed at the sides and on top; later the sides were trained so high that the free-branching trees within the wood were invisible. As architectural gardening became unfashionable in the 18th century, the trimming of trees ceased, and the straight *allée* gave way to the meandering walk.

Alleghenian orogeny, a mountain-building event that affected the Appalachian Geosyncline in late Paleozoic (Permian) time, from about 290 million to 245 million years ago. The term Appalachian Revolution formerly was applied to this event. The Alleghenian orogeny is most pronounced in the central and southern Appalachians and produced the compressional folding and faulting of the Ridge and Valley Province, the westward thrusting of the Blue Ridge over Valley and Ridge rocks, and folding and minor metamorphism and igneous intrusion in the Piedmont Province. Evidence of the Alleghenian orogeny is less prominent in the northern Appalachians, but late Paleozoic folding and igneous intrusions are present along the east coast of New England and parts of the eastern Maritime Provinces of Canada.

The Alleghenian orogeny may have resulted from the collision of the central and southern Appalachian continental margin with that of North Africa in late Paleozoic time.

Allegheny Mountains, also called ALLEGHENIES, mountainous eastern part of the Allegheny Plateau in the Appalachian Mountains, U.S. The Allegheny range extends south-southwestward for more than 500 miles

Allegheny Mountains in West Virginia
Grant Heilman

(800 km) from north-central Pennsylvania to southwestern Virginia. Rising to Mount Davis (3,213 feet [979 m]; highest point in Pennsylvania) and Spruce Knob (4,862 feet [1,482 m]; highest point in West Virginia), the mountains consist of nearly parallel northeast-southwest ridges that are drained through the gorges cut by the North Branch of the Potomac and the New rivers. Parts of the Monongahela, George Washington, and Jefferson national forests encompass the mountains, which are noted for their scenic beauty. Once forming a barrier to western communication, they are now crossed by many railroads and highways. The name Alleghenies is also used in reference to the Allegheny Plateau (*q.v.*).

Allegheny Plateau, western section of the Appalachian Mountains, U.S., extending southwestward from the Mohawk River valley in central New York to the Cumberland Plateau in southern West Virginia. Generally sloping toward the northwest, the plateau has been dissected by streams to form the Catskill, Allegheny, and other mountain ranges. The Allegheny, Delaware, and Susquehanna rivers drain its northern portion, while the Ohio River system drains the southern part. The plateau is mainly covered by hardwood forest.

With the discovery of coal, a large influx of settlers led to an early breakdown of the isolation of this part of the Appalachians. The regional economy depends heavily upon the extraction of coal, natural gas, and petroleum.

Allegheny River, river rising in the hilly plateau region of Potter county, Pa., U.S., and flowing generally northward for about 80 miles (130 km). The river enters New York state where the Allegheny Reservoir is impounded at Allegheny State Park; turning southwest, it continues for 120 miles (190 km), meandering to the southeast and again southwest and eventually joining the Monongahela River at Pittsburgh to form the Ohio River. In its total length (325 miles [523 km]), it drains an area of 11,700 square miles (30,300 square km). Its chief tributaries are the Kiskiminetas, Clarion, and Conemaugh rivers and Red Bank, Oil, and French creeks. The Allegheny was important for keelboat navigation before the beginning of railway competition in the mid-19th century. Several dams were built (1903–38) to make the river navigable from Pittsburgh to East Brady. Flood-control dams have been built on many of its major tributaries.

allegory, a work of written, oral, or artistic expression that uses symbolic fictional figures and actions to convey truths or generalizations about human conduct or experience.

A brief treatment of literary allegory follows. For full treatment, see MACROPAEDIA: Literature, The Art of.

Like metaphor, an allegory expresses spiritual, psychological, or abstract intellectual concepts in terms of material and concrete objects. In the 13th-century French didactic poem *Roman de la Rose*, for example, most of the details of the garden have a fixed connotation in terms of courtly love; but what may seem the mechanical contrivance of the extended metaphor is redeemed by its imaginative rendering.

In allegorical fictions—especially European medieval morality plays—many of the characters are personifications. Personification is allegorical insofar as it endows a thing or abstraction with human attributes; but it differs from allegory in that the identity of the thing personified is always clearly proclaimed, be it Good Deeds, Gluttony, or Riches.

Allegory both conceals and reveals. When an author ventures into political allegory, he may protect himself by the element of disguise and, at the same time, make satirical revelations through the implied comparison. Thus, in the prologue of the 14th-century English poem *Piers Plowman*, the author, using the story of the mice who were afraid to bell the cat, states his views on the House of Commons' unsuccessful attempt to curb John of Gaunt's depredations. In *Absalom and Achitophel* (1681), John Dryden reveals, under scriptural disguise, the characters of politicians involved in an attempt to alter the succession to the English throne.

Several of these methods are combined by George Orwell in *Animal Farm* (1945), which, under the guise of a fable about domestic animals who take over a farm from their human oppressor, expresses the author's disillusionment with the outcome of the Bolshevik Revolution and shows how one tyrannical system of government in Russia was merely replaced by another. Perhaps the most original use of allegory in the 20th century is to be found in the works of Franz Kafka, whose enigmatic fantasies about the predicament of the individual in an incomprehensible environment are not susceptible of any single or precise interpretation.

allele, also called ALLELOMORPH, any one of two or more genes that may occur alternatively at a given site (locus) on a chromosome. Alleles may occur in pairs, or there may be multiple alleles affecting the expression (phenotype) of a particular trait. If the paired alleles are the same, the organism is said to be homozygous for that trait; if they are different, the organism is heterozygous. A dominant allele will override the traits of a recessive allele in a heterozygous pairing. In some traits, however, alleles may be codominant—*i.e.*, neither acts as dominant or recessive. An example is the human ABO blood system; persons with type AB blood have one allele for A and one for B. (Persons with neither are type O.) See *also* dominance; recessiveness.

Most traits are determined by more than two alleles. Multiple forms of the allele may exist, though only two will attach to the designated gene site during meiosis. Also, some traits are controlled by two or more gene sites. Both possibilities multiply the number of alleles involved. All genetic traits are the result of the interactions of alleles. Mutation, crossing over, and environmental conditions selectively change the frequency of phenotypes (and thus their alleles) within a population.

alleluia: see hallelujah.

allemande, processional couple dance with stately, flowing steps, fashionable in 16th-century aristocratic circles; also an 18th-

century figure dance. The earlier dance apparently originated in Germany but became fashionable both at the French court (whence its name, which in French means "German") and in England, where it was called *almain*, or *almand*. The French dancing master Thoinot Arbeau, author of *Orchésographie* (1588), a principal source of knowledge of Renaissance dance, regarded it as an extremely old dance. Its popularity waned in the 17th century.

In the *allemande* the dancers formed a line of couples, extended their paired hands forward, and paraded back and forth the length of the ballroom, walking three steps, then balancing on one foot; a livelier version used three springing steps and a hop. The music was in $\frac{3}{4}$ time. As a 17th-century musical form, the *allemande* is a stylized version of this dance. In a suite (as in J.S. Bach's *English Suites*) it is normally the first movement.

The 18th-century *allemande* was a figure dance in $\frac{3}{4}$ time for four couples; one of its handholds possibly derived from the earlier *allemande*. The dancers performed intricate turns called *enchainements*, or *passés*, with elaborate interlacings of the arms.

allemontite, the mineral arsenic antimonide (AsSb). It commonly occurs in veins, as at Allemont, Isère, Fr.; Valtellina, Italy; and the Comstock Lode, Nevada. It also is present in a lithium pegmatite at Varuträsk, Swed. Polished sections of most specimens of allemontite show an intergrowth of allemontite with either pure arsenic in a vein occurrence or with nearly pure antimony in a pegmatite occurrence. Homogenous allemontite has also been found at Varuträsk. For detailed physical properties, see native element (table).

Allen, Bog of, Irish *MÓIN ALÚINE*, group of peat bogs between the Liffey and the Shannon rivers in east-central Ireland in Counties Kildare, Offaly, Laoighis, and Westmeath. Some 370 square miles (958 square km) in area, it is developed extensively for fuel for power stations; the cutover land is used for grazing. The bogs are traversed by the Grand and Royal canals, the latter no longer in use. An early monastic site exists within the bog.

Allen, Ethan (b. Jan. 21, 1738, Litchfield, Conn. [U.S.]—d. Feb. 12, 1789, Burlington, Vt., U.S.), soldier and frontiersman, leader of the Green Mountain Boys (*q.v.*) during the U.S. War of Independence.

After fighting in the French and Indian War (1754–63), Allen settled in what is now Vermont. At the outbreak of the American Revolution, he raised his force of Green Mountain Boys (organized in 1770) and Connecticut troops and helped capture the British fort at Ticonderoga, N.Y. (May 10, 1775). Later, as a volunteer in General Philip Schuyler's forces, he conducted a foolhardy attempt to take Montreal (September 1775), in the course of which he was captured by the British and held prisoner until May 6, 1778. Congress gave him the brevet rank of colonel with back pay, but he did not serve in the war after his release. Instead, he devoted his time to local affairs in Vermont, especially working for separate statehood from New York. Failing to achieve this, he attempted to negotiate the annexation of Vermont to Canada.

Allen, Fred, original name JOHN FLORENCE SULLIVAN (b. May 31, 1894, Cambridge, Mass., U.S.—d. March 17, 1956, New York, N.Y.), American humorist whose laconic style, dry wit, and superb timing influenced a generation of radio and television performers.

While working as a stack boy in the Boston Public Library, the young Sullivan came across a book on juggling from which he picked up that craft. He began juggling on amateur entertainment circuits and took the stage

name Fred St. James (later Fred James). He added ventriloquism to his act, performing in touring amateur shows, and then went on a vaudeville tour that took him in 1915 and 1916 to Australia, New Zealand, and Hawaii. When he returned to the United States it was as a professional. He came back to vaudeville, where he turned increasingly to comedy, and adopted his final stage name, Fred Allen, to honour the American Revolution hero Ethan Allen—who, he noted, was no longer using the name. He married a fellow performer, Portland Hoffa, and during the 1920s appeared in a number of revues, such as *The Passing Show*, the *Little Show*, and *Three's a Crowd*.

Allen was an established entertainer when he entered radio in 1932. He was featured on a variety of programs by the Columbia Broadcasting System (CBS) before the advent of his most remembered work, "Town Hall Tonight" (1934–39), which became "The Fred Allen Show" in 1939 and ran until 1949. Allen and Portland Hoffa took the principal roles, along with the residents of "Allen's Alley," a cast of characters including Falstaff Openshaw, Titus Moody, Mrs. Nussbaum, and Senator Claghorn. Allen wrote nearly all of each of the 273 episodes of the program. His movies included *Love Thy Neighbor* (1940), in which he continued his good-natured feud with radio star Jack Benny. His autobiographical book, *Treadmill to Oblivion*, appeared in 1954.

Allen, Gracie: see Burns, George; and Allen, Gracie.

Allen, Hervey, original name WILLIAM HARVEY ALLEN, JR. (b. Dec. 8, 1889, Pittsburgh, Pa., U.S.—d. Dec. 28, 1949, Coconut Grove, Fla.), American poet, biographer, and novelist who had a great impact on popular literature with his historical novel *Anthony Adverse*.

Allen's first published work was a book of poetry, *Ballads of the Border* (1916). During the 1920s he established a reputation as a poet, publishing several more volumes of verse.

Allen was wounded in World War I; the novel *Toward the Flame* (1926) came out of his wartime experience. That same year his authoritative biography *Israfil: The Life and Times of Edgar Allan Poe* was published.

In 1933, after five years of writing, he published *Anthony Adverse*, which was a huge success. Set in Europe during the Napoleonic era, *Anthony Adverse* offered a multitude of characters and picturesque settings within a complex plot. The book's undisguised passages about sex and its considerable length introduced a new standard for popular fiction.

Allen's following novels did not attain the popularity or the critical acclaim of *Anthony Adverse*, although the first three volumes of his planned five-volume series about colonial America (*The Forest and the Fort*, 1943; *Bedford Village*, 1944; *Toward the Morning*, 1948) were widely read. Allen was at work on the fourth volume of the series (*The City in the Dawn*; published posthumously, 1950) at the time of his death.

Consult the INDEX first

Allen, Sir Hugh (Percy) (b. Dec. 23, 1869, Reading, Berkshire, Eng.—d. Feb. 20, 1946, Oxford, Oxfordshire), organist and musical educator who exerted a far-reaching influence on the English musical life of his time.

Allen was an organ scholar at Christ's College, Cambridge, and later held organist's posts at Ely cathedral (1898) and New College, Oxford (1901–18). In 1918 he became director of the Royal College of Music, London, and in the same year professor of music at Oxford. He raised the position of music in the Oxford curriculum and made more adequate provisions for research and teaching, accomplishments that had wide influence elsewhere. He was also noted for his research on Hein-

Sir Hugh Allen, drawing by John Singer Sargent, 1925; in the British Museum

By courtesy of the trustees of the British Museum photograph, J.R. Freeman & Co. Ltd

rich Schütz and J.S. Bach. He conducted the Bach choirs in Oxford (from 1901) and London (1907–20) and was a leading proponent of contemporary English music.

Allen, Sir James (b. Feb. 10, 1855, Adelaide, S.Aus., Australia—d. July 28, 1942, Dunedin, N.Z.), statesman, leader of the New Zealand Reform Party, and minister of defense (1912–20) who was instrumental in the development of New Zealand's navy and expeditionary military force.

Allen was elected to the New Zealand Parliament in 1887, serving as a leader of the opposition from 1892 to 1912. When the Reform Party took office in 1912, he became minister of finance, defense, and education. He introduced the Naval Defence Act (1913), which established a New Zealand division in the Royal Navy. He guided the development of the New Zealand expeditionary force into an effective fighting unit in World War I and, for these services, was knighted in 1917. Continuing as minister of defense in the Reform-Liberal coalition (1915–19), he was responsible for the War Pensions Act (1915) and the conscription bill of 1916. When the leader of the government, W.F. Massey, attended international conferences (1917–19), Allen served as acting prime minister. He was appointed to the posts of minister of finance and of external affairs in 1919.

Allen introduced a repatriation plan for discharged servicemen and guided New Zealand's acquisition of the League of Nations mandate for Western Samoa. He served as high commissioner for New Zealand in London (1920–26) and sat on his country's Legislative Council from 1927 until his retirement in 1938.

Allen, Richard (b. Feb. 14, 1760, Philadelphia, Pa. [U.S.]—d. March 26, 1831, Philadelphia), founder and first bishop of the African Methodist Episcopal Church, a major American denomination.

Soon after Allen was born, to slave parents, the family was sold to a Delaware farmer. At 17 he became a Methodist convert and at 22 was permitted to preach. Two years later (1784), at the first general conference of the Methodist Episcopal Church at Baltimore, Allen was considered a talented candidate for the new denomination's ministry. In 1786 he bought his freedom and went to Philadelphia, where he joined St. George's Methodist Episcopal Church. Occasionally he was asked to preach to the congregation. He also conducted prayer meetings for blacks. Restrictions were placed on the number permitted to attend these meetings, and Allen, dissatisfied, withdrew in 1787 to help organize an independent Methodist Church. In 1787 he turned an old blacksmith shop into the first church for blacks in the United States. His followers were known as Allenites.

In 1799 Allen became the first black to be officially ordained in the ministry of the Methodist Episcopal Church. The organization of the Bethel Society led, in 1816, to the

founding of the African Methodist Episcopal Church, which elected Allen its first bishop.

Allen, Steve, byname of STEPHEN VALENTINE PATRICK WILLIAM ALLEN (b. Dec. 26, 1921, New York, N.Y., U.S.—d. Oct. 30, 2000, Encino, Calif.), pioneer American television entertainer, versatile author, songwriter, and comedian who performed in radio, motion pictures, and theatre, as well as television.

Steve Allen, 1956

© Bettmann/Corbis

Allen's mother was a comedienne, and his father was a singer and foil for her in their vaudeville act. Allen traveled with them while growing up. He became a radio actor while in high school and studied journalism at two colleges before becoming a radio announcer in Phoenix, Ariz., in 1942. He moved west as he gained prominence and began working for the Columbia Broadcasting System (CBS) in Hollywood after a stint as a comedian for a regional network. In 1953 he created the landmark late-evening talk and variety program "The Tonight Show," which aired on the National Broadcasting Company (NBC) network with Allen as host until 1957. "The Tonight Show" provided a showcase for his diverse talents, and thereafter with a succession of hosts it remained a perennial favourite of late-night viewers. Allen was also a prolific songwriter. He composed and wrote lyrics for over 3,000 songs, among them "Picnic," "This Could Be the Start of Something Big," and "Impossible."

Allen, Viola (Emily) (b. Oct. 27, 1869, Huntsville, Ala., U.S.—d. May 10, 1948, New York, N.Y.), American actress, especially famous for her Shakespearean roles and for her roles in *Little Lord Fauntleroy* and *Shenandoah*.

Viola Allen

Library of Congress, Washington, D.C.

Born into a theatrical family, Allen made her debut at age 14 in New York City in the title role of *Esmeralda*. Between 1884 and 1886 she appeared in a variety of modern and Shakespearean plays with the best-known 19th-century actors and in *Little Lord Fauntleroy* and *Shenandoah* (1888–89). Later she toured in *The Rivals* and *The Heir at Law*; starred in *The Christian* (1898); and formed her own Shakespearean theatre company (1903). In 1915 she made her only motion picture, *The White Sister*.

Allen, William (b. 1532, Rossall, Lancashire, Eng.—d. Oct. 16, 1594, Rome [Italy]), English cardinal and scholar who supervised the preparation of the Roman Catholic Douai-Reims translation of the Bible and engaged in intrigues against the Protestant regime of Queen Elizabeth I.

Educated at the University of Oxford, Allen became principal of St. Mary's Hall there in 1556. After the accession of Queen Elizabeth he fell under suspicion for refusing to take an oath acknowledging the Queen as governor of the English church. Further government pressure caused him to leave England in 1565 for Mechelen in the Spanish Netherlands, where he was ordained priest. In 1568 Allen founded at Douai (then in the Spanish Netherlands, now in France) a seminary for training Englishmen as missionary priests. He was president and lecturer of this seminary until 1585, moving with it to Reims in 1578. The school gave its name to the influential Douai-Reims version of the Bible, translated by Gregory Martin under Allen's direction.

Allen also helped found the English college in Rome in 1576. In 1580 he organized the first Jesuit missions to England—where Roman Catholic worship was prohibited—but in subsequent years he despaired of restoring Catholicism to his native country by peaceful means. He therefore called upon King Philip II of Spain to conquer England and assume the English throne; as a consequence he was made cardinal at Philip's request in 1587. But England's defeat of the Spanish Armada (1588) ended Allen's political intrigues. In 1584 he wrote a tract defending English Catholics from charges of treason by William Cecil, Lord Burghley.

Allen, Woody, original name ALLEN STEWART KONIGSBERG, legal name HEYWOOD ALLEN (b. Dec. 1, 1935, Brooklyn, New York, N.Y., U.S.), American motion-picture director, screenwriter, actor, and author, best known for his bittersweet comic films containing elements of parody, slapstick, and the absurd. He was also known as a sympathetic director of women, writing strong and well-defined characters for them. Among his featured performers were Diane Keaton and Mia Farrow, with both of whom he was romantically involved.

Much of Allen's comic material derives from his urban Jewish middle-class background. Intending to be a playwright, Allen began writing stand-up comedy monologues while still in high school. His introduction to show business came a few years later when he was hired to write material for such television comedians as Sid Caesar and Art Carney. In the early 1960s, after several false starts, he acquired a following on the nightclub circuit, performing his own stand-up comedy routines. His comic persona was that of an insecure and doubt-ridden person who playfully exaggerates his own failures and anxieties. Soon Allen began writing and directing plays and films, often also acting in the latter. He appeared in and wrote the screenplay for *What's New, Pussycat?* (1965), and his first play, *Don't Drink the Water*, appeared on Broadway in 1966. He starred in and directed the film *Take the Money and Run* (1969), a farcical comedy about an incompetent would-be criminal. The films that followed—*Bananas* (1971), *Everything You Always Wanted to Know About Sex but Were Afraid to Ask* (1972), and *Sleeper* (1973)—secured his reputation as a major comic filmmaker. In *Love and Death* (1975), a parody of 19th-century Russian novels, critics discerned an increased seriousness beneath the comic surface. This was borne out in Allen's next (directed) film, the award-winning *Annie Hall* (1977), in which the self-deprecating humour of the protagonist (played by Allen) serves as but one motif in a rich portrayal of a con-

temporary urban romantic relationship. *Annie Hall* won four Academy Awards, including awards for best picture and director. He also starred in the film version (1972) of his successful Broadway play *Play It Again, Sam* (1969).

Allen's subsequent films contain a paradoxical blend of comedy and philosophy and a juxtaposition of trivialities with major concerns. The bleakly serious drama *Interiors* (1978) was followed by the highly acclaimed seriocomedy *Manhattan* (1979). In such later films as *Zelig* (1983), *The Purple Rose of Cairo* (1985), *Hannah and Her Sisters* (1986), and *Crimes and Misdemeanors* (1989), Allen attempted with varying success to blend his vein of absurd humour with more realistic narratives, a wider range of character portrayals, and light but basically serious themes.

Through most of the 1990s he worked largely outside of the Hollywood system, producing low-budget films that attracted loyal fans, including *Husbands and Wives* (1992), *Bullets over Broadway* (1994), and *Sweet and Lowdown* (1999). In 1992 Allen found himself at the centre of a scandal when his longtime relationship with Farrow ended and it was revealed that he was having an affair with Farrow's adopted daughter, Soon-Yi Previn, whom he later married. Allen scored a modest hit in 2000 with the crime caper *Small Time Crooks*.

Allenby (of Megiddo and of Felixstowe), Edmund Henry Hynman Allenby, 1st Viscount (b. April 23, 1861, Brackenhurst, near Southwell, Nottinghamshire, Eng.—d. May 14, 1936, London), the last great British leader of mounted cavalry, who directed the Palestine campaign in World War I.

Educated at the Royal Military Academy, Sandhurst, Allenby joined the Inniskilling

Lord Allenby, portrait by Eric Henri Kennington; in the National Portrait Gallery, London

Courtesy of the National Portrait Gallery, London

Dragoons in 1882. He was inspector general of cavalry from 1910 to 1914, and upon the outbreak of World War I he took command of a series of cavalry divisions.

In June 1917 he took command of the Egyptian Expeditionary Force. The strength of his personality created a new spirit in his army, and he won a decisive victory over the Turks at Gaza (November 1917), which led to the capture of Jerusalem (Dec. 9, 1917). He won a decisive victory at Megiddo (Sept. 19, 1918), which, followed by his capture of Damascus and Aleppo, ended Ottoman power in Syria. As high commissioner for Egypt (1919–25) Allenby steered that country toward sovereignty in 1922.

He was created 1st Viscount Allenby of Megiddo and Felixstowe in October 1919.

Allende (Gossens), Salvador (b. July 26, 1908, Valparaíso, Chile—d. Sept. 11, 1973, Santiago), Chile's first Marxist president.

Allende, born into an upper-middle-class family, received his medical degree in 1932 from the University of Chile, where he was a

Marxist activist. He participated in the founding (1933) of Chile's Socialist Party. After election to the Chamber of Deputies in 1937, he served (1939-42) as minister of health in the liberal leftist coalition of President Pedro Aguirre Cerda. Allende won the first of his four elections to the Senate in 1945.

He ran for the presidency for the first time in 1952 but was temporarily expelled from the Socialist Party for accepting the support of the outlawed Communists; he placed last in a four-man race. He ran again in 1958—with Socialist backing, as well as the support of the then-legal Communists—and was a close second to the Conservative-Liberal candidate, Jorge Alessandri. Again with the same support he was decisively defeated (1964) by the Christian Democrat Eduardo Frei. For his successful 1970 campaign Allende ran as the candidate of Popular Unity, a bloc of Socialists, Communists, Radicals, and some dissident Christian Democrats, leading in a three-sided race with 36.3 percent of the vote. Because he lacked a popular majority, however, his election had to be confirmed by Congress, in which there was strong opposition from the right. Nevertheless, it was confirmed on Oct. 24, 1970, after he had guaranteed support to 10 libertarian constitutional amendments demanded by the Christian Democrats.

Inaugurated on Nov. 3, 1970, Allende began to restructure Chilean society along socialist lines while retaining the democratic form of government and respecting civil liberties and the due process of law. He expropriated the U.S.-owned copper companies in Chile without compensation, an act which set him seriously at odds with the U.S. government and weakened foreign investors' confidence in his government. His government also took steps to purchase several important privately owned mining and manufacturing sectors and to take over large agricultural estates for use by peasant cooperatives. In an attempt to redistribute incomes, he authorized large wage increases and froze prices. He also printed large amounts of unsupported currency to erase the fiscal deficit created by the government's purchase of basic industries. By 1972 Chile was suffering from stagnant production, decreased exports and private-sector investment, exhausted financial reserves, widespread strikes, rising inflation, food shortages, and domestic unrest. International lines of credit from the United States and western Europe had completely dried up. Allende's inability to control his own radical left-wing supporters further incurred the hostility of the middle class. In foreign affairs, he established relations with China and Cuba.

Allende retained the support of many workers and peasants; his electoral coalition won 44 percent of the vote in the March 1973 congressional elections. His government, however, was overthrown by a military coup on Sept. 11, 1973. Allende shot himself during a concerted military attack on the presidential palace on that day. His suicide was not publicly acknowledged until 1990, when his body was exhumed from an unmarked grave and given a formal, public burial in Santiago.

Allentown, city, seat (1812) of Lehigh county, eastern Pennsylvania, U.S. Situated on the Lehigh River, Allentown, with Bethlehem and Easton, forms an industrial complex. William Allen, mayor of Philadelphia and later chief justice of Pennsylvania, laid out the town (1762), naming it Northampton. It was incorporated as the borough of Northampton in 1811 and was later (1838) officially renamed Allentown for its founder.

Construction of a bridge (1812) across the Lehigh and opening of the Lehigh Canal (1829) brought new economic opportunities

to the town; an iron industry was started in 1847, a cement plant in 1850, and a rolling mill in 1860. Allentown's location amid rich mineral deposits (iron ore, zinc, limestone) and fertile farmland has enhanced its development as an industrial and market centre.

The city is the seat of five colleges—Muhlenberg (1848), Cedar Crest (1867), Allentown College of St. Francis de Sales (1965), Lehigh Community College (1966), United Wesleyan (1972)—and the Allentown campus of Pennsylvania State University (1912). The Liberty Bell Shrine contains a replica of the original bell, which was brought to Allentown during the American Revolution for safekeeping in the Zion Reformed Church. Herds of buffalo, deer, and elk roam the Trexler-Lehigh Game Preserve. Inc. city, 1867. Pop. (2000) city, 106,632; Allentown-Bethlehem-Easton MSA, 637,958.

Alleppey, town, southern Kerala state, southwestern India. It lies on a narrow land spit between the Arabian Sea and Vembanād Lake, south of Cochin. The town's port was opened to foreign trade by the British in the late 18th century to end the commercial supremacy of the Dutch trading post at Porakad, 10 miles (16 km) away. The town's economy is based largely on the coconut. Coconut oil is milled there, and coir ropes, mats, and carpets are manufactured and exported. Black pepper is also produced. The town lies on the main road between Cochin and Trivandrum. No railroad reaches it, but a network of canals connects it to Trichūr to the north and to Trivandrum to the south. The anchorage, situated about a mile offshore, is protected by a mudbank. Several colleges affiliated with the University of Kerala are located in Alleppey. Pop. (1991) town, 174,666; urban agglom. 264,969.

Allerdale, district, county of Cumbria, northwestern England, occupying an area of 486 square miles (1,259 square km) in the northwestern part of the county. It borders the Irish Sea on the west, Solway Firth on the northwest, and Scotland on the north. Except for its coastal plain on the west and northwest, Allerdale is a scenic mountain- and lake-filled valley district forming the northwestern part of the Lake District National Park in the Cumbrian Mountains. The two most populated centres of the district, Workington and Maryport, both on the western coast, have long been associated with the coalfield of Cumbria. Workington, the only deepwater port between Liverpool and Glasgow, has blast furnaces that reduce imported iron ore and has metallurgical industries that utilize locally mined anhydrite. Maryport exports footwear, chemicals, and plastics.

The fertile soils of the Solway coast northeast of these ports are used to grow oats and potatoes, except in the low-lying areas that are subject to tidal invasion. Dairy cattle are also raised along the Solway coast. The old stone-built parish of Keswick is a principal tourist centre of the Lake District. The prehistoric stone circles in the mountains and the Roman ruins and Viking graves nearer the seacoast are evidence of ancient settlement in the region. District meetings are held at Wigton. Pop. (1998 est.) 96,100.

allergen, substance that in some persons induces the hypersensitive state of allergy and stimulates the formation of reaginic antibodies. Allergens may be naturally occurring or of synthetic origin and include pollen, mold spores, dust, animal dander, insect debris, foods, blood serum, and drugs. Identification of allergens is made by studying both the site of symptoms (*e.g.*, inhalants such as molds, pollens, and dander usually affect the eyes, nose, and bronchi; cosmetics often affect the skin of the face and hands) and the time that symptoms appear (*e.g.*, seasonal allergy to pollen). *See also* antigen; reagin.

allergy, hypersensitive reaction by the body to foreign substances (antigens) that in similar amounts and circumstances are harmless within the bodies of other people.

A brief treatment of allergies follows. For full treatment, *see* MACROPAEDIA: Immunity.

Antigens that provoke an allergic reaction are called allergens. Typical allergens include pollens, drugs, lint, bacteria, foods, and dyes or chemicals. The immune system contains several mechanisms that normally protect the body against antigens. Prominent among these are the lymphocytes, cells that are specialized to react to specific antigens. There are two kinds of lymphocytes—B cells and T cells. B cells produce antibodies, which are proteins that bind to and destroy or neutralize antigens. T cells do not produce antibodies; instead, they bind directly to an antigen and stimulate an attack on it. Allergic reactions can have immediate or delayed effects, depending on whether the antigen triggers a response by B cells or T cells.

Allergic reactions with immediate effects are the result of antibody-antigen responses (*i.e.*, they are the products of B-cell stimulation). These can be divided into three basic types.

Type I reactions, which include hay fever, insect venom allergy, and asthma, involve the class of antibodies known as immunoglobulin E (IgE). IgE molecules are bound to mast cells, which are found in loose connective tissue. When enough antigen has bound with the IgE antibodies, the mast cells release granules of histamine and heparin and produce other agents such as the leukotrienes. These potent chemicals dilate blood vessels and constrict bronchial air passages. Histamine is responsible for the visible symptoms of an allergic attack, such as running nose, wheezing, and tissue swelling. A severe, often fatal, type I allergic reaction is known as anaphylactic shock (*see* anaphylaxis). The predisposition of a person to type I allergic reactions is genetically determined. The best protection against such allergies is avoidance of the offending substance. Antihistamine drugs are often used to give temporary relief. Another helpful measure is desensitization, in which increasing amounts of the antigen are injected over a period of time until the sufferer no longer experiences an allergic response.

Type II reactions result when antibodies react with antigens that are found on certain "target" cells. The antigens may be natural components of healthy cells, or they may be extrinsic components induced by drugs or infectious microbes. The resultant antigen-antibody complex activates the complement system, a series of potent enzymes that destroy the target cell.

Type III reactions result when a person who has been strongly sensitized to a particular antigen is subsequently exposed to that antigen. In a type III reaction, the antigen-antibody complex becomes deposited on the walls of the small blood vessels. The complex then triggers the complement system, which produces inflammation and vascular damage. Unlike type I reactions, type II and type III reactions are not dependent on a genetic predisposition. Avoidance of known allergens is the best protection against such reactions.

Delayed, or type IV, allergic reactions are caused by the actions of T cells, which take longer to accumulate at the site where the antigen is present than do B-cell antibodies. The allergic responses appear 12 to 24 hours or more after exposure to an appropriate antigen. A common delayed allergic reaction is contact dermatitis, a skin disorder. The rejection of transplanted organs is also mediated by T cells and thus may be considered a delayed allergic response.

Allerød, interstadial, or transient, period of glacial retreat that occurred at the close of the Würm Glacial Stage in Alpine Europe. Radio-

carbon dating techniques indicate that Allerød time began about 12,000 years ago. The Allerød was followed by a period of renewed cold and glacial advance. During the Allerød, the glacial ice front was situated in southern Finland and the central portions of Sweden. Conditions had moderated sufficiently to allow much of the once-barren tundra regions to become forested again. Tundra conditions still persisted, however, in regions near the still-extant ice sheets. In regions south of the ice, forests dominated by pine and spruce or birch existed in different regions.

Although cooler than modern climatic regimes, Allerød temperatures were significantly warmer than those that had prevailed during the periods of maximum glaciation. During the Allerød in Britain, glaciated regions were restricted to the Highlands of Scotland. Sea levels were higher during the Allerød than during colder times and approached modern sea levels. They were low enough, however, to keep the Strait of Dover and a large area of the North Sea bottom above water.

alley cat: *see* domestic shorthair.

Alleyn, Edward (b. Sept. 1, 1566, London—d. Nov. 25, 1626, London), one of the greatest actors of the Elizabethan stage and founder of Dulwich College, London. Rivalled only by Richard Burbage, Alleyn won the outspoken

Alleyn, oil painting by an unknown artist

By courtesy of the governors of Dulwich College Picture Gallery, London

admiration of such authors as Ben Jonson and Thomas Nashe for his interpretations of Christopher Marlowe's *Tamburlaine*, *Doctor Faustus*, and *The Jew of Malta* and of Robert Greene's *Orlando Furioso*.

After his marriage (1592) to Joan Woodward, stepdaughter of the theatrical manager Philip Henslowe, he became part owner in Henslowe's ventures (which included bear-baiting and bullbaiting as well as theatrical enterprises) and eventually sole proprietor of several playhouses and other properties in London. Among these were the Rose Theatre at Bankside, the Paris Garden, and the Fortune Theatre in St. Luke's—the last occupied by the Admiral's Men, with which Alleyn was associated as the leading actor and manager off and on from c. 1587. In 1619 Alleyn founded the College of God's Gift at Dulwich, later reorganized as Dulwich College. In 1623 his wife died, and he married Constance, daughter of the poet John Donne.

Allgemeine Enzyklopädie der Wissenschaften und Künste (German: "Universal Encyclopaedia of Sciences and Arts"), monumental uncompleted German encyclopaedia of which 167 volumes were published from 1818 to 1889. Founded by a German bibliographer, Johann Samuel Ersch, who began work on it in 1813, the *Allgemeine Enzyklopädie der Wissenschaften und Künste* is noteworthy for containing the longest known encyclopaedia article—the article about Greece, covering 3,668 pages in volumes 80–87. The signed articles of the work were written by leading German scholars of the 19th century.

Allgemeine Zeitung (German: "General Newspaper"), greatest German newspaper in the 19th century, founded at Tübingen in 1798 by Johann Friedrich Cotta, later Freiherr (baron) von Cottendorf. Censorship and other pressures forced it to move successively to Stuttgart, Ulm, Augsburg, and Munich. The name has been carried on in a sense by the *Frankfurter Allgemeine* and the *Westdeutsche Allgemeine* of Essen; together with the *Süddeutsche Zeitung* of Munich, all leading newspapers of Germany.

Allgemeines Landrecht: *see* Prussian Civil Code.

Allgood, Sara (b. Oct. 31, 1883, Dublin—d. Sept. 13, 1950, Woodland Hills, Calif., U.S.), Irish character actress who performed in the original Sean O'Casey plays produced at Dublin's Abbey Theatre and in many American motion pictures of the 1940s. Her early instructors included Frank and W.G. Fay, W.B. Yeats, and John Millington Synge.

In 1903 Allgood joined the Fays' Irish National Theatre Society as Princess Buan in *The King's Threshold*. In 1904 she played Cathleen in *Riders to the Sea* and late that year made her first appearances in Dublin with the Abbey Theatre Company. During the next 10 years with the Abbey, she also played Mrs. Delane in *Hyacinth Halvey* and Widow Quin in *The Playboy of the Western World*. She joined the Liverpool Repertory Company in 1914, later played with other companies at Manchester and Stratford, and appeared in several plays with her younger sister, Maire O'Neill. She toured Australia in 1916 in the title role of *Peg O' My Heart* and appeared as Mrs. Geogheghan in *The White-Headed Boy* at the Abbey Theatre in 1920. For the Abbey Players, she created the original Juno Boyle in *Juno and the Paycock* (1924) and the first Bessie Burgess in *The Plough and the Stars* (1926). The former role was repeated in New York City in 1940 and became the actress's swan song to the legitimate stage. She settled in the United States and thereafter worked only in motion pictures.

Allgood's film debut took place in the first British talkie, *Blackmail* (1929), and her other English-made films include *The Passing of the Third Floor Back* (1935), *Storm in a Teacup* (1937), and *Kathleen* (1938). Her American films include *How Green was My Valley* (1941), *Roxie Hart* (1942), *Between Two Worlds* (1944), *Jane Eyre* (1944), *The Lodger* (1944), *The Spiral Staircase* (1946), *Mourning Becomes Electra* (1947), *My Wild Irish Rose* (1947), and *Cheaper by the Dozen* (1950).

Alliaceae, family of flowering plants in the order Liliales, with about 30 genera and more than 670 species, distributed throughout most regions of the world, except for the tropics,

Wild garlic (*Allium ursinum*)

A to Z Botanical Collection—EB Inc

Australia, and New Zealand. Members of the family have corms, bulbs, or underground stems; most have long, thin leaves and clusters of varying numbers of flowers. The genus *Allium* contains the common onion (*A. cepa*), wild onion (*A. cernuum*), garlic (*A. sativum*), wild garlic (*A. ursinum*), leek (*A. porrum*), chives (*A. schoenoprasum*), and shallot (*A. ascallonicum*). Many other onion- or garlic-scented species are cultivated as ornamental border plants, such as *A. moly*, *A. carinatum*, and *A. pulchellum* of Europe, as well as *A. stellatum* and *A. textile* of North America.

Plants of the genus *Agapanthus* are fast-growing ornamental pot plants with tuberous roots and tall clusters of blue flowers. African lily, or lily of the Nile (*Agapanthus africanus*), has many varieties, some with white or purple flowers and others with patterned leaves. Similar plants of the genus *Tulbaghia* also are popular ornamentals. *Tulbaghia violacea* has a thick stem, garlic-scented leaves, and urn-shaped purple flowers. Ornamental species of the genus *Brodiaea*, known as triplet lilies, have narrow, grasslike leaves and funnel-shaped flowers, usually purple or blue. Spring starflower (*B. uniflora*) is the most commonly cultivated species.

Alliance, city, Stark county, northeastern Ohio, U.S., on the Mahoning River, 21 mi (34 km) northeast of Canton. In 1854 the villages of Williamsport, Freedom, and Liberty were incorporated as the village of Alliance, so named for the junction and crossing there of the former New York Central and Pennsylvania railroads. The village of Mount Union (settled in 1833) became a part of Alliance in 1854. Now highly industrialized, the city manufactures heavy mill machinery, traveling cranes, bricks and tiles, abrasives, and a variety of steel, machine, and metal products. It is the seat of Mount Union College (1846). Inc. city, 1889. Pop. (1990) 23,376.

alliance, in international relations, a union for joint action of various powers or states, such as the alliance of the European powers and the United States against Germany and its allies during World War II, or of the North Atlantic Treaty Organization (NATO) states against the Soviet Union and its allies.

Alliances in modern times require a joint effort far more integrated than was called for by alliances in earlier times. Thus, for example, in the coalitions of World War II, combined agencies for military and economic planning were a common and conspicuous feature. Even in less tightly knit alliances, such as NATO, great importance is attached to close and cooperative action, both military and political, particularly in the context of the 20th-century strategy of nuclear deterrence.

Alliance for Progress, international economic development program established by the United States and 22 Latin American countries in the Charter of Punta del Este (Uruguay) in August 1961. Objectives stated in the charter centred on the maintenance of democratic government and the achievement of economic and social development; specific goals included a sustained growth in per capita income, more equitable distribution of income, accelerated development in industry and agriculture, agrarian reform, improvement of health and welfare, stabilization of export prices, and domestic price stability.

At the start of the program, it was estimated that \$20,000,000,000 of external capital would be needed during the first 10 years; about half was to be obtained from the United States and the rest from international lending agencies and from private sources. The Inter-American Committee on the Alliance for Progress (CIAP) was created in 1963 to serve as the coordinat-

ing agent between the international financial community and the countries involved and to review the economic policies and plans of each country to determine the need for and availability of external finance.

Although the program could show some newly built schools, hospitals, and other physical plants, it failed in the judgment of most observers. Massive land reform was not achieved; population more than kept pace with gains in health and welfare. U.S. aid decreased over the years, and political tensions between the United States and Latin America increased.

Allied Powers, also called ALLIES, those nations allied in opposition to the Central Powers (Germany, Austria-Hungary, and Turkey) in World War I or to the Axis Powers (Germany, Italy, and Japan) in World War II.

The major Allied Powers in World War I were the British Empire, France, and the Russian Empire, formally linked by the Treaty of London of Sept. 5, 1914; other nations that had been, or came to be, allied by treaty to one or more of these powers were also called Allies: Portugal and Japan by treaty with Britain; Italy by the Treaty of London of April 26, 1915, with all three powers. Other nations—including the United States after its entry on April 6, 1917—that were arrayed against the Central Powers were called "Associated Powers," not Allied Powers; U.S. President Woodrow Wilson emphasized this distinction to preserve America's free hand. The Treaty of Versailles concluding the war listed 27 "Allied and Associated Powers" (Belgium, Bolivia, Brazil, the British Empire, China, Cuba, Czechoslovakia, Ecuador, France, Greece, Guatemala, Haiti, the Hejaz, Honduras, Italy, Japan, Liberia, Nicaragua, Panama, Peru, Poland, Portugal, Romania, Serb-Croat-Slovene State, Siam, the United States, and Uruguay).

In World War II the chief Allied Powers were Great Britain, France (except during the German occupation, 1940–44), the Soviet Union (after its entry in June 1941), the United States (after its entry on Dec. 8–11, 1941), and China. More generally the Allies included all the wartime members of the United Nations, the signatories to the Declaration of the United Nations. The original signers, of Jan. 1, 1942, were Australia, Belgium, Canada, China, Costa Rica, Cuba, Czechoslovakia, Dominican Republic, Great Britain, Greece, Guatemala, Haiti, Honduras, India, Luxembourg, The Netherlands, New Zealand, Nicaragua, Norway, Panama, Poland, Salvador, South Africa, the Soviet Union, the United States, and Yugoslavia; subsequent wartime signers were the Philippines, Mexico, Ethiopia, Iraq, Free French, and Free Danes.

AlliedSignal Inc., originally (until 1958) ALLIED CHEMICAL & DYE CORPORATION, former American corporation that became a leading manufacturer of aerospace systems and components before merging with Honeywell (*q.v.*) in 1999.

The corporation was formed in 1920 through the consolidation of several chemical manufacturers: the Barrett Company (founded 1903), supplying coal-tar chemicals and roofing; General Chemical Company (founded 1899), specializing in industrial acids; National Aniline & Chemical Company (founded 1917), producing dyes; Semet-Solvay Company (founded 1894), manufacturing coke and its by-products; and Solvay Process Company (founded 1881), producing alkalis and nitrogen materials. In the 1940s these companies were reorganized as divisions of Allied Chemical. Further reorganizations and acquisitions of companies and plants during the 1950s, '60s, and '70s transformed Allied into a conglomerate. In 1982 the company acquired Bendix Corporation, a manufacturer of auto-

motive and aerospace equipment. Allied merged in 1985 with Signal Companies, a major aerospace and engineering firm, to form Allied-Signal Inc., in a transaction representing the largest industrial merger up to that time. In 1986 Allied-Signal concentrated on its growing aerospace electronics and automotive operations. In 1999, the renamed AlliedSignal acquired the shares of Honeywell Inc. but dropped the AlliedSignal name in favour of Honeywell International Inc.

Allier, département, Auvergne région, central France, on the northern rim of the Massif Central. Formed from the old province of Bourbonnais, it has an area of 2,834 square miles (7,340 square km). Allier is traversed from south to north by the Allier River. The *département* is bounded on the northeast by the Loire River, and the Cher River flows parallel to the Allier across the *département's* western portion. The reclamation of heathland, known as the Sologne Bourbonnaise, has expanded the raising of livestock in the area. The Limagne Bourbonnaise, in the south-central part of the *département*, is fertile and well cultivated. The heights of the Forez region in the southeast, reaching 3,383 feet (1,031 m), have severe winters.

The castle at Bourbon-l'Archambault was the seat of the first Bourbon lords. There are other noteworthy medieval buildings at Moulins, Souvigny (Cluniac priory), Saint-Menoux, Ébreuil, Gannat, Veauce and Ygrande (Romanesque churches), Huriel, and Saint-Pourçain-sur-Sioule.

East of the Cher River are scattered outcrops of coal, but the exploitation of the coal basin is declining as industry locates in Montluçon (tires and machinery). Vichy in the south, on the Allier River, is the best-known spa in France. Allier's *arrondissements* centre on Moulins (the capital), Montluçon, and Lapolis. Pop. (2003 est.) 342,307.

Allier River, Latin ELAVER, river, central France, that joins the Loire River 4 miles (6 km) west of Nevers after a course of 255 miles (410 km). Rising in Lozère *département*, it races through deep gorges along structural lines of weakness between the Margeride and Velay mountains. Traversing the basins of Langeac and Brioude, it receives torrents from the mountains of Dore and Puy-de-Dôme and flows broad and shallow through the wheat country, the Grande Limagne, north of Clermont-Ferrand. It is joined by the Sioule above Moulins, the second largest town on its banks. Its drainage basin covers 5,573 square miles (14,434 square km).

Allies: see Allied Powers.

alligator (genus *Alligator*), either of two long-snouted, crocodylian reptiles usually placed with the South American caimans in the fam-

Alligator (*Alligator mississippiensis*)

P. Morris—Woodfin Camp and Associates

ily Alligatoridae. Alligators, like other crocodylians, are large, lizardlike animals with powerful tails that are used both in defense and in swimming. Their eyes, ears, and nostrils are placed on top of their long head and project slightly above the water when the reptiles float at the surface, as they often do. Alligators differ from crocodiles in having broader snouts; in crocodiles, moreover, the fourth tooth in each side of the lower jaw projects

outside the snout when the mouth is closed. Alligators are carnivorous and live along the edges of relatively large bodies of water, such as lakes, swamps, and rivers. They dig burrows in which they escape from danger and in which they hibernate during cold weather.

The Mississippi, or American, alligator (*Alligator mississippiensis*), the larger of the two species, is found in the southeastern United States. It is black with yellow banding when young and is generally brownish when adult. The maximum length is about 5.8 m (19 feet), but it more typically ranges from about 1.8 to 3.7 m (6 to 12 feet). The Mississippi alligator has been hunted for its hide, and its young have been sold in large numbers as pets. It disappeared from many areas where it was once abundant and was later given legal protection from hunters, until it made an excellent comeback and limited hunting seasons were again established. The adult alligator feeds mainly on fishes, small mammals, and birds but may sometimes take prey as large as deer or cattle. Members of both sexes hiss, and the males also give loud roars that carry over considerable distances. During the breeding season, the female builds a mound nest of mud and vegetation in which she buries about 20 to 70 hard-shelled eggs. She guards the eggs and may at this time be dangerous. Members of this species usually avoid humans.

The Chinese alligator (*A. sinensis*) is a much smaller, little-known reptile found in the Yangtze River region of China. It is similar to the larger form but attains a maximum length of about 1.5 m (5 feet) and is blackish with faint yellowish markings. It is considered endangered (and perhaps extinct) by the International Union for Conservation of Nature and Natural Resources (IUCN).

alligator apple, fruit tree of tropical America valued for its wood. See custard apple.

Alligator Rivers, three perennial rivers, northeastern Northern Territory, Australia, that empty into Van Diemen Gulf, an inlet of the Timor Sea. They were explored in 1818–20 by Captain Phillip Parker King, who named them in the belief that the crocodiles infesting their lower swampy, jungle-fringed reaches were alligators (actually, Australia has no alligators). The South Alligator rises in the hills near El Sherana, a mining base for uranium, and follows a northerly course for about 100 miles (160 km). The East Alligator rises in Arnhem Land and flows northwesterly for nearly 100 miles; the West Alligator (50 miles) generally parallels the course of the South Alligator. The region includes the Kakadu National Park.

Allingham, Margery in full MARGERY LOUISE ALLINGHAM (b. May 20, 1904, London, Eng.—d. June 30, 1966, Colchester, Essex), British detective-story writer of unusual subtlety, wit, and imaginative power, who created the bland, bespectacled, keen-witted Albert Campion, one of the most interesting of fictional detectives.

Campion's career was begun with a group of ingenious, popular thrillers: *The Crime at Black Dudley* (1928; U.S. title, *The Black Dudley Murder*), *Mystery Mile* (1929), *Police at the Funeral* (1931), and *Sweet Danger* (1933). A series of more tightly constructed intellectual problem stories, beginning with *Death of a Ghost* (1934) and including *Flowers for the Judge* (1936), *The Fashion in Shrouds* (1938), and *Traitor's Purse* (1941), gained Allingham critical esteem; and with *Coroner's Pidgin* (1945; U.S. title, *Pearls Before Swine*), *More Work for the Undertaker* (1949), *Tiger in the Smoke* (1952)—a novel that revealed her psychological insight and her power to create an atmosphere of pervasive, mindless evil—and *The China Governess* (1963), she made a valuable contribution to the development of the detective story as a serious literary genre.

Campion's career was continued in *Cargo of Eagles* (1968), left unfinished when Allingham died and completed by her husband. Philip Youngman Carter.

Allison, William B., in full WILLIAM BOYD ALLISON (b. March 2, 1829, Ashland, Ohio, U.S.—d. Aug. 4, 1908, Dubuque, Iowa), U.S. representative (1863–71) and senator (1873–1908) from Iowa, cosponsor of the Bland-Alli-

Allison
By courtesy of the Library of Congress, Washington, D.C.

son Act of 1878, which expanded U.S. Treasury purchase of silver bullion and restored the silver dollar as legal tender.

Allison practiced law in his hometown of Ashland, Ohio, and (from 1857) in Dubuque, Iowa. In the House of Representatives he was a partisan of railroad interests, but as a senator he helped to pass the Hepburn Act (1906), a railway rate-regulation bill, on behalf of President Theodore Roosevelt. Although identified with the silver-purchase act, which he cosponsored, he was more important as a member of the powerful House Ways and Means Committee and as chairman of the Senate Committee on Appropriations. With Nelson W. Aldrich, Orville H. Platt, and John C. Spooner, he made up "the Four" who dominated the Senate in the early 1900s. He twice (1888, 1896) was a contender for the Republican presidential nomination.

alliteration, in prosody, the repetition of consonant sounds at the beginning of words or stressed syllables. Sometimes the repetition of initial vowel sounds (head rhyme) is also referred to as alliteration. As a poetic device, it is often discussed with assonance and consonance. In languages (such as Chinese) that emphasize tonality, the use of alliteration is rare or absent.

Alliteration is found in many common phrases, such as "pretty as a picture" and "dead as a doornail," and is a common poetic device in almost all languages. In its simplest form, it reinforces one or two consonantal sounds, as in William Shakespeare's line:

When I do count the clock that tells the time
(Sonnet XII)

A more complex pattern of alliteration is created when consonants both at the beginning of words and at the beginning of stressed syllables within words are repeated, as in Percy Bysshe Shelley's line:

The City's voice itself is soft like Solitude's
(“Stanzas Written in Dejection Near Naples”)

Though alliteration is now a subsidiary embellishment in both prose and poetry, it was a formal structural principle in ancient Germanic verse. See alliterative verse. Compare assonance; consonance.

alliterative verse, early verse of the Germanic languages in which alliteration, the repetition of consonant sounds at the beginning of words or stressed syllables, is a basic structural principle rather than an occasional embellishment. Although alliteration is a common device in almost all poetry, the only Indo-

European languages that used it as a governing principle, along with strict rules of accent and quantity, are Old Norse, Old English, Old Saxon, Old Low German, and Old High German. The Germanic alliterative line consists of two hemistichs (half lines) separated by a caesura (pause). There are one or two alliterating letters in the first half line preceding the medial caesura; these also alliterate with the first stressed syllable in the second half line. Alliteration falls on accented syllables; unaccented syllables are not effective, even if they begin with the alliterating letter.

The introduction of rhyme, derived from medieval Latin hymns, contributed to the decline of alliterative verse. In Low German, pure alliterative verse is not known to have survived after 900; and, in Old High German, rhymed verse was by that time already replacing it. In England, alliteration as a strict structural principle is not found after 1066 (the date of the Norman-French conquest of Britain), except in the western part of the country. Although alliteration was still very important, the alliterative line became freer: the second half line often contained more than one alliterating word, and other formalistic restrictions were gradually disregarded. The early 13th-century poetry of Layamon and later poems such as *Piers Plowman*, *Sir Gawayne and the Grene Knight*, and *The Pearl* use end rhyme extensively. Sometimes all the verses rhyme; sometimes the succession of alliterative verses is broken by rhymed verses grouped at roughly regular intervals. The last alliterative poem in English is usually held to be "Scottish Fielde," which deals with the Battle of Flodden (1513).

Later Norse poets (after 900) also combined many forms of rhyme and assonance with alliteration in a variety of stanzaic forms. After 1000, Old Norse alliterative verse became practically confined to the Icelanders, among whom it continues to exist.

In Celtic poetry, alliteration was from the earliest times an important, but subordinate, principle. In Welsh poetry it gave rise to the *cynghanedd* (*q.v.*), an intricate bardic verse.

Allobroges, ancient Celtic tribe living in the northeast of Gallia Narbonensis (*i.e.*, Narbonne Gaul, in the part of southeastern France bounded by the Rhône and Isère rivers) and in the area around Geneva. The Allobroges were first mentioned in history when Hannibal passed through their territory in 218 BC. Later, they were attacked by the Romans and finally conquered (121 BC) at the junction of the Rhône and Isère and were thereafter incorporated in Transalpine Gaul.

allocation of resources: see resources, allocation of.

allodium, land freely held, without obligation of service to any overlord. Allodial land tenure was of particular significance in Europe during the Middle Ages, when most land was held by feudal tenure.

The anarchy that ensued in France after the decline of the Carolingian monarchy at the end of the 9th century allowed much land to be seized and held free, although a large part of it was eventually brought into a feudal relationship in which the holder owed certain services to his lord. By the 12th and 13th centuries, the only appreciable amount of allodial land remaining was limited to peasant holdings in the southwest. In Germany large allodial estates held by nobles continued to exist, particularly in Saxony. In England there was a considerable amount of allodial land before the Norman Conquest (1066), but it disappeared under the new rulers. Allodial land, though free of limitations from above, was not free of restrictions from below if the holder chose to have feudal tenants. He would then owe certain obligations to them, primarily in terms of protection, and could not be considered in absolute control of his holdings.

With the decline of feudalism in France, land that had been under the jurisdiction of a lord came to be under the jurisdiction of the king, who collected certain fees upon its sale or transfer. Following the French Revolution (1789) all land became allodial. In England no land is referred to as allodial, but an estate in fee simple corresponds in practice to absolute ownership.

allophone, one of the phonetically distinct variants of a phoneme (*q.v.*). The occurrence of one allophone rather than another is usually determined by its position in the word (initial, final, medial, etc.) or by its phonetic environment. Speakers of a language often have difficulty in hearing the phonetic differences between allophones of the same phoneme, because these differences do not serve to distinguish one word from another. In English the *t* sounds in the words "hit," "tip," and "little" are allophones; phonemically they are considered to be the same sound although they are different phonetically in terms of aspiration, voicing, and point of articulation. In Japanese and some dialects of Chinese, the sounds *f* and *h* are allophones.

allopurinol, organic compound used in treating gout. Allopurinol interferes with the body's formation of uric acid, a substance present in abnormally large amounts in the blood of persons suffering from gout. In cases of gout, the uric acid forms solid deposits in the joints, the kidneys, and other tissues.

Allopurinol is mainly used to treat the severe, chronic forms of gout. Treatment of gout with allopurinol ordinarily is expected to be continued for many years, if not indefinitely. The drug fosters the resorption of solid deposits in the joints, thus improving joint function. Allopurinol is preferred over such uricosuric drugs as probenecid or sulfinpyrazone, because it decreases the amount of uric acid excreted in the urine and thus discourages the formation of uric-acid kidney stones in gout patients. Compare uricosuric.

Allosaurus, formerly ANTRODEMUS, genus of large carnivorous dinosaurs found as fossils in Late Jurassic to Early Cretaceous rocks of North America, Africa, and Australia (the Jurassic Period preceded the Cretaceous Period and ended 144 million years ago). *Allosaurus* weighed 2 tons and grew to 10.4 m (34 feet) in length, half of which consisted of a well-developed tail that probably functioned as a counterbalance for the body. *Allosaurus*, a biped, had very strong hind limbs and a massive pelvis with strong anteriorly and posteriorly directed projections. The forelimbs, much smaller than the hind limbs and probably used for grasping, had three fingers ending in sharp claws. The skull was very large in relation to the compact body and was lightened by the presence of several large openings. The powerful jaws had large pointed teeth and were very flexible, allowing the animal to take large bites out of its prey. It is likely that *Allosaurus* preyed upon the medium-sized dinosaurs, especially the ornithomimid forms and their relatives. It is possible that *Allosaurus* was also a scavenger, feeding upon carcasses of dead or dying animals. It may have hunted in groups.

allosteric control, in enzymology, inhibition or activation of an enzyme by a small regulatory molecule that interacts at a site (allosteric site) other than the active site (at which catalytic activity occurs). The interaction changes the shape of the enzyme so as to affect the formation at the active site of the usual complex between the enzyme and its substrate (the compound upon which it acts to form a product). As a result, the ability of the enzyme to catalyze a reaction is modified. This is the

basis of the so-called induced-fit theory, which states that the binding of a substrate or some other molecule to an enzyme causes a change in the shape of the enzyme so as to enhance or inhibit its activity.

The regulatory molecule may be a product of a synthetic pathway and inhibit an enzyme in that pathway (see feedback inhibition), thereby preventing the further formation of itself. Other molecules act as activators; *i.e.*, they interact with an enzyme so as to enhance the binding of the substrate to the enzyme, thus enhancing catalytic activity. The enzyme adenyl cyclase, itself activated by the hormone adrenaline (epinephrine), which is released when a mammal requires energy, catalyzes a reaction that results in the formation of the compound cyclic adenosine monophosphate (cyclic AMP). Cyclic AMP, in turn, activates enzymes that metabolize carbohydrates for energy production. A combination of allosteric activation and inhibition thus provides a way by which the cell can rapidly regulate needed substances.

allotropy, the existence of a chemical element in two or more forms, which may differ in the arrangement of atoms in crystalline solids or in the occurrence of molecules that contain different numbers of atoms. The existence of different crystalline forms of an element is the same phenomenon that in the case of compounds is called polymorphism. Allotropes may be monotropic, in which case one of the forms is the most stable under all conditions, or enantiotropic, in which case different forms are stable under different conditions and undergo reversible transitions from one to another at characteristic temperatures and pressures.

Elements exhibiting allotropy include tin, carbon, sulfur, phosphorus, and oxygen. Tin and sulfur are enantiotropic: the former exists in a gray form, stable below 13.2° C, and a white form, stable at higher temperatures; sulfur forms rhombic crystals, stable below 95.5° C, and monoclinic crystals, stable between 95.5° C and the melting point (119° C). Carbon, phosphorus, and oxygen are monotropic; graphite is more stable than diamond, red phosphorus is more stable than white, and diatomic oxygen, having the formula O₂, is more stable than triatomic oxygen (ozone, O₃) under all ordinary conditions.

Allouez, Claude-Jean (b. June 6, 1622, Saint-Didier, Fr.—d. Aug. 27/28, 1689, near Ft. St. Joseph, New France), Jesuit missionary to New France who has been called the founder of Catholicism in the West.

Allouez entered the Society of Jesus at Toulouse, was ordained priest in 1655, and sailed for Quebec in 1658. He was stationed at settlements along the St. Lawrence River until his appointment (1663) as vicar general of the Northwest. He travelled extensively through that territory, preaching to the Indians and establishing missions—chiefly in present-day Wisconsin, including Chequamegon Bay and Green Bay. His own accounts of his activities are frequently quoted in *The Jesuit Relations*, edited by R.G. Thwaites. Allouez was a predecessor and later a colleague of Jacques Marquette, for whom he wrote a book of prayers. His last years were spent mostly among the Miamis of the St. Joseph River in modern southwestern Michigan.

Allouez Bay (Lake Superior, U.S.): see Superior Bay.

Alloway, southern suburb of the town of Ayr, Kyle and Carrick district, Strathclyde region, Scotland, famous as the birthplace, in 1759, of Scotland's national poet, Robert Burns. There is a museum alongside the thatched cottage where he was born and a memorial in the

form of a Grecian temple, built in 1820. Brig o' Doon, immortalized in Burns's poem "Tam o' Shanter," is nearby.

alloy, metallic substance composed of two or more elements, as either a compound or a solution. The components of alloys are ordinarily themselves metals, though carbon, a nonmetal, is an essential constituent of steel.

Alloys are usually produced by melting the mixture of ingredients. The value of alloys was discovered in very ancient times; brass (copper and zinc) and bronze (copper and tin) were especially important. Today, the most important are the alloy steels, broadly defined as steels containing significant amounts of elements other than iron and carbon. The principal alloying elements for steel are chromium, nickel, manganese, molybdenum, silicon, tungsten, vanadium, and boron. Alloy steels have a wide range of special properties, such as hardness, toughness, corrosion resistance, magnetizability, and ductility. Nonferrous alloys, mainly copper-nickel, bronze, and aluminum alloys, are much used in coinage. The distinction between an alloying metal and an impurity is sometimes subtle; in aluminum, for example, silicon may be considered an impurity or a valuable component, depending on the application, because silicon adds strength though it reduces corrosion resistance.

The term fusible metals, or fusible alloys, denotes a group of alloys that have melting points below that of tin (232° C, 449° F). Most of these substances are mixtures of metals that by themselves have low melting points, such as tin, bismuth, and lead. Fusible alloys are used as solder, in safety sprinklers that automatically spray out water when the heat of a fire melts the alloy, and in fuses for interrupting an electrical circuit when the current becomes excessive.

Many fusible alloys are formulated to melt at 90–100° C (194–212° F); for example, Darcet's alloy (50 parts bismuth, 25 lead, 25 tin) melts at 98° C. By replacing half the tin in Darcet's alloy with cadmium, the alloy Wood's metal, which melts at 70° C, is obtained. See also amalgam; ferroalloy; intermetallic compound.

Allport, Gordon W(illard) (b. Nov. 11, 1897, Montezuma, Ind., U.S.—d. Oct. 9, 1967, Cambridge, Mass., U.S. psychologist and educator who developed an original theory of personality.

Allport

By courtesy of Harvard University Archives

Appointed a social science instructor at Harvard University in 1924, he became professor of psychology six years later and, in the last year of his life, professor of social ethics. He consistently related his approach to the study of personality to his social interests and was one of a growing number of psychologists who sought to introduce the leavening influence of humanism into psychology. His important introductory work on the theory of personality was *Personality: A Psychological Interpretation* (1937).

Allport is best known for the theory that

although adult motives develop from infantile drives, they become independent of them. His approach favoured emphasis on the problems of the adult personality rather than on those of infantile emotions and experiences. In *Becoming* (1955) he stressed the importance of self and the uniqueness of adult personality. The self, he contended, is an identifiable organization within each individual and accounts for the unity of personality, higher motives, and continuity of personal memories. He also made important contributions to the analysis of prejudice in *The Nature of Prejudice* (1954). His last important work was *Pattern and Growth in Personality* (1961).

allspice, tropical evergreen tree (*Pimenta dioica*, formerly *P. officinalis*) of the myrtle family (Myrtaceae), native to the West Indies and Central America and valued for its berries, the source of a highly aromatic spice. Allspice was so named because the flavour of the dried berry resembles a combination of cloves, cinnamon, and nutmeg. It is widely used in baking and is usually present in mincemeat and mixed pickling spice. Early Spanish explorers, mistaking it for a type of pepper, called it

Allspice (*Pimenta dioica*)

J.E. Cruise

pimenta, hence its botanical name and such terms as pimento and Jamaica pepper. The first record of its import to Europe is from 1601.

The allspice tree attains a height of about 9 metres (30 feet). The fruits are picked before they are fully ripe and then dried in the sun. During drying the berries turn from green to a dull reddish brown. The nearly globular fruit, about 5 millimetres (0.2 inch) in diameter, contains two kidney-shaped, dark-brown seeds. Its flavour is aromatic and pungent. The essential oil content is about 4½ percent for Jamaica allspice and about 2½ percent for that of Central America; its principal component is eugenol.

The name allspice is applied to several other aromatic shrubs as well, especially to one of the sweet shrubs, the Carolina allspice (*Calycanthus floridus*), a handsome flowering shrub native to the southeastern United States and often cultivated in England. Other allspices include: the Japanese allspice (*Chimonanthus praecox*), native to eastern Asia and planted as an ornamental in England and the United States; the wild allspice, or spicebush (*Lindera benzoin*), a shrub of eastern North America, with aromatic berries, reputed to have been used as a substitute for true allspice.

Allston, Robert (Francis Withers) (b. April 21, 1801, All Saints Parish, S.C., U.S.—d. April 7, 1864, Georgetown, S.C.), rice planter and governor of South Carolina whose papers, *South Carolina Rice Plantation*, provide important agricultural, political, and social information about the pre-Civil War South. By scientifically draining and reclaiming swamps in his state, he developed one of the last great rice plantations in the Atlantic coast lowlands.

He was also the author of two authoritative and influential works on crop raising. Allston became president of the South Carolina

Robert Allston, detail of an oil painting by George Whiting Flagg, 1850s; in a private collection

By courtesy of William F. Allston

state senate (1847–56) and served as governor (1856–58).

Allston, Washington (b. Nov. 5, 1779, Allston plantation, Brook Green Domain on Waccamaw River, S.C., U.S.—d. July 9, 1843, Cambridgeport, Mass.), painter and author, commonly held to be the first important American Romantic painter. Allston is known for his experiments with dramatic subject matter and his use of light and atmospheric colour. Although his production was small, it shaped future American landscape painting by its dramatic portrayals of mood. Allston's work anticipated that of a line of American visionary painters including Albert Pinkham Ryder and Ralph Blakelock.

Allston graduated from Harvard University in 1800. He studied in London at the Royal Academy and visited the great museums of Paris (1803–04) and Italy (1804–08). During this period he became friendly with the writers Samuel Taylor Coleridge and Washington Irving. Allston spent the years from 1808 to 1811 in Boston. He then spent seven productive years in London and returned to Boston in 1818, finally settling in Cambridgeport, Mass., in 1830.

"Moonlit Landscape," oil on canvas by Washington Allston, 1819; in the Museum of Fine Arts, Boston

By courtesy of the Museum of Fine Arts Boston gift of William Sturgis Bigelow

Before his final return to the United States, Allston's art was dramatic and large in scale. He delighted in the supernatural; this taste is evident, for example, in "Belshazzar's Feast" (1817–43). His dramatic landscapes "The Deluge" (1804) and "Elijah in the Desert" (1818) are among the first important achievements of American landscape painting.

After his return to Boston in 1818 Allston's art became quieter, striking a new note of reverie and fantasy. "Moonlit Landscape" (1819) and "The Flight of Florimel" (1819) are the chief works of the period before he became preoccupied with "Belshazzar's Feast," which he had brought unfinished from Lon-

don. He worked on this from 1820 to 1828 and from 1839 until his death.

Allston was also a writer; his poems, *The Sylphs of the Seasons with Other Poems* (1813), and a Gothic novel, *Monaldi* (1841), were popular in his day. His theory of art was posthumously published as *Lectures on Art, and Poems* (1850).

Allucingoli, Ubaldo (pope): see Lucius III.

alluvial fan, unconsolidated sedimentary deposit that accumulates at the mouth of a mountain canyon because of a cessation of sediment transport by the issuing stream. The deposits, which are generally fan-shaped in plan view, can develop under a wide range of climatic conditions and have been studied in the Canadian Arctic, Swedish Lapland, Japan, the Alps, the Himalayas, and other areas. They tend to be larger and more prominent in arid and semiarid regions, however, and generally are regarded as characteristic desert landforms. This is particularly true in the basin-and-range type of areas of parts of Iran, Afghanistan, Pakistan, the western United States, Chile and Peru, Sinai and western Arabia, and Central Asia, where the basic landscape configuration consists of mountains set against adjacent basins.

A brief treatment of alluvial fans follows. For full treatment, see MACROPAEDIA: Rivers.

Alluvial fans are of practical and economic importance to man, particularly in arid and semiarid areas where they may be the principal groundwater source for irrigation farming and the sustenance of life. In some instances, entire cities, such as Los Angeles, have been built on alluvial fans.

Alluvial fans border the mountain fronts with the apex of each fan just within a canyon mouth that serves as the outlet for a mountain drainage system. Sediment from erosion within the mountains is moved by these drainage systems to the adjacent basin; in arid regions this occurs mainly during relatively infrequent flash floods that may involve mudflows. The fans, the main sites of deposition, are therefore an intrinsic part of an erosional-depositional system in which mountains tend

slowly to wear away and basins to fill with sediment through geologic time.

Since the rivers that deposit alluvial fans tend to be fast-flowing, the first material to be laid down is usually coarse. However, fans consist of a wide range of sediment sizes and a high degree of sorting from apex to base. The initial formation of a fan is often furthered by the infiltration of surface water into the early deposit of coarse debris. This infiltration encourages the deposition of finer material. Usually the coarser sedimentary fraction forms towards the apex, with fine sands and silts toward the base. In addition, the braided distributary channels also perform some sort-

ing, laying shallow sheets of sand and silt over the surface of the fan, while coarser sands and gravels are laid down in the main channels where water tends to flow more quickly.

Alluvial fans in desert or semiarid areas may act as groundwater reservoirs when stream water infiltrates the deposit and gradually percolates downward toward the base. If the water becomes trapped between impermeable layers within the fan, it may be tapped by wells along the base, and these may exhibit artesian flow as the groundwater builds up pressure within the fan. The use of desert fans as permanent sources of water is limited, however, because periodic rainfall provides only a very slow rate of recharge.

An alluvial fan can be large and may occupy a wide area, ranging from only a few metres in radius at its base to more than 150 km (95 miles). When a number of rivers discharge onto a plain, their fans may combine to create a piedmont alluvial fan.

Many fans in humid areas are actually fossil features created during earlier periods of intense erosion and deposition. The Plateau de Lannemezan on the northern side of the Pyrenees in France, for example, is a large piedmont alluvial fan that is still being built up by the tributaries of the Garonne and Adour rivers. This fan, though, is much too large to have been constructed by present-day rivers. It was formed during the Late Cenozoic Period and is made up of coarse Pliocene gravels derived from the Pyrenees.

alluvial plain: see floodplain.

alluvium, material deposited by rivers. It is usually most extensively developed in the lower part of the course of a river, forming floodplains and deltas, but may be deposited at any point where the river overflows its banks or where the velocity of a river is checked—for example, where it runs into a lake.

Alluvium consists of silt, sand, clay, and gravel and often contains a good deal of organic matter. It therefore yields very fertile soils such as those of the deltas of the Mississippi, the Nile, the Ganges and Brahmaputra, and the Huang rivers. In some regions alluvial deposits contain gold, platinum, or gemstones and the greater part of the world's supply of tin ore (cassiterite).

allyott (plant): see jute.

Alma, city, seat of Lac-Saint-Jean-Est regional county (*municipalité régionale de comté*), Saguenay-Lac-Saint-Jean region, south-central Quebec province, Canada, on Alma Island and both banks of the Saguenay River, an outlet of Lac-Saint-Jean (Lake St. John) 140 miles (230 km) north of Quebec city.

The city was mainly an agricultural community until after 1923, when the large Île-Maligne hydroelectric power project was developed. Alma's economy now largely depends on aluminum and paper processing and granite quarrying.

Founded in 1867 as Saint-Joseph-d'Alma, the settlement was chartered as a village in 1917 and as a town in 1924. In 1954 its name was shortened to Alma. It absorbed adjacent Naudville, Riverbend, and Isle-Maligne in 1962. In 1976 a new city of Alma was created from the amalgamation of the old city of Alma and the neighbouring Saint-Joseph-d'Alma. Inc. city, 1958. Pop. (1991) 25,910.

Alma, city, Gratiot county, central Michigan, U.S., on the Pine River, some 50 miles (80 km) north of Lansing. Founded in 1853, it is in the heart of an agricultural area producing beans, corn (maize), and sugar beets. Light industry and petroleum and sugar-beet refining are of economic importance. The city is the seat of Alma College (founded 1886)

and the Michigan Masonic Home, Inc. village, 1872; city, 1905. Pop. (1990) 9,034.

Alma, Battle of the (Sept. 20, 1854), victory by the British and the French in the Crimean War that left the Russian naval base of Sevastopol vulnerable and endangered the entire Russian position in the war.

Commanded by Prince Aleksandr Menshikov, the Russians had occupied a position on the heights above the Alma River in the southwestern Crimea, thus blocking the road to Sevastopol. The allies landed in the Crimea (September 14) to capture Sevastopol, and under the command of Lord Raglan and Marshal Armand de Saint-Arnaud they attacked the Russians. Although they repulsed the allies' first assault, the alarmed Russians withdrew their artillery; subsequent allied attacks forced the Russians to retreat toward Sevastopol, which was then poorly fortified. The allies, however, failed to pursue the Russians immediately and lost an opportunity to capture the city easily.

Alma-Ata (city, Kazakhstan): see *Almaty*.

Alma-Tadema, Sir Lawrence (b. Jan. 8, 1836, Dronrijp, Neth.—d. June 25, 1912, Wiesbaden, Ger.), painter of scenes from everyday life in the ancient world who enjoyed an immense popularity in his time.

The son of a Dutch notary who intended him for a medical career, Alma-Tadema studied art at the Antwerp Academy (1852–58) under the historical painter Hendrik Leys, assisting his master in 1859 with frescoes for the Stadhuis, Antwerp. During a visit to Italy in 1863, Alma-Tadema became interested in Greek and Roman antiquity and Egyptian archaeology, afterward depicting subjects almost exclusively from those sources. Moving to England, he became a naturalized British subject in 1873 and was elected a member of the Royal Academy in 1879. He was knighted in 1899. Alma-Tadema excelled at the accurate re-creation of ancient settings and costumes and the precise depiction of textures of marble, bronze, and silk. His treatment of human figures is a mixture of restrained sentimentalism and coy anecdote.

Almadén, town, Ciudad Real provincia, in the *comunidad autónoma* ("autonomous community") of Castile-La Mancha, west-central Spain. Almadén is located in one of the world's richest mercury-producing regions.

The town, originally Roman, then a Moorish settlement (Arabic: al-Ma'din, "mine"), was captured by Alfonso VII in 1151 and given to the military-religious Knights of the Order of Calatrava, who exploited the mercuric ores. The king of Spain, Charles I (Holy Roman Emperor Charles V), granted the mines to the German Fugger family of merchant-bankers from 1525 to 1645 as security for a loan. From 1645 the mines were worked by the royal exchequer but leased to the Rothschild banking family in London. Mining remains the chief economic activity of Almadén, which is the seat of two mining academies. Cereals and livestock are raised in the surrounding area, and there are flour mills and shoe factories in the town proper. Pop. (1991 prelim.) 7,723.

Almagest, astronomical and mathematical encyclopaedia compiled about AD 140 by Ptolemy (Claudius Ptolemaeus of Alexandria). It served as the basic guide for Arab and European astronomers until about the beginning of the 17th century. The name, corrupted from

the Arabic, means "the greatest"; among other names given to the work were "The Great Treatise," "The Great Astronomer," and "The Mathematical Collection." It was first translated into Arabic in 827 and retranslated from Arabic to Latin in the last half of the 12th century.

The *Almagest* is divided into 13 books. Book One gives, in broad outline, the geocentric, or Ptolemaic, plan of the solar system. Book Two contains the earliest surviving work on trigonometry: a table giving the values of chords of a circle at intervals of $\frac{1}{2}^\circ$, accurate to at least five places; and studies in the solution of spherical triangles. Book Three deals with the motion of the Sun and the length of the year; Book Four deals with the Moon and the month, as does Book Five, which also takes up the distances of Sun and Moon and tells how to construct an astrolabe. Eclipses are treated in Book Six, as also are planetary conjunctions and oppositions.

Books Seven and Eight mainly concern the fixed stars, giving ecliptic coordinates and magnitudes for 1,022 of them. This star catalog is based on that of Hipparchus (129 BC); those two books also discuss precession and the construction of celestial globes. The remaining five books, the most original, set forth in detail the Ptolemaic system outlined in Book One.

Almagro, Diego de (b. 1475, Almagro, Castile [Spain]—d. 1538, Cuzco, Peru), Spanish soldier who played a leading role in the Spanish conquest of Peru.

Following service in the Spanish navy, Almagro arrived in South America in 1524 and, with his intimate friend Francisco Pizarro, led the expedition that conquered the Inca empire in what is now Peru. Almagro and Pizarro became joint captains general of these conquests, which the Spaniards called New Castile. Bitter enmity soon arose between Almagro and Pizarro, however, leading to much political instability in the new colony.

In 1534 King Charles I of Spain (also Holy Roman emperor as Charles V) sent Almagro to assist in the conquest of what is now Chile, where he is said to have suffered great hardships. During Almagro's absence, Indians in Peru rebelled and even besieged the Spanish fortress of Cuzco. Almagro rushed back to Peru, put down the insurrection, and then imprisoned Pizarro's two brothers Hernando and Alonso for having refused to obey his orders during the fighting. This brought Francisco Pizarro to Cuzco, where he defeated Almagro's army, captured Almagro, and put him to death in the first of several internecine wars between the Spanish captains in the new colony.

Almalyk (Uzbekistan): see *Olmaliq*.

almanac, book or table containing a calendar of the days, weeks, and months of the year; a record of various astronomical phenomena, often with weather predictions and seasonal suggestions for farmers; and miscellaneous other data. An almanac provides data on the rising and setting times of the Sun and Moon, the phases of the Moon, the positions of the planets, schedules of high and low tides, and a register of ecclesiastical festivals and saints' days. The term "almanac" is of uncertain medieval Arabic origin; in modern Arabic, *almanākh* is the word for the weather.

The first printed almanac appeared in Europe in 1457, but almanacs have existed in some form since the beginnings of astronomy. Ancient Egyptian and Greek calendars showed festival dates and days thought to be lucky or unlucky, while the Roman *fasti*, which named days upon which business could or could not be conducted, were later elaborated into lists resembling modern almanacs. Medieval psalters and missals usually contained calendars listing the various holy days, and 12th-

century manuscripts containing tables on the movements of the heavenly bodies are still extant.

Almanacs began to gain real prominence only after the development of printing. The German astronomer Regiomontanus (Johann Müller) published one of the most important early almanacs in 1473 under the title *Ephemerides ab anno*. Most early printed almanacs in England were published by the Stationer's Company; the most famous of them is the *Vox Stellarum* of Francis Moore, which was first published in 1700. These early printed almanacs devoted as much space to astrology and prophecies and predictions of the future as they did to basic calendrical and astronomical data. With the development of Western science in the 17th and 18th centuries, the more sensational elements gradually disappeared from their pages, and scientific almanacs developed into the modern ephemeris, containing rigorously exact tables of astronomical data.

Meanwhile, in both Europe and the New World, the popular almanac was developing into a genuine form of folk literature containing, in addition to calendars and weather predictions, interesting statistics and facts, moral precepts and proverbs, medical advice and remedies, jokes, and even verse and fiction. Guided by the almanac, the farmer was able to tell the time of day and to estimate the proper time to begin seasonal farm work. The almanac also furnished much incidental information that was instructive and entertaining and greatly appreciated where reading matter was scarce. The first almanac printed in colonial North America was *An Almanac for New England for the Year 1639*, compiled by William Pierce and printed in Cambridge, Mass., under the supervision of Harvard College. This was followed by many other American almanacs, one of the best of which, the *Astronomical Diary and Almanack*, was begun by Nathaniel Ames of Dedham, Mass., in 1725 and published until 1775. Benjamin Franklin's brother James printed *The Rhode Island Almanac* in 1728, and Benjamin Franklin (under the nom de plume of Richard Saunders) began his *Poor Richard's* almanacs, the most famous of American almanacs, in Philadelphia in 1732. *Poor Richard's*, enlivened by Franklin's shrewd wit and straightforward prose style, remained a best-seller in the American colonies until sold by him in 1758.

Modern-day almanacs are of several types. The traditional type survives in the *Old Farmer's Almanac*, which has been continuously published in the United States since 1792. But the best-known type of almanac is now a handy and dependable collection of a vast array of statistical, historical, and other information. Notable English-language examples of this type include *The World Almanac and Book of Facts*, which was first published in 1868, the *Information Please Almanac* (from 1947), and the *Reader's Digest Almanac* (from 1965).

almandine, either of two semiprecious gemstones: a violet-coloured variety of ruby spinel (*q.v.*) or iron aluminum garnet, which is most abundant of the garnets. Specimens of the garnet, frequently crystals, contain up to 25 percent grossular or andradite and are commonly brownish red; gem-quality stone is deep red and slightly purple. Almandine, the so-called precious garnet, is most often faceted for rings. Cabochon-cut (rounded, convex polished surface), deep red almandine is called carbuncle; its base is often hollowed to lighten its colour. When rutile needles are included in the almandine, the cabochons often show a four-rayed asterism (star-shaped figure).

Almandine is usually found mixed with both pyrope and spessartine. It occurs in metamorphic rocks, where its presence indicates the

Almandine garnet from Southbury, Conn.

grade of metamorphism. For detailed chemistry and occurrence, see garnet.

Almansa Dam, dam on the Vega de Belén River, in Albacete province, Castile-La Mancha autonomous community, Spain. It is said to be the oldest masonry gravity dam still in use. Probably built in the 16th century, the slender structure has cut-stone facing and a rubble masonry interior. It is 82 feet (25 m) high, 295 feet (90 m) long, and 7,500 cubic yards (5,700 cubic m) in volume and has a reservoir capacity of 1,300 acre-feet (1,600,000 cubic m).

Almaty, Russian ALMA-ATA, formerly (1855–1921) VERNY, city and capital of Kazakhstan. It lies in the northern foothills of the Trans-Alay Alatau at an elevation of 2,300–3,000 feet (700–900 m), where the Bolshaya and Malaya Almaatinka rivers emerge into the plain. The modern city was founded in 1854 when the Russians established the military fortification of Zailiyskoye (renamed Verny in 1855) on the site of the ancient settlement of Almaty, which had been destroyed by the Mongols in the 13th century. Cossacks, peas-

Ballet and opera house at Almaty, Kazakhstan

Novosti Press Agency

ant settlers from European Russia, and Tatar merchants soon established themselves in the vicinity, and in 1867 the fortification became the town of Verny and the administrative centre of newly created Semirechye province of the governorate-general of Turkistan. By 1906 the population had grown to 27,000, two-thirds of whom were Russians and Ukrainians. Soviet rule was established in 1918.

In 1921 the city was renamed Alma-Ata, after its Kazakh name, Almaty (literally "Father of Apples"), alluding to the many apple trees in the locality. The transfer of the Kazakh capital from Kzyl-Orda (Kazakh: Qyzylorda) to Alma-Ata in 1929 and the completion of the Turk-Sib Railway in 1930 brought rapid growth, and the population rose from 46,000 in 1926 to 221,000 in 1939. A number of food and light-industrial factories were built, and heavy industry, particularly machine building, developed later on the basis of plants evacuated from European Russia during World War II. After Kazakhstan obtained its independence from the Soviet Union in 1991, the city's name was changed from its Russian

form, Alma-Ata, to its Kazakh form, Almaty. In 1994 the government decided to gradually transfer the national capital from Almaty to Aqmola in the following years.

The city is located in an area of extensive geologic risk, being subject to both earthquakes and mud slides. The city suffered from severe earthquakes in 1887 and 1911, and a mudflow down the Malaya Almaatinka River in 1921 caused considerable destruction and loss of life. To reduce the risk of future mud slides, an artificial landslide was precipitated by explosives in 1966 to dam the nearby Medeo gorge; the 330-foot (100-metre) dam that resulted proved its worth in 1973 by holding back a potentially catastrophic mud slide. Later improvements have raised the dam to 460 feet (140 m) and further improved the security of the city.

Almaty is now a major industrial centre, with the food industry accounting for about one-third of its industrial output and light industry for about one-fourth. There are a number of institutions of higher education, including the Kazakh Al-Farabi State University (founded 1934), and teacher-training, economics, polytechnic, agricultural, and medical institutes. The city also houses Kazakhstan's Academy of Sciences and its many subordinate research institutes, numerous museums, an opera house, theatres producing in Russian, Kazakh, and Uighur, and the Pushkin State Public Library. Almaty also has a botanical garden, a zoo, and several stadiums.

Almaty now extends about 12.5 miles (20 km) in all directions from its centre and is considered one of the most beautiful cities of Kazakhstan, with regular planning, wide, tree-lined streets, numerous parks and orchards, and a backdrop of mountains. The former Ascension Cathedral, built in 1907 and the second highest wooden building in the world, now houses a museum. Of the population,

Russians make up about 60 percent, with the remainder made up chiefly of Kazakh (less than one-quarter), Ukrainian, Uighur, Tatar, and German minorities. Pop. (1991 est.) 1,156,200.

Almeida, Francisco de (b. c. 1450, Lisbon, Port.—d. March 1, 1510, Table Bay [modern Cape Town, S.Af.]), soldier, explorer, and the first viceroy of Portuguese India.

After Almeida had achieved fame in the wars against the Moors, the Portuguese king Manuel I made him viceroy of the newly conquered territories of India in March 1505. Setting forth with a powerful fleet of 21 ships, he rounded the Cape of Good Hope and, sailing up Africa's east coast, took Kilwa (in what is now Tanzania), where he constructed a fort, and then destroyed Mombasa before reaching India and taking up residence in Cochin. Determined to make Portugal the paramount power in the East and to monopolize the spice trade, he erected a series of fortified posts. Under his forceful administration a commercial treaty was concluded with

Malacca (now Melaka, Malaysia) and further explorations were undertaken, especially by his son Lourenço. When the Arabs and their Egyptian allies challenged Portuguese dominance, he burned and pillaged their ports and defeated their combined fleet off Diu, India, in February 1509.

When Afonso de Albuquerque arrived at Cochin to supersede him, Almeida, doubting the legality of his commission, imprisoned him. In November 1509, however, he was forced to recognize Albuquerque's authority and set sail for Portugal the next month. While taking on water at Table Bay, Almeida was killed in a skirmish with the Khoikhoi (Hottentots).

Almeida, José Américo de (b. Jan. 10, 1887, Paraíba, Brazil—d. March 10, 1980, Rio de Janeiro), novelist whose works marked the beginning of a major Brazilian generation of northeastern regional writers. Their fiction presents a largely socioeconomic interpretation of life in Brazil's most impoverished and drought-stricken region and is filled with local colour and appeals for justice and concern.

Almeida's literary career was paralleled by a career in politics; he served in the first cabinet of President Getúlio Vargas as minister of public works and transportation (1930–34) and was governor of the state of Paraíba (1951–54).

The problems endemic to the Brazilian northeast, including banditry in the arid backlands and the poverty and ignorance of the sugarcane workers in the more fertile coastal zone, are the focus of Almeida's novels. *A Bagaceira* (1928; *Trash*), his best-known work, deals with a group of *sertanejos* (independent smallholders) forced by drought to leave their own ranches for a life of near-slavery on tropical sugar plantations. Other works in the same vein are *O Boqueirão* (1935; "The Canyon") and *Coiteiros* (1935; "Bandit-hiders").

Almeida, José Valentim Fialho de (b. 1857, Vila de Frades, Port.—d. March 4, 1911, Alentejo), Portuguese short-story writer and political essayist of the realist-naturalist period.

Almeida's serial story collection *Os Gatos* (1889–93; "The Cats") is a satiric, caricatural depiction of Lisbon life and customs of the period. In *O País das Uvas* (1893; "Vineyard Country") and other short-story collections, he offers lively, earthy descriptions of rural Portuguese life, which he contrasts favourably with the decadence of the cities. Other collections of short narratives in the satiric vein are *Pasquinadas* (1890; "Lampoons"), *Vida Irônica* (1892; "Ironic Life"), and *Lisboa Galante* (1890; "Courtly Lisbon").

Almeida, Lourenço de (d. 1508, Chaul, India), Portuguese sea captain and leader of a 1505 expedition to Ceylon (now Sri Lanka), probably the first Portuguese voyage to that island.

The son of Francisco de Almeida, the first viceroy of Portuguese India (1505–09), Lourenço de Almeida had been sent by his father to explore the Maldives, to establish alliances, and to form trade relations. Almeida brought Portuguese influence to the region, founding a settlement at Colombo in 1505.

The deflection of Arab and Egyptian trade brought conflict. Almeida defeated an Arab fleet off the west coast of India in 1506 and a fleet from Malacca in 1508 near Chaul. There, however, he was trapped by an Egyptian armada. He fought with bravery, and his exploits were later celebrated by the 16th-century Portuguese poet Camões in his patriotic epic poem *Os Lusíadas* (*The Lusíads*, referring to the ancient Roman territory, Lusitania, that embraced what became Portugal). Almeida

died of wounds received in the battle. Two years later the Portuguese scattered a combined Turkish and Muslim fleet near the port of Diu, finally establishing Portuguese power in much of the territory east of Suez.

Almeida, Manuel Antônio de (b. 1831, Magé, Rio de Janeiro—d. Nov. 28, 1861, at sea), author of what is now considered to have been the first great novel in Brazilian literature, *Memórias de um Sargento de Milícias* (anonymously in parts, 1853; as a novel, 1854–55; “Memoirs of a Militia Sergeant”), his only fictional work. Its realism was not only far in advance of the Romanticism of his Brazilian contemporaries but several years in advance of the Naturalist school in Europe. It attracted little critical or popular attention until it was rediscovered by the Modernists in the 20th century.

Almeida studied art and, later, medicine, but his education was frequently interrupted for lack of money, and he supported himself as a translator and journalist. He became minister of the National Printing Establishment, where he befriended a young typographer and aspiring writer, Machado de Assis, who later became the literary giant of Brazil.

The “Memoirs” mirrors the life of Rio de Janeiro in the early 19th century with a sense of everyday reality. Written in an intimate, colloquial style, it offers a vivid glimpse of customs, personalities, and court intrigues, viewed by Leonardo, a young man of slight social standing, who seeks adventure where he finds it—among beggars, society women, priests, or sailors.

Almeida's promising career was cut short when he died at 31 in a shipwreck off the Brazilian coast while on a newspaper assignment.

Almelo, gemeente (municipality), Overijssel provincie (province), eastern Netherlands, at the junction of the Overijssel Canal and the Almelo-Nordhorn branch of the Twente Canal; it comprises the former municipalities of Ambt-Almelo, Stad-Almelo, and Vriezenveen.

An independent barony belonging to the van Rechteren family, Almelo was acquired through marriage (1350) by the lords of Heeckeren, who also gained the countship of Limburg in 1711. A branch of the family still holds the seat and the Huis te Almelo castle (1662–64).

Almelo shared in the rapid growth of the Twente district in the late 19th century. It is now a textile and metallurgical centre and rail junction. Among its notable buildings are the 17th-century Dutch Reformed Church, the 16th-century town hall (now a tourist office), and the Weighhouse, incorporating an art gallery. Pop. (1999 est.) 66,080.

almemar (Judaism): see bimah.

Almendares River, Spanish RÍO ALMENDARES, river of La Habana province, western Cuba, rising at about 740 ft (225 m) in the Alturas (heights) de Bejucal and flowing in a semicircle north and west, then northward across the Cuban coastal plain through the city of Havana to empty into the Straits of Florida after a course of 29 mi (47 km). It is the source of part of Havana's water supply, and its banks are also the site of the much-frequented Parque Almendares.

Almendros, Nestor (b. Oct. 30, 1930, Barcelona, Spain—d. March 4, 1992, New York, N.Y., U.S.), cinematographer and recipient of an Oscar from the U.S. Motion Picture Academy of Arts and Sciences for the best cinematography for his work on *Days of Heaven* (1978).

Emigrating from Spain to Cuba in 1948, Al-

mendros worked there for several years and made amateur films with Tomás Gutiérrez Alea and other young Cuban enthusiasts. He spent a year in Rome at the Centro Sperimentale and then taught for a while in the United States. While there, he became friendly with underground filmmakers Maya Deren and Adolfo and Jonas Mekas. Almendros returned to Cuba after the revolution in 1959 and worked on several documentaries of the early Castro era but found the film industry there too bureaucratic.

Almendros moved to France in 1961, where he did film shorts and television work. His first feature film and his first film in 35-millimetre format was Eric Rohmer's *La Collectionneuse* (1966). He also filmed *Ma nuit chez Maud* (1968; *My Night at Maud's*), *Le Genou de Claire* (1970; *Claire's Knee*), and *L'Amour, l'après-midi* (1972; *Chloe in the Afternoon*) for Rohmer. With François Truffaut he did *L'Enfant sauvage* (1970; *The Wild Child*), *Domicile conjugal* (1970; *Bed and Board*), and *Les Deux Anglaises et le continent* (1971; *Two English Girls*). His later films included the popular *L'Amour en fuite* (1979; *Love on the Run*). Almendros' autobiography, *A Man with a Camera*, was published in 1984.

Almería, province in the autonomous community (region) of Andalusia, southeastern Spain, bordering the Mediterranean. Formed in 1833, it has an area of 3,388 sq mi (8,774 sq km). Primarily mountainous, it is crossed by sierras in which terminate successive zones of the Penibético Mountain System. The intervening valleys of the Adra, Almanzora, and Andarax rivers provide the only fertile land. Despite a low rainfall, several important irrigation systems have considerably increased cultivation. The infrequency of cloud cover over the province (unusual in Europe) made it the site in 1979 of a major Spanish-West German astronomical observatory at Calar Alto. Fruit growing is the principal agricultural activity, and large quantities of oranges and white grapes are exported. Olive oil, cane and beet sugar, almonds, and esparto are also produced.

Livestock is raised, especially sheep. Mineral resources include iron, lead, and gold, and fine marble is quarried in the Sierra Nevada of the Penibético. There is a flourishing ceramics industry at Níjar. Tourism is of importance because of the year-round resort areas along the Mediterranean coast. The village of Tabernas became in 1980 the site of two 500-kilowatt solar power plants that were to be among the world's most advanced at their completion.

Communications focus on Almería, the provincial capital and seaport. Other chief towns are Adra, Berja, Cuevas del Almanzora, Huércal-Overa, and Garrucha. Pop. (1996 est.) 501,761.

Almería, port city and capital of Almería province, in the autonomous community (region) of Andalusia, southern Spain, on the Mediterranean Golfo de Almería. Known to the Romans as Urci or Portus Magnus and to the Moors as al-Mariyah (Mirror of the Sea), it was captured by the Catholic monarchs Fer-

Old northwest section of Almería, Spain

Richard Wilkie—Black Star

dinand and Isabella of Castile in 1489. Historic landmarks include the Gothic cathedral (1524–43), built in the form of a fortress; the bishop's palace and seminary in the Moorish Alcazaba (fortress), built in 773 by the Amir of Córdoba, 'Abd ar-Rahmān I, on the site of a Phoenician settlement; and the ruined Castillo de San Cristóbal, which overlooks the city and harbour.

Almería's architecture and dazzling brightness give it a Moroccan rather than a European appearance. The mild and sunny climate, which permits year-round swimming, gives Almería its claim to be the resort centre of the Costa de La Luz (part of the Spanish Mediterranean coast). After 1960 the locale became popular with filmmakers, stimulating the building of hotels and the growth of airport facilities.

Industrial activities include metalworking, canning and salting of fish, refining of oil and sulfur, and manufacture of chemicals. A major cement complex (including quarry, plant, and port) was built in the late 1970s at Carboneras Beach. The port, which is sheltered and equipped with modern facilities, is especially busy from August to December because of the export of oranges and grapes. Pop. (1998 est.) 168,025.

Almetyevsk, also spelled ALMETEVSK, or AL'METJEVSK, city, Tatarstan, Russia, on the left bank of the Stepnoy (Steppe) Zay River. It was founded in 1950 in connection with the discovery of petroleum in the area. Crude oil is sent from Almetyevsk to refineries at Perm and Kstovo (near Nizhny Novgorod) through pipelines completed in 1957. Almetyevsk is also the primary source of crude oil piped to eastern Europe. Local factories produce tires and ferroconcrete materials. Pop. (1997 est.) 140,000.

Almirante Brown, cabecera (principal built-up area) and *partido* (political subdivision) of Gran (Greater) Buenos Aires, Argentina, south of the city of Buenos Aires, in Buenos Aires province. The *partido* was founded in 1873 and the *cabecera* is often referred to as Adroqué, the name of its founder, and its railroad station bears that name. Esteban Adroqué petitioned the provincial government to expropriate land from the existing *partidos* of San Vicente and Quilmes to establish the new one. The original settlers were residents of Buenos Aires city who fled the capital during an epidemic of yellow fever. The *partido* covers 47 sq mi (122 sq km) and is bordered by the *partidos* of Lomas de Zamora (north), Quilmes and Florencio Varela (east), San Vicente (south), and Esteban Echeverría (west). Besides the *cabecera*, Almirante Brown, the major localities are Burzaco, Longchamps, Glew, Ministro Rivadavia, Claypole, Rafael Calzada, and José Mármol. In 1886 Adroqué unveiled a statue in the central plaza honouring Adm. Guillermo Brown (hero of the 1827 naval battle of Junca, in which Argentine warships defeated a Brazilian fleet). The *cabecera* and *partido* grew slowly in the late 19th and early 20th centuries. By 1947 the region began growing at an accelerated rate as the urbanization of Buenos Aires city started to spill over to surrounding *partidos*. Since then, Almirante Brown has been absorbed into the southern suburban fringe of Gran Buenos Aires. About half of the *partido* is within Gran Buenos Aires urban area, and its density of settlement is lower than in the more urbanized *partidos*. Livestock is raised in the area, and there are textile mills and dairies. Pop. (1999 est.) *partido*, 550,000.

Almohads, Arabic AL-MUWAḤḤIDŪN (Those Who Affirm the Unity of God), a Berber confederation that created an Islāmic empire in North Africa and Spain (1130–1269), founded on the religious teachings of Ibn Tūmart (d. 1130).

A Berber state had arisen in Tinmel in the Atlas Mountains of Morocco c. 1120, inspired by Ibn Tūmart and his demands for puritanical moral reform and a strict concept of the unity of God (*tawhīd*). In 1121 Ibn Tūmart proclaimed himself the *mahdī* (a promised messianic figure), and, as spiritual and military leader, began the wars against the Almoravids. Under his successor, 'Abd al-Mu'min, the Almohads brought down the Almoravid state in 1147, subjugating the Maghrib, and captured Marrakech, which became the Almohad capital. Almoravid domains in Andalusia, however, were left virtually intact until the caliph Abū Ya'qūb Yūsuf (reigned 1163–84) forced the surrender of Seville in 1172; the extension of Almohad rule over the rest of Islāmic Spain followed. During the reign of Abū Yūsuf Ya'qūb al-Manšūr (1184–99) serious Arab rebellions devastated the eastern provinces of the empire, whereas in Spain the Christian threat remained constant, despite al-Manšūr's victory at Alarcos (1195). Then, at the battle of Las Navas de Tolosa (1212), the Almohads were dealt a shattering defeat by a Christian coalition from Leon, Castile, Navarre, and Aragon. They retreated to their North African provinces, where soon afterward the Hafṣids seized power at Tunis (1236), the 'Abd al-Wādids took Tilimsān (Tlemcen) (1239), and, finally, Marrakech fell to the Marīnids (1269).

The empire of the Almohads had kept its original tribal hierarchy as a political and social framework, with the founders and their descendants forming a ruling aristocracy; however, a Spanish form of central government was superimposed on this Berber organization. The original puritanical outlook of Ibn Tūmart was soon lost, and the precedent for building costly Andalusian monuments of rich ornamentation, in the manner of the Almoravids, was set as early as Ibn Tūmart's successor 'Abd al-Mu'min. The Booksellers' Mosque (Kutubiyah) in Marrakech and the older parts of the mosque of Taza date from his reign. Neither did the movement for a return to traditionalist Islām survive; both the mystical movement of the Šūfīs and the philosophical schools represented by Ibn Ṭufayl and Averroës (Ibn Rushd) flourished under the Almohad kings.

Rabat, an important cultural centre during the Almohad period, was known particularly for its polychrome pottery. The wares are colourful and gay, usually painted in yellows, greens, and bright blues on a buff background. Almohad pottery wares, however, never reached the artistic level of the work from Syria, Egypt, and Persia, and most are considered products of "folk" rather than "fine" art.

Almon, John (b. Dec. 17, 1737, Liverpool, Eng.—d. Dec. 12, 1805, Boxmoor, Hertfordshire), English parliamentary reporter and political writer, who took part in the struggle between press and Parliament for the right to publish reports of debates.

A friend of the political reformer John Wilkes, he became known in the early 1760s as a Whig pamphleteer and as a bookseller from whose London shop political publications were disseminated. His parliamentary reports, published in the *London Evening Post*, precipitated a crisis between printers and Parliament in 1771; others followed the example of the *Post*. Wilkes used his privileged position as alderman of the City of London to prevent the arrest of printers and put an end to Parliament's power to punish journalists who reported its debates. Almon's article in the *Post* (1773) accusing John Montagu, 4th earl of Sandwich, of selling an office of trust cost the *Post*'s printer a £2,000 fine. Almon himself was once imprisoned for libel and once forced to flee the country. In 1774 he began *The Parliamentary Register*, a monthly record of proceedings (continued until 1813). His printed

attacks on William Pitt in the 1780s brought his imprisonment for 14 months (1792–93), and he lived the rest of his life on bail.

almond (*Prunus dulcis*), tree native to southwestern Asia and its edible seed, or nut. The nuts are of two types, sweet and bitter. Sweet almonds are the familiar edible type consumed as nuts and used in cooking or as a source of almond oil or almond meal.

Almond (*Prunus dulcis*)
Grant Heilman—EB Inc

The almond tree, growing somewhat larger than the peach and living longer, is strikingly beautiful when in flower. The growing fruit resembles the peach until it approaches maturity; as it ripens, the leathery outer covering, or hull, splits open, curls outward, and discharges the nut.

The sweet almond is cultivated extensively in certain favourable regions between 28° and 48° N and between 20° and 40° S. The tree greatly resembles the related peach, with which it occasionally hybridizes. While dormant, it is nearly as hardy as the peach, although ordinarily flowering earlier, from late January to early April north of the Equator. The nut crops are therefore uncertain wherever frosts are likely to occur during the period of flowering. Sweet almonds mature only occasionally in climates like that of southern England.

The Old World almond cultivation was characterized by small plantings mainly for family use; trees interplanted with other crops; variability in age, condition, and bearing capacity of individual trees; and hand labour, often with crude implements. Modern growers pay more attention than they once did to propagation of approved varieties. Jordan and Valencia almonds come from Spain. Leading almond-producing countries during the early 2000s were the U.S., Spain, Syria, Iran, and Italy.

Bitter almonds, as inedible as peach kernels, contain about 50 percent of a fixed oil that also occurs in the sweet almond, together with an enzyme called emulsin, which in the presence of water yields glucose, prussic (hydrocyanic) acid, and the essential oil of bitter almonds called benzaldehyde. When the prussic acid has been removed, the oil of bitter almonds is used in the manufacture of flavouring extracts for foods and liqueurs.

Almonds provide small amounts of protein, iron, calcium, phosphorus, and B vitamins and are high in fat. They may be eaten raw, blanched, or roasted and are commonly used in confectionery baking. In Europe a sweetened paste made from almonds is used in pastries and in marzipan, a traditional candy. The almond is also widely used in meat, poultry, fish, and vegetarian dishes of Asia.

Almond, Gabriel A(braham) (b. Jan. 12, 1911, Rock Island, Ill., U.S.—d. Dec. 25, 2002, Pacific Grove, Calif.), American politi-

cal scientist noted for his comparative studies of political systems and his analysis of political development.

Almond received a Ph.D. from the University of Chicago in 1938 and taught at Brooklyn College from 1939 to 1946, except for service in the U.S. Office of War Information in 1942–45. After teaching at Yale University (1947–51 and 1959–63) and at Princeton University (1951–59), he became a professor of political science at Stanford University, Stanford, Calif., in 1963 (emeritus 1976), heading the department there from 1964 to 1968. He was elected president of the American Political Science Association for 1965–66 and was its James Madison lecturer in 1981.

Among Almond's publications are *The Struggle for Democracy in Germany* (1949; written with others and edited by Almond); *The American People and Foreign Policy* (1950); *The Appeals of Communism* (1954); *The Politics of the Developing Areas* (1960; written with others and edited by Almond), in which he presented a functional approach to the study of political systems; *The Civic Culture* (1963, with Sidney Verba), a cross-cultural study of citizen attitudes toward government in five societies; *Political Development* (1970); and *Plutocracy and Politics in New York City* (1998). He also wrote, with others, *Comparative Politics: System, Process, Policy* (1978), *The Civic Culture Revisited* (1980), *Progress and Its Discontents* (1982), and *European Politics Today* (1999).

almoner, originally, an officer responsible for distributing alms to the poor, usually connected with a religious house or other institution but also a position with some governments. In the 13th century, almoners were attached to the French court to distribute the royal alms, and in 1486 the office of grand almoner of France was established. The grand almoner was a high ecclesiastical dignitary who was in charge of the clergy attached to the court and who supervised charitable works. The office was suppressed in France in 1790, revived by Napoleon I and again by Napoleon III, and finally abolished in 1870.

In England the offices of hereditary grand almoner and high almoner still exist, as part of the Queen's Household. The high almoner, usually a bishop or other prelate, distributes the royal alms on Maundy Thursday.

In modern times the term almoner has also been used in Britain for a trained social worker, usually a woman, qualified to work in a medical setting. In this sense "almoner" was superseded in 1964 by the title medical social worker, the term also used in the United States. Medical social workers are employed by hospitals and public health departments.

almonry school, medieval English monastic charity school supported by a portion of the funds allocated to the almoner (*q.v.*). The practice began in the early 14th century when a form of scholarship was established that provided attendance at the cathedral school, housing, and food for boys at least 10 years old who could sing and read. They sang in the cathedral choir and acted as page boys to the monks. Their teachers were the secular clerks of the monastery. Such schools have now largely disappeared, although a few survived into the 20th century.

Almora, town, administrative headquarters of Almora district, Uttaranchal state, northern India, on a ridge of the Himalayan foothills. After the Gurkhas captured Almora in 1790, they built a fort on the ridge's eastern end; another fort stands on the western end. The Gurkhas suffered a defeat by the British near Almora in 1815. An agricultural trade centre, it also has some manufacturing and a college

affiliated with Kumaun University. A road links the town with cities to the south.

Almora district has an area of 2,085 sq mi (5,400 sq km). It lies within the Himalayas and borders on Nepal. Much of the district is forested; its irregular topography has confined agriculture largely to the river valleys. Rice, wheat, fruit, millet, and tea are among the crops grown. Minerals include copper and magnetite deposits. Major towns are Almora and Rānikhet. Pop. (1991) town, 26,001; metropolitan area, 28,051; district total, 836,617.

Almoravids, Arabic AL-MURĀBIṬŪN (Those Dwelling in Frontier Fortresses), confederation of Berber tribes—Lamtūnah, Gudālah, Massūfah—of the Ṣanhājah clan, whose religious zeal and military enterprise built an empire in northwestern Africa and Muslim Spain in the 11th and 12th centuries. These Saharan Berbers were inspired to improve their knowledge of Islāmic doctrine by their leader Yaḥyā ibn Ibrāhīm and the Moroccan theologian 'Abd Allāh ibn Yasīn. Under Abū Bakr al-Lamtūnī and later Yūsuf ibn Tāshufin, the Almoravids merged their religious reform fervour with the conquest of Morocco and western Algeria as far as Algiers between 1054 and 1092. They established their capital at Marrakech in 1062. Yūsuf assumed the title of *amīr al-muslimīn* ("commander of the Muslims") but still paid homage to the 'Abbāsīd caliph (*amīr al-mu'minīn*, "commander of the faithful") in Baghdad. He moved into Spain in 1085, as the old caliphal territories of Córdoba were falling before the Christians and Toledo was being taken by Alfonso VI of Castile and Leon. At the Battle of az-Zallāqah, near Badajoz, in 1086 Yūsuf halted an advance by the Castilians but did not regain Toledo.

The whole of Muslim Spain, however, except Valencia, independent under El Cid (Rodrigo Díaz de Vivar), eventually came under Almoravid rule. In the reign (1106–42) of 'Alī ibn Yūsuf the union between Spain and Africa was consolidated, and Andalusian civilization took root: administrative machinery was Spanish in pattern, writers and artists crossed the straits, and the great monuments built by 'Alī in the Maghrib were models of pure Andalusian art. But the Almoravids were but a Berber minority at the head of the Spanish-Arab empire, and while they tried to hold Spain with Berber troops and the Maghrib with a strong Christian guard, they could not restrain the tide of Christian reconquest that began with the fall of Saragossa in 1118. In 1125 the Almohads began a rebellion in the Atlas Mountains and after 22 years of fighting emerged victorious. Marrakech fell in 1147, and thereafter Almoravid leaders survived only for a time in Spain and the Balearic Isles.

Art of the Almoravid period is most noted for its sobriety and puritanism after the ornamental excesses of the Umayyads. It was only in the "minor," decorative arts of weaving and ivory carving that the Almoravids used ornamentation as an end in itself. Desert dwellers, military ascetics from the Sahara, the Almoravids shunned the lavish decoration that had characterized the late Umayyad architectural style and built on a practical rather than a monumental scale. Even in the secular sphere, piety and asceticism forbade the building of splendid palaces and monuments. The main architectural motif of the period was the horseshoe arch, which in later times was elaborated and used extensively by the Almohads and the Naṣrids. Minarets, usually placed at the corner of the *mīhrāb* (prayer niche facing Mecca), were square and only sparsely decorated. The most famous work to survive from the Almoravid age is the Great Mosque at Tlemcen, Algeria. Built in 1082, it was restored in 1136 but not in true Almoravid

style. The *mīhrāb* is unusually ornate, surrounded by multilobed arches decorated with arabesques. The work is indicative of trends that were to develop in Spain and North Africa under the Almoravids' successors, the Almohads and the Naṣrids.

Almqvist, Carl Jonas Love, Almqvist also spelled ALMQUIST (b. Nov. 28, 1793, Ed, near Stockholm—d. Sept. 26, 1866, Bremen, Bremen), writer whose vast literary output, ranging from bizarre romanticism to bold realism,

Almqvist, detail of an oil painting by C.P. Mazer, 1836, in the Nordiska Museet, Stockholm

By courtesy of the Nordiska Museet, Stockholm

greatly influenced the development of Swedish literature. Although his work is uneven, he is a master of Swedish prose.

After studying at Uppsala, Almqvist entered the Department of Ecclesiastical Affairs in Stockholm. In 1823 he gave up his position and went to western Sweden to lead with a group of friends an idealized peasant existence patterned after the ideas of Rousseau. Two years later he returned to Stockholm, and from 1829 to 1841 was principal of an experimental secondary school. In 1851 he fled to the U.S. after being accused of fraud and the attempted murder of a moneylender. He returned to Europe in 1865.

Almqvist was little known until the mid-1830s when he began to publish a stream of works in prose and verse. Most of these—novels, short stories, poems, and verse dramas—were included in a series called *Törnrosens bok* ("The Book of the Briar Rose"; 13 vol., 1832–40; vol. 14, 1851; 2nd series, 1839–50). Particularly important were *Amorina* (written c. 1821; rewritten and published 1839) and *Drottningens juvelsmycke* (1834; "The Queen's Diamond Ornament"), a historical novel whose heroine, the mysterious, hermaphroditic Tintomara, is Almqvist's most fascinating character and a central symbol in his creative writings. *Det går an* (1838; *Sara Videbeck*, 1919) is a brilliant, realistic story pleading for the emancipation of love and marriage. The work foreshadows Strindberg's method of raising problems for debate. He was also a musician and set some of his short lyrics to music.

Almqvist showed an astonishing versatility. He attacked conventional matrimony, satirized the beliefs of the Lutheran Church (although he was ordained in 1837), and as a journalist and in many of his creative writings fought for moral and social reform. But he had strong tendencies toward egocentric aloofness, and the core of his personality remained dominated by Christian mysticism and Swedenborgian otherworldliness.

almshouse, also called POOR HOUSE, or COUNTY HOME, in the United States, a locally administered public institution for homeless, aged persons without means. Such institutions radically declined in number in the second half of the 20th century, to be replaced by other means of subsistence and care.

Dating from colonial days, it was formerly used as a dumping ground for the mentally ill,

the epileptic, the feeble-minded, the blind, the deaf and dumb, the crippled, the tuberculous, the destitute aged, homeless unemployed, vagrants, petty criminals, prostitutes, unmarried mothers, and abandoned and neglected children. Operated often in conjunction with a farm, with emphasis on meeting costs through the sale of farm produce, the almshouse, or county home, incurred widespread criticism after the turn of the 20th century for its failure to provide differentiated treatment for the varying problems presented by residents, the minimum character of medical and nursing care offered, the low sanitation and safety standards, and the physical and mental deterioration in residents invited by neglect and the incompetence of the management. These evils were gradually but not altogether eliminated by the shift of the sick, the handicapped, and the young to specialized state institutions, a process that began in the middle of the 19th century, and the transfer out of able-bodied aged who could qualify for old-age assistance under the Social Security Act of 1935. From a peak of probably 135,000 in the early 1930s, the population of county homes dropped to an estimated 88,000 in 1940 and to 72,000 in 1950. Residents in 1950 consisted largely of aged infirm individuals. Closings and consolidations reduced the number of homes from 2,200 in 1923 to approximately 1,200 in 1950.

The prohibition in the Social Security Act against federally aided old-age assistance to residents of public institutions reflected a conviction that almshouses were unnecessary; but experience after 1935, particularly the rapid growth of commercial nursing homes, indicated that many aged persons required sheltered care or at least home-supervised care and that, in the absence of other free facilities, the indigent aged will use some kind of local public institution. Recognition in the 1940s of this need came at a time of increasing public awareness of the lack of adequate facilities for the chronically ill long-term patient. As a result, a number of states passed legislation encouraging the conversion of almshouses to county infirmaries. Social security benefits and, later, Medicaid also substantially lessened reliance on public homes, until they became obsolete.

almucantar, in astronomy, any circle of the celestial sphere parallel to the horizon; when two objects are on the same almucantar, they have the same altitude. The term also refers to instruments of a pattern invented by the U.S. astronomer Seth Carlo Chandler for determining latitude or time by observing the times of transit of stars across a fixed almucantar.

Alness, village, Highland council area, historic county of Ross-shire, historic region of Ross and Cromarty, northern Scotland, situated on the northern shore of the Cromarty Firth. The village was planned in the 1970s to accommodate commuters to nearby Invergordon's new industries, in particular an aluminum smelting plant (now closed) and goods and services for the North Sea oil industry; the latter include the construction of the world's largest dry dock and the manufacture of oil rigs. Telecommunications has become a major source of employment in the area. Pop. (1991) 5,696.

alnico, any member of a series of alloys used to make powerful permanent magnets. Primary constituents are aluminum, nickel, and cobalt in various proportions, with small amounts of one or more of the elements copper, iron, and titanium added; the titanium-containing material is sometimes referred to by the trade name Ticonal. These alloys are very hard and difficult to machine; they are usually cast into their final shape and then subjected to a strict regime of heat and magnetic-field treatment.

Alnwick, district, county of Northumberland, northern England, occupying an area of 417 square miles (1,080 square km) that borders Scotland on the northwest and the North Sea on the east. The district descends eastward from the peaty moorlands of the Cheviot Hills (elevations above 2,000 feet [610 m]) along the Scottish border and across the valleys of the upper Aln and Coquet rivers and sandstone uplands of the area known as Rothbury Forest (800–1,400 feet [250–425 m]) to the fertile coastal plain, meeting the North Sea in low cliffs and shallow bays backed by sand dunes.

Sheep are grazed throughout the district, with the hardy Cheviot being the significant breed. Lesser numbers of both beef and dairy cattle are raised in the upper Aln and Coquet valleys and on the coastal plain. Crops cultivated on large farms, especially on the coastal plain, include oats, barley, clover, turnips, and cabbage. The small coastal village of Craster is historically known for its production of kippers (smoked herring). Pop. (1998 est.) 31,400.

Alnwick, town ("parish"), Alnwick district, county of Northumberland, England, on the south bank of the River Aln, between the Cheviot Hills and the sea.

The town is dominated by the Norman castle, since 1309 the principal seat of the Percy family, who later became Earls of Northumberland. The house was rehabilitated in the 18th century under the direction of Robert Adam, and the surrounding park was landscaped by Lancelot ("Capability") Brown. Much of Adam's work in the Gothic style was replaced about 1855 by Anthony Salvin, who converted the interior to an Italian Renaissance-style palace.

Hulne Park and North Demesne are remnants of the ancient hunting grounds of the marcher (border) lords. Parts of the medieval

Aloe saponaria

Alonso, Dámaso (b. Oct. 22, 1898, Madrid, Spain—d. Jan. 24, 1990, Madrid), Spanish poet, literary critic, and scholar, a member of

Alnwick Castle, Northumberland
A.F. Kersting

town wall (notably the Hotspur Tower), the gatehouse of Alnwick Abbey (1147), and the 15th-century grammar school survive. Pop. (1991) 7,419.

Aload, Greek *ALOADA*, or *ALOEIDA*, in Greek legend, the name for either Otus or Ephialtes, the twin sons of Iphimedeia, the wife of Aloeus, by the god Poseidon; they were of extraordinary strength and stature. The Aloads made war upon the Olympian gods and endeavoured to storm heaven itself, but Apollo destroyed them before they reached manhood. In a later myth they sought Artemis (goddess of wild animals, vegetation, and childbirth) and Hera (wife of Zeus) in marriage, whereupon Artemis appeared between them in the shape of a stag, which they attempted to kill but instead slew each other.

Aloe, genus of shrubby succulent plants in the lily family (Liliaceae), containing about 200 species native to Africa. Most members of the genus have a rosette of leaves at the base but no stem.

the group of poets called the Generation of 1927.

Educated at the University of Madrid, Alonso taught at the Centre of Historical Studies, Madrid (1923–36), and was a professor at the University of Valencia (1933–39) and the University of Madrid (1939–68). He was also a lecturer or visiting professor at universities in Germany, Britain, and, frequently, the United States.

His first volume of poems, *Poemas puras* (1921; "Pure Poems"), were imagist, emphasizing economy of expression, but his later poetry evolved into a freer, more complex style, especially in his most famous poetical works, *Oscura noticia* (1944; "Dark Message") and *Hijos de la ira* (1944; *Children of Wrath*). *Poesías escogidas* ("Selected Poetry") appeared in 1969.

As a critic, he helped revive the reputation of the 17th-century Baroque poet Luis de Góngora y Argote with his edition of Góngora's *Soledades* (1927; "Solitudes") and his essay *La lengua poética de Góngora* (1935;

"The Poetic Language of Góngora") and other later works. His mastery of criticism is seen best in *Poesía española* (1950; 5th ed., 1966; "Spanish Poetry"). Alonso also translated the works of such authors as James Joyce, Gerard Manley Hopkins, and T.S. Eliot.

alopecia: see baldness.

Alor Islands, Indonesian *KEPULAUAN ALOR*, group of two major and several lesser islets constituting the Alor *kabupaten* (regency) in Nusa Tenggara Timur *provinsi* ("province"), Lesser Sunda Islands, Indonesia, between the Flores and Savu seas. The largest island is Alor (900 square miles [2,330 square km]), the two major mountains of which, Kolana (5,791 feet [1,765 m]) and Muna (4,724 feet [1,440 m]), are both old volcanoes. Alor is broken up by steep ravines, with only one plateau and some small coastal plains. Pantar Island is high (Mount Delaki is 4,324 feet [1,318 m]), with a rugged coast. The inhabitants speak languages belonging to the Austronesian (Malayo-Polynesian) family. They are animists, except for some Christian communities along the coasts and some Muslims. Festive occasions often involve exchanges of pigs, gongs, and *mokos*, cast-bronze kettle drums of unknown origin. Pop. (1990) 144,620.

Alor Setar, also spelled *ALOR STAR*, town, northwestern West Malaysia, on the Kedah River. The town, neatly laid out, is concentrated on the west bank of the river and is the residence of the sultan of Kedah. Alor Setar is the major distribution centre for the north Kedah plain, a region in which paddy rice is grown. An intervening swamp forest makes it unapproachable from the sea, 12 miles (19 km) to the west, but road and rail services reach north to Thailand and south to Pinang; there also is an airport at Kepala Batas, 6 miles (10 km) north-northeast. Pop. (1991 prelim.) city 125,026; urban agglom. 165,113.

Alost (Belgium): see Aalst.

Aloysius GONZAGA, SAINT (b. March 9, 1568, Castiglione delle Stiviere, Republic of Venice [Italy]—d. June 21, 1591, Rome; canonized 1726; feast day June 21), patron saint of Roman Catholic youth.

A son of Ferrante, marchese di Castiglione, Aloysius was educated at the ducal courts of Florence and Mantua and at the royal court of Madrid, where he was page to King Philip II's son Diego. In 1585 he resigned his inheritance and entered the Society of Jesus (Jesuits) at Rome, where one of his spiritual directors was the renowned theologian Robert Bellarmine. Shortly before ordination, while nursing victims of the plague, he contracted the disease and died.

He was named patron of youth by Pope Benedict XIII in 1729, an action confirmed by Pope Pius XI in 1926.

BIBLIOGRAPHY. Among the many lives of Aloysius Gonzaga are those by Maurice Meschler, *Life of St. Aloysius Gonzaga, Patron of Christian Youth* (1911, reprinted 1985); and C.C. Martindale, *The Vocation of Aloysius Gonzaga* (1927, reissued 1945).

ALP: see Australian Labor Party.

Alp-Arslan, Turkish *ALPARSLAN* ("Courageous Lion"), original name *ʿADUD AL-DAWLĀ ABŪ SHUJĀʾ MUḤAMMAD IBN DĀʿŪD CHAḠHRIBEG* (b. c. 1030—d. November 1072/January 1073), second sultan of the Seljuq Turks (1063–72), who inherited the Seljuq territories of Khorāsān and western Iran and went on to conquer Georgia, Armenia, and much of Asia Minor (won from the Byzantines).

Alp-Arslan was the son of Chaghri Beg, the ruler of Khorāsān in Iran, and the nephew of Toghril, the governor of western Iran, the

base of Seljuq expansion. In 1061 his father died. When, in 1063, his uncle died without issue, Alp-Arslan became sole heir to all the possessions of the dynasty except Kerman, in southern Iran, which was held by one of his brothers, whom he promptly reduced to vassalage. He likewise easily eliminated the son of one of Toghril's widows, as well as Qutlunush, a cousin and rival.

Born outside the traditional Muslim countries that he was later to govern, Alp-Arslan left their administration to his vizier, Nizām al-Mulk, who later continued as administrator under the sultan's son and successor, Malik-Shāh. While maintaining control of Iraq, Alp-Arslan nevertheless shunned that country in order to avoid such clashes of interests with the caliphate, the seat of which was there, as had complicated Toghril's last days.

Alp-Arslan's political activity was based on the ideas that inspired all the three great Seljuq sovereigns. In Central Asia, peace was maintained with the Ghaznavid rulers who were hard to track down in their mountain strongholds in India, whereas against the Qarakhanids of Transoxania, force was used. In the west, where Alp-Arslan was to gain all his glory, he was faced with a more complicated situation. On the one hand, he decided to go to Egypt to crush the Ismā'īlī Fāṭimid heresy, which the 'Abbāsīd Sunnite caliphate at Baghdad, whose protector he was, would not accept. On the other hand, he was aware of the necessity of keeping his influence over the Turkmens, which was essential to his military strength. The Turkmens were interested above all in the success of the holy war against the infidels and in raids on Christian territory. Against the Byzantines and their Armenian and Georgian neighbours, Alp-Arslan conducted a series of campaigns, which were extended by attacks from autonomous Turkmen bands. In 1064 he seized Ani, the former Armenian capital, and Kars. These operations resulted only in some consolidation of boundaries, which assured the Turkmens control over pastureland on the Aras River. Nevertheless, although the Turkmens returned to Muslim territory to store away their booty, these expeditions upset the Byzantine defense system and paved the way for the subsequent Turkish conquest of Asia Minor. They resulted in Byzantine reactions in Syria and Armenia, after which the two empires began to negotiate.

Alp-Arslan then judged himself sufficiently protected on the Byzantine side to undertake, at the request of Egyptian rebels, the great anti-Fāṭimid expedition that had been asked for by the orthodox 'Abbāsīd caliphate. As he was about to attack Aleppo, whose prince was too late in siding with the 'Abbāsīds, and was preparing to occupy Syria, Alp-Arslan learned that the Byzantine emperor Romanus IV Diogenes, with a formidable army, was assaulting his rear army in Armenia. Quickly retracing his steps, he faced his adversary near Manzikert in August 1071. The Byzantine army, powerful in numbers but weak in morale, fell before the outnumbered but dedicated Turks. By evening the Byzantine army was defeated, and, for the first time in history, a Byzantine emperor had become the prisoner of a Muslim sovereign. Alp-Arslan's goal was not to destroy the Byzantine Empire: he was content with the rectification of boundaries, the promise of tribute, and an alliance. But the Battle of Manzikert opened Asia Minor to Turkmen conquest. Later, every princely family in Asia Minor was to claim an ancestor who had fought on that prestigious day.

Alp-Arslan's triumph was followed by a commonplace death, permitting moralists to recall that power rests only in God: at the end of 1072, he had returned to the Qarakhanid

frontier and, during a quarrel, was mortally wounded by a prisoner. He had designated as his heir his son Malik-Shāh, 13 years old, under the guardianship of Nizām al-Mulk.

Alp-Arslan's personality, in spite of the glory surrounding his name, is not easy to evaluate. Muslims see in him a great captain, a trainer of men, an honest man, an enemy of all treachery. Christians, contrasting his reputation with that of his son Malik-Shāh, paint him in harsher colours. There is no doubt that conquest seems to have been his favourite pastime. Although an anonymous writer dedicated to him the *Malek-nāmeḥ*, an attempt to trace the origins of his family and the empire, Alp-Arslan appears to have shown little interest in intellectual matters, leaving them, like the administration of his empire, to his vizier.

(C.C.)

BIBLIOGRAPHY. The discussions of Alp-Arslan in W. Barthold (Vasilii V. Barthold), *Turkestan Down to the Mongol Invasion*, 4th ed. (1977); and Claude Cahen, *Pre-Ottoman Turkey* (1968), may be recommended.

alpaca (*Lama pacos*), South American member of the camel family, Camelidae (order Artiodactyla), that is closely related to the llama, guanaco, and vicuña, which are known collectively as lamoids. The alpaca and the llama were both apparently domesticated several thousand years ago by the Indians of the Andes Mountains of South America. The other two lamoid species, the guanaco and vicuña, exist basically in the wild state.

Alpaca (*Lama pacos*)

Francisco J. Enze/Bruce Coleman Ltd

Like other lamoids, alpacas are slender-bodied animals with a long neck and legs, a short tail, a small head, and large, pointed ears. Alpacas are readily distinguished from llamas by their smaller size; they stand approximately 90 cm (35 inches) high at the shoulder and weigh 55 to 65 kg (121 to 143 pounds). The alpaca also differs from the llama in having a rounded, rather than squarish, body and in its habit of pressing its tail close to the body rather than holding it erect, as does the llama. The alpaca's shaggy coat varies in colour from the usual black or brown through lighter shades of gray and tan to pale yellow and, occasionally, white. The present distribution of alpacas is limited to central and southern Peru and western Bolivia. Alpacas are the most limited in range and the most specialized of the four lamoids, being adapted to marshy ground at altitudes from 4,000 to 4,800 m (13,000 to 15,700 feet). In adaptation to the reduced oxygen content of the air, their red blood corpuscles are exceptionally numerous.

Alpacas are the most important of the lamoids for wool production. During the period of Incan civilization, the wearing of robes made of alpaca and vicuña wools was reserved for the nobility and royalty. Two breeds of alpaca, the huacaya and the suri, were developed in pre-Columbian times. The wool of the suri is fine and silky and grows long enough to touch the ground if the animal is not sheared. The

wool of the huacaya is shorter and coarser by comparison. The alpaca's wool is remarkably lightweight, strong, lustrous, high in insulation value, and resistant to rain and snow. It is used in parkas, sleeping bags, and fine coat linings. Alpaca fibre is sometimes combined with other fibres to make dress and lightweight suit fabrics and is also woven as a pile fabric used both for coating and as a lining for outerwear. Peru is the leading producer of the wool, with most of it being marketed in the city of Arequipa. The Peruvian government has established a breeding program to improve the quality of alpaca wool and increase its production.

Alpacas are normally sheared every two years, with the suri yielding fine fleeces of about 3 kg (6.5 pounds) per animal, and the huacayas giving coarser fleeces weighing about 2.5 kg. Hair growth in two years is about 30 cm (12 inches) in the huacaya and 60 cm in the suri. Individual fibres within the fleece range from about 20 to 40 cm in length at the time of shearing. Alpacas have a natural life span of 15–20 years.

Alpenrhein River, the part of the Rhine River between the confluence of the Vorder- and Hinterrhein and its entry into Lake Constance. It is 63 miles (102 km) long. From Reichenau to Sargans it flows entirely within Swiss territory; for the next 19 miles (30 km) it forms the border between Switzerland and Liechtenstein; and the last part separates Switzerland from Austria. The river's waters are thick with mud.

Alpes (Roman province): *see* Alps.

Alpes-de-Haute-Provence, formerly (until 1970) BASSES-ALPES, *département*, Provence-Alpes-Côte-d'Azur *région*, southeastern France. It was created in 1790 out of the northern part of Provence and lies wholly within the Provence Alps. It is bounded on the north by Hautes-Alpes *département* and on the east by Italy and Alpes-Maritimes *département*. Alpes-de-Haute-Provence is high and mountainous and is one of the most thinly populated parts of France. Only in the Durance River valley is the elevation below 1,000 feet (300 m), and the mountains near the Italian frontier rise above 10,000 feet (3,000 m). Most of the *département* farther west consists of rugged limestone Pre-Alps. Between mountain-encircled basins, where the Durance River and its tributaries (Ubaye, Bés, Bléone, Asse, and Verdon) open out, are almost impassable gorges dividing the area into separate compartments. The Route Napoléon and the road from Briançon to Nice, which is much frequented by summer tourists, were improved in the 20th century and have helped break down the region's isolation.

In the valleys, cereals and vegetables are grown, and fruit orchards and vineyards are cultivated. Sheep are raised in irrigated meadows. In the extreme south of the *département*, the upper Verdon River has been impounded by the Castillon and Chaudanne dams to provide water for irrigation and hydroelectric power, but the river's middle course is a beautiful gorge frequented by tourists.

Alpes-de-Haute-Provence comprises four *arrondissements*, which centre on Digne-les-Bains (*q.v.*; the departmental capital), Barcelonnette, Castellane, and Forcalquier. The *département* comes under the *académie* (academic district) and court of appeal of Aix. Area 2,674 square miles (6,925 square km). Pop. (1992 est.) 133,800.

Alpes-Maritimes, département, in the region of Provence-Alpes-Côte-d'Azur, southeastern France, bounded northeast by Italy, south by the Mediterranean Sea, and west by the *départements* of Var and Alpes-de-Haute-Provence. It has an area of 1,658 sq mi (4,294 sq km) and is divided into the *arrondissements* of Nice (the *département's* capital) and Grasse. It was formed in 1860 out of the county of Nice (until then a possession of the House of Savoy) with the addition of the districts of Grasse (formerly in Var *département*) and Menton (purchased from the prince of Monaco). Frontier sections ceded by Italy under the terms of the Franco-Italian peace treaty (1947) were also acquired and extended the border northward along the crest of the Maritime Alps. Alpes-Maritimes surrounds the rocky promontory of Monaco, which, with adjoining Monte-Carlo and La Condamine, forms an independent principality.

Most of the *département* consists of limestone mountains (the Maritime Alps east of the Var River and the Provence Alps west of the river), which extend to the coast in rocky headlands, including Cap (cape) Ferrat and Cap d'Antibes. The former shelters the naval base of Villefranche.

The coast, from Cannes in the west to the Italian frontier on the east, has developed as the tourist region known as the French Riviera. Resorts include Nice, Cannes, Menton, Antibes, Monte-Carlo (*qq.v.*), Juan-les-Pins, and many other recently expanded resorts. Grasse, slightly inland, is famous for its perfumes. Agricultural activities, most of which are restricted to the narrow coastal region, include the cultivation of lavender for the perfume industry, vineyards, olive groves, and fruit orchards. Industrialization is poorly developed but includes electronics. Pop. (1982) 881,198.

Alpha and Omega, in Christianity, the first and last letters of the Greek alphabet, used to designate the comprehensiveness of God, implying that God includes all that can be. In the New Testament Revelation to John, the term is used as the self-designation of God and of Christ. The reference in Revelation likely had a Jewish origin, based on such Old Testament passages as Isa. 44:6 ("I am the first and the last"), and Ps. 90:2 ("from everlasting to everlasting thou art God"). In rabbinic literature, the word *emet* ("truth"), composed of the first and last letters of the Hebrew alphabet, is "the seal of God," and in Judaic tradition it carries somewhat the same connotation as Alpha and Omega.

Alpha Aquilae: *see* Altair.

Alpha Centauri, triple star, the faintest component of which, Proxima Centauri, is the closest star to the Sun, at about 4.3 light-years' distance. The two brighter components, about $\frac{1}{10}$ light-year farther from the Sun, revolve around each other with a period of about 80 years, while Proxima circles them with a period probably of millions of years. The brightest component star resembles the Sun in spectral type, diameter, and absolute magnitude. Its apparent visual magnitude is 0.1. The second brightest component, of visual magnitude 1.5, is a redder star. The third component, of 11th magnitude, is a red dwarf star.

As seen from Earth, the system is the third brightest star (after Sirius and Canopus); the red dwarf Proxima is invisible to the unaided eye. Alpha Centauri can be seen only from south of about 40° north latitude.

Alpha Crucis, also called ACRUX, 13th brightest star (excluding the Sun) as seen from Earth. It actually is a binary star; its components have apparent magnitudes of 1.58 and 2.09. Alpha Crucis lies about 400 light-years from the Earth in the constellation Crux (The Southern Cross). The alternate name Acrux is probably a contraction of Alpha Crucis.

Alpha Cygni: *see* Deneb.

alpha decay, type of radioactive disintegration in which some unstable atomic nuclei dissipate excess energy by spontaneously ejecting an alpha particle. Because alpha particles have two positive charges and a mass of four units, their emission from nuclei produces daughter nuclei having a positive nuclear charge or atomic number two units less than their parents and a mass of four units less. Thus polonium-210 (mass number 210 and atomic number 84, *i.e.*, a nucleus with 84 protons) decays by alpha emission to lead-206 (atomic number 82).

The speed and hence the energy of an alpha particle ejected from a given nucleus is a specific property of the parent nucleus and determines the characteristic range or distance the alpha particle travels. Not very penetrating, alpha particles, though ejected at speeds of about one-tenth that of light, have ranges in air of only about one to four inches (corresponding to an energy range of about 4 million to 10 million electron volts).

The principal alpha emitters are found among the elements heavier than bismuth (atomic number 83) and also among the rare-earth elements from neodymium (atomic number 60) to lutetium (atomic number 71). Half-lives for alpha decay range from about a microsecond (10^{-6} second) to about 10^{17} seconds.

Alpha Orionis: *see* Betelgeuse.

alpha particle, positively charged particle, identical to the nucleus of the helium-4 atom, spontaneously emitted by some radioactive substances, consisting of two protons and two neutrons bound together, thus having a mass of four units and a positive charge of two. Discovered and named (1899) by Ernest Rutherford, alpha particles were used by him and co-workers in experiments to probe the structure of atoms in thin metallic foils, work that resulted in the first nuclear conception of the atom (1909-11), and to bombard nitrogen, changing it to oxygen, in the first artificially produced nuclear transmutation (1919). Today, alpha particles are produced for use as projectiles in nuclear research by ionization—*i.e.*, by stripping both electrons from helium atoms—and then accelerating the now positively charged particle to high energies.

Alpha Ursae Minoris: *see* Polaris.

Alpha Virginis: *see* Spica.

alphabet, set of symbols or characters used to represent the sounds of a language. Each character in an alphabet usually represents a simple vowel, a diphthong, or a consonant, rather than a syllable or a group of consonants and vowels. The term alphabet, as used by some, however, also includes the concept of syllabaries.

A brief treatment of alphabets follows. For full treatment, *see* MACROPAEDIA: Writing.

An alphabet is a system of representing the

sounds of a language by a set of clearly understandable and reproducible symbols. This generally involves assigning to the most common sounds their own individual graphemes, or written forms. Although there are numerous cases of duplication—that is, the same sound being represented by two or more graphemes (*e.g.*, the sound of the *g* in *gentle* and the *j* in *jewel*), or a grapheme having no counterpart in its oral form (*e.g.*, the *c* in the spoken *scissors*, the *g* in the spoken *paradigm*)—these exceptions are, in large part, due to the failure of the users of a language to make the changes in spelling that correspond to the changes that have already occurred in spoken usage.

The origin of the alphabet cannot be given with any precision. It is generally agreed, however, that an alphabet known as the North Semitic, originating somewhere in the area around the eastern shores of the Mediterranean in the period between 1700 and 1500 BC, was the first.

A major development took place toward the end of the 2nd millennium BC. The rising political importance of Israel, Phoenicia, and Aram, the commercial importance of the kingdom of Sheba in southwest Arabia, and the growth of what would become the Greek nation provided four branchings: the Canaanite, the Aramaic, the South Semitic (or Sabaean), and the Greek. From the Canaanite and the Aramaic would eventually spring modern Hebrew and Arabic, while the Western alphabets would come down through the Greek, probably by way of the Phoenician.

The spread of the alphabet is as much in debate as its origins. Among the most widely held opinions are these: (1) conquering armies carried their alphabets with them and imposed them, to one degree or another, on their subjects; (2) the widespread trade originating in and around the Fertile Crescent in the Middle East naturally caused a commingling of alphabets as a result of attempts by traders and merchants to achieve a maximum volume of trade with a minimum of confusion; and (3) various religious groups sent out missionaries or other representatives, spreading alphabets in the form of scriptures, homilies, etc.

The Hebrew alphabet as it is still written today came from a form known as the Square Hebrew alphabet, which was itself the product of an Aramaic alphabet learned during the period of the Babylonian Captivity (586?-538 BC). The Square Hebrew script was standardized sometime around the start of the Christian Era and has remained virtually unchanged to this day. The Hebrew alphabet is read from right to left. It has no vowel graphemes, although 4 of the 22 letters are used to indicate long vowels. The remaining vowel sounds are represented by the use of 16 diacritical marks placed above, below, or to the left of a consonant.

The Arabic alphabet, also a descendant of the Aramaic, developed in two main forms: the Kufic and the Naskhi. The Kufic, virtually nonexistent now, was used for stone or metal carvings, coin inscriptions, and the scribing of manuscripts of the Qur'an (Koran). It was distinguished by its heavy, formal letterforms. The Naskhi, from which modern Arabic descends, was a freer form, more suited to handwriting. Like the Hebrew alphabet, the Arabic is virtually vowelless. Only 3 of its 28 letters are used for long vowels, with 14 diacritical marks supplying not only other vowels but distinguishing between consonants and serving as noun and verb modifiers.

All Indian alphabets have their origins in a script called Brāhmī. It is probable that Brāhmī was also a descendant of Aramaic, if not lineally then by example. Another of the original Indian alphabets, Kharoṣṭī, is almost certainly directly evolved from the Aramaic.

From the Brāhmī was developed the Gupta, which further developed into, among others, the Siddhamatrka script. The Siddhamatrka is significant in that out of it came the script used for the writing of Sanskrit, the Devanāgarī. Another of the long-lived scripts, the Devanāgarī has remained unchanged in essentials since the 9th century AD. A noteworthy aspect of these Indian scripts is that, unlike Hebrew or Arabic, these alphabets contain no consonants that are written by themselves. Where a consonant does appear, it is part of a diphthong or else followed by a short *a*.

The Greek alphabet developed around 1000–900 BC, probably from the Phoenician. It branched into a series of eastern and western subdivisions, more notable for their agreement in structure than their differences in detail. Of these, an eastern variant, the Ionic, gradually came to replace the numerous local alphabets until, in 403 BC, it was adopted as the official Athenian alphabet. In the third century BC one of the last modifications of the alphabet took place: the introduction of three accent marks that were to aid foreigners in the correct pronunciation of Greek. Among the most significant offshoots of Greek were the Cyrillic and Etruscan alphabets. The Cyrillic became the script of the Russian, Ukrainian, Bulgarian, Serbian, and Belorussian peoples, while the Etruscan evolved into the Latin alphabet.

Originally, the Romans borrowed 21 of the 26 Etruscan letters. Two more, the *y* and the *z*, were absorbed following Rome's conquest of Greece in the first century BC. The *j* and the *v*, which had previously been written interchangeably with *i* and *u*, respectively, came into being during the Middle Ages. With the addition of the *w* from a Norman source, the Latin alphabet was brought to its present complement of 26.

There have been several attempts at a perfect alphabet which would ideally use one and only one symbol for each sound of a language. The most notable of these efforts resulted in the International Phonetic Alphabet, invented at the close of the 19th century.

alphabet rhyme, mnemonic verse or song used to help children learn an alphabet; such devices appear in almost every alphabetic language. Some of the early English favourites are about 300 years old and have served as models for countless variations. One is a cumulative rhyme to which there is a printed reference as early as 1671. It often appeared in 18th-century chapbooks under the imposing name *The Tragical Death of A, Apple Pie Who was Cut in Pieces and Eat by Twenty-Five Gentlemen with whom All Little People Ought to be Very well acquainted*. It begins:

A was an apple-pie;
B bit it,
C cut it,
D dealt it, etc.

Another, known as "Tom Thumb's Alphabet," enjoyed continuous popularity. The earliest printed record of it is from c. 1712. In its most familiar version, the rhyme begins:

A was an archer, who shot at a frog.
B was a butcher, and had a great dog.

Lines such as "D was a drunkard, and had a red face," "U was a Usurer took Ten per Cent," or "Y was a youth, that did not love school" were later considered to have a harmful effect on children; they were replaced by the widely taught alphabet rhyme of the *New-England Primer*, published by Benjamin Harris (q.v.) in the late 17th century, which combined moral messages with the learning of letters:

In Adam's fall
We sinned all.

A simplified version of English alphabet

rhyme, popular today, is sung to the tune of "Twinkle, Twinkle, Little Star."

Now I've said my ABC's,
Tell me what you think of me.

Alpharabius: see Fārābī, al-

Alphege, SAINT: see Aelfheah, Saint.

Alpheus River, also spelled ALPHEIUS, Modern Greek ALFIÓS POTAMÓS, river, the longest of the Peloponnese (Pelopónnisos), Greece, rising near Dhaviá in central Arcadia, with a course of about 70 miles (110 km). Leaving the plain of Megalópolis in a rugged gorge, above which it is known as the Elisson, the Alpheus turns abruptly northwest and eventually empties into the Ionian Sea. Its main tributaries are the Ládhon and Erímanthos. The hydroelectric Ládhon Dam near the village of Trópaia has created a lake 4 sq miles (10 sq km) in area.

The shallow, gravelly stream receives its name from the ancient river god of the Peloponnese, Alpheus, whose waters were said to pass beneath the Ionian Sea and rise again in the fountain of Arethusa near Syracuse, Sicily. The legend may well have been inspired by the fact that the river disappears several times into the limestone Arcadian mountains and reemerges after flowing some distance underground.

Alphonsine Tables: see Alfonsine Tables.

Alphonsus, prominent crater on the Moon, named for King Alfonso X of Castile. It was the site in 1958 of the first gaseous eruption on the Moon of which a spectrum was recorded. Alphonsus is about 110 km (70 miles) in diameter and lies at about 14° south latitude, 2° west longitude. In November 1958 the Soviet astronomer Nikolay A. Kozyrev, in a groundbreaking discovery, photographed the spectrum of an eruption near the crater's central peak and detected glows of a type characteristic of carbon compounds. Eruptive activity in the crater had been suspected earlier, though not recorded.

alphorn, long horn played by Alpine herdsmen and villagers, sounded for intercommunication and at daily ceremonies and seasonal festivals. It is carved or bored in wood and overwound with birch bark. Some instruments are straight, reaching 12 feet (4 m) in length; since the mid-19th century, especially in Switzerland, the bell may be upcurved. Others, mainly in the eastern Alps, are trumpet-shaped; S-shapes also occur. The compass and

Alphorn blower, near Interlaken, Switzerland
Dallas and John Heaton—Corbis

notes are usually those of a natural (unvalved) French horn in F (about three octaves upward from written F below the bass staff). In the 19th century, playing in trios and quartets was introduced.

The alphorn was mentioned by the Roman historian Tacitus (c. AD 56–120). Similar instruments occur in Scandinavia, Lithuania, the Carpathians, and the Pyrenees.

Alpine, city, seat (1887) of Brewster county, extreme western Texas, U.S., in a high valley (altitude 4,481 feet [1,366 m]), flanked by the Davis Mountains (north) and the Glass Mountains (east), 190 miles (306 km) southeast of El Paso. Founded in 1882 with the arrival of the railroad, it developed as a service centre for a huge ranching area (sheep and Hereford cattle). Alpine's economy was further sustained by the establishment there in 1917 of a normal (teacher training) college, now Sul Ross State University, a member of the Texas State University system. Later the city became known as a mountain resort with dude ranches and ghost mining towns. Davis Mountains State Park, Fort Davis National Historic Site, and McDonald Observatory are a few miles northwest, while Big Bend National Park is 80 miles south. In the 1960s Alpine began to attract generally affluent retirees from urban centres; several small retirement communities now ring the city. Among the area's attractions is the Museum of the Big Bend, located on the Sul Ross campus. Inc. 1888. Pop. (2000) 5,786.

Alpine lakes, the 11 significant European lakes fringing the great mountainous mass of the Alps. Set in magnificent scenery, they are the focus of considerable settlement and a thriving tourist traffic, as well as of great scientific interest.

Most of the Alpine lakes lie in valleys that were formed during the uplift of the mountain chain of the Alps. During the Ice Age of the geologically recent Pleistocene Epoch, less than 2,000,000 years ago, glaciers flowed through these valleys, deepening and excavating the ground, and leaving moraines (deposits of waste material) when they shrank at the end of the glacial period. Water filled up the excavations or was dammed up by the moraines.

The lakes that originated in mountain valleys are long and narrow and are generally very deep. In some cases the glaciers advanced from the Alps into the adjacent plains where they began to diverge fanwise. In such cases the end of the associated lakes broadens or bifurcates.

The lakes are divided into a northern and a southern group by the Alpine watershed running from west to east. The southern group, which lies in an Alpine environment, is made up of Lake Geneva and the Insubrian lakes (Maggiore, Lugano, Como, and Garda). Parts of the northern lakes (Lakes Neuchâtel, Luzern, Zürich, Constance, Chiemsee, Attersee) are situated in the foothill zone of the Alps or even some distance beyond.

Scientific study of Alpine lakes started in Switzerland with F.A. Forel, who studied the stationary oscillations of the water level (seiches) caused by the wind and also made classic observations on the interrelationship between physical and biological processes in lakes. In his work *Le Léman* (1892–1904) he created the term limnology to characterize the comprehensive study of lakes.

In the lakes of the Eastern Alps the phenomenon of the thermocline (zone of rapid decrease of lake temperature below the warm surface stratum in summer) was first studied in the Wörther See (1891). In the same lake, in 1931, it was discovered that there was an absence of total water circulation during the winter in lakes with wind-sheltered sites. These lakes were henceforth characterized as being of meromictic type. The currents caused by the Rhine's flow through Lake Constance

Alpine lakes

Attersee	46	20	171	467	Austrian

were investigated in 1926. The increasing pollution of Lake Zürich brought attention to chemical and biological changes, and, by the late 20th century, a number of institutes were studying the pollution of the Alpine lakes.

The water composition of the Alpine lakes is quite uniform. The chief constituent in solution (up to 96 percent) is bicarbonate associated with calcium or, to a lesser degree, with magnesium. Different amounts of brown humic substances (derived from organic decay) cause colour shifts from blue toward green to olive or brown-green. About 100 years ago almost all the Alpine lakes were poor in plant nutrients, especially in phosphates. During the 20th century many lakes were manured and otherwise polluted by the water wastes from households and hotels. The phosphorus content increased, causing algae known as phytoplankton to multiply, in a process called eutrophication. The extreme growth of phytoplankton under these conditions makes the water turbid and less suitable for bathing. It also intensifies oxygen consumption in the deep layers of the lake as a result of the increased decomposition of dead algae. In extreme cases the spawn of some fish species developing near the bottom can be endangered.

Two methods are used to correct eutrophication. In Switzerland organic substances are removed by mechanical and biological purification, and phosphate is eliminated through additional treatment. In Germany pipelines around the lake borders collect the waste water from catchment areas.

Alpine orogeny, mountain-building event that affected a broad segment of southern Europe and the Mediterranean region during the middle Tertiary Period (the Tertiary began 66.4 million years ago and ended 1.6 million years ago). The Alpine orogeny produced intense metamorphism of preexisting rocks, crumpling of rock strata, and uplift accompanied by both normal and thrust faulting. It was responsible for the elevation of the present Alps, from which the name derives, and for the uplifting of plateaus in the Balkan Peninsula and in Corsica and Sardinia. Volcanic activity in England, France, Iceland, and parts of Italy also occurred during the Alpine orogeny.

Alpine skiing, skiing technique that evolved during the late 19th and early 20th centuries in the mountainous terrain of the Alps in central Europe. Modern Alpine competitive skiing is divided into the so-called speed and technical events, the former comprising downhill skiing (*q.v.*) and the supergiant slalom, or super-G, and the latter including the slalom (*q.v.*) and giant slalom. The speed events are contested in single runs down long, steep, fast courses that feature few and widely spaced turns. The technical events challenge the skier's ability to maneuver over courses marked by closely spaced gates through which both skis must pass; winners are determined by the lowest combined time in two runs on two different courses. The Alpine combined event consists of a downhill and a slalom race, with the winner having a lowest combined time.

The International Ski Federation (FIS), world governing body of the sport, first recognized downhill racing in 1930, and the world championships for men's downhill and slalom events were held in 1931. Women's events were added in 1950. The first Alpine event to be included in the Olympic Winter Games was the combined, which made its debut in 1936 at Garmisch-Partenkirchen, Ger. The 1952 Games in Oslo, Nor., were the site of the first giant slalom Olympic competition, and the supergiant slalom was added at the 1988 Games in Calgary, Alta., Can. That same year the combined event, which had been removed from the roster of Olympic Winter events in the 1940s, returned as an official event. The popularity of Alpine skiing as a recreational activity helped give rise to the sports of freestyle skiing and snowboarding.

For world champions and World Cup winners, see *Sporting Record*. See also *Olympic Games*.

Alpini, Prospero, Alpini also spelled ALPINO (b. Nov. 23, 1553, Marostica, Vicenza [Italy]—d. Nov. 23, 1616, or Feb. 6, 1617, Padua),

Alpini, engraving
By courtesy of the Ashmolean Museum, Oxford

physician and botanist who is credited with the introduction to Europe of coffee and bananas. While a medical adviser to Giorgio Emo, the Venetian consul in Cairo (1580–83), Alpini made an extensive study of Egyptian and Mediterranean flora. He is reputed to have been the first to fertilize date palms artificially.

Alpini was appointed professor of botany at the University of Padua (1593), where he cultivated several species of Oriental plants described in his *De plantis Aegypti liber* (1592; "Book of Egyptian Plants"). Included in this work were the first European botanical accounts of coffee, banana, and a genus of the ginger family (Zingiberaceae) that was later named *Alpinia*.

His account of current Egyptian medical practice, *De medicina Aegyptorum* (1591; "On Egyptian Medicine"), was a valuable addition to medical history. Alpini's study of Egyptian diseases culminated in his widely acclaimed *De praesagienda vita et morte aegrotantium* (1601; *The Presages of Life and Death in Diseases*).

Alps, Latin ALPES, in the Roman Empire, small provinces in the western Alps, occupy-

ing parts of present France, Italy, and Switzerland. The Alpes Maritimae were made a province about 14 BC and included Pedo (Borgo San Dalmazzo in Piedmont) in the Italian foothills and Cemenelum (Cimiez, adjoining Nice). They were administered by a prefect, later a procurator, whose main duty was to protect the road called the Via Julia Augusta.

Adjoining the Alpes Maritimae was the province of the Alpes Cottiae, with its capital at Segusio (Susa in Piedmont) and extending west to Eburodunum (Embrun). King Cottius and his son first ruled it early in the 1st century AD, but a procurator was later appointed.

Farther north was a province in Savoy called variously Alpes Graiae, Atractianae, or Centronicae, with its capital at Forum Claudii Ceutronum (Aime). The entire province was on the transalpine side of the Little St. Bernard (Alpes Graia). All these border areas contained cities that attained Latin rights, a status formally accorded to the whole of the Alpes Maritimae in AD 63.

Alps, great mountain system of south-central Europe, extending about 750 miles (1,200 km) in an arc from the Gulf of Genoa of the Mediterranean Sea in the southwest to Vienna in the northeast and covering more than 80,000 square miles (207,000 square km).

A brief treatment of the Alps follows. For full treatment, see MACROPAEDIA: Europe.

The Alps are divided into a western segment (southeastern France, northwestern Italy), a central segment (north-central Italy, southern Switzerland), and an eastern segment (parts of Germany, Austria, and Slovenia), each of which contains several separate ranges. Geologically belonging to the young folded mountains of the Tertiary Period (66.4 million to 1.6 million years ago), much of the Alps' crystalline regions (notably the Matterhorn at 14,692 feet [4,478 m] above sea level) are characterized by high peaks and nearly vertical slopes, whereas the landscape in limestone regions (the Dolomites of France and Austria) is dominated by huge cliffs and canyons. Elevations average about 6,000 to 8,000 feet (1,800 to 2,400 m), and many peaks rise above 10,000 feet (3,000 m); Mont Blanc (15,771 feet [4,807 m]) is the highest. The Alpine relief has been greatly influenced by glacial erosion, which has created great differences in height between mountain summits and adjacent valleys. The Alps form a divide between the Atlantic, the Mediterranean, and the Black Sea and give rise to several major European rivers, such as the Rhône, the Rhine, and the tributaries of both the Danube and the Po. Annual precipitation decreases from 80 inches (2,000 mm) in the outer ranges to about 20 inches (500 mm) in the inner mountains. Glaciers, covering an area of about 1,500 square miles (3,900 square km), are generally found at elevations above 10,000 feet; the largest (more than 50 square miles [130 square km]) is the Aletsch Glacier in southwestern Switzerland.

Deciduous trees (beech, birch) predominate at lower elevations up to 5,000 feet (1,500 m); coniferous (spruce, pine, larch) in the middle (6,000 feet) zone; and Alpine meadows (grasses, flowers, and shrubs) are found up to 8,000 feet. The higher Alpine zone (above 10,000 feet) is one of rock and permanent snow with no vegetation. Several national parks and reserves in the Alps ensure preservation of native fauna (ibex, chamois, marmot, mountain hare, and golden eagle). The new St. Gotthard Tunnel (1980), at St. Gotthard Pass in southern Switzerland, is the world's longest highway tunnel (10.1 miles [16.3 km]). Grenoble, Fr., Innsbruck, Austria, and Bolzano, Italy, are the major Alpine cities.

Alpujarra rug, handwoven floor covering with pile in loops, made in Spain in the Alpujarras district south of Granada. The construc-

Alpujarra rug from Spain, 1766; in the Hispanic Society of America, New York City

photograph Margaret E. Jackson and Ann Siebert

tion of these rugs makes them more suitable for spreads than for floor use.

The foundation is of linen, and the woolen pile material runs along with the weft, each colour pulled up above the surface in loops as needed in the design. This technique may have been long practiced in the area, but surviving examples probably do not predate the 18th century. The patterns, which can best be described as folk art, are varied, and the colouring is strong.

alpwirtschaft, also called **ALMWIRTSCHAFT**, type of pastoral nomadism that forms a unique economic system in the Alps and involves the migration of livestock between mountain pastures in warm months and lower elevations the remainder of the year. In German, *Alp*, or *Alm*, means mountain pasture, and *Wirtschaft* means domestic economy. Some scholars consider alpwirtschaft to be a limited type of pastoral nomadism subsumed under a broader form known as transhumance, which includes migration within and between regions.

Alpwirtschaft, often called the old mountain economy, developed because many of the mountain valleys, which were occupied by villages and cropland, did not provide sufficient land for livestock grazing. The seasonal migration of livestock to different elevations throughout the year was thus introduced to compensate for the lack of pasture at lower elevations. During the winter the livestock are fed hay and herded between a farmstead in a lower valley and a low mountain farm located at a slightly higher elevation. In the spring, summer, and autumn, the livestock are herded between a lower mountain farm, upland farms, and upland pastures located at the highest elevations. The pastures may be privately owned, shared by neighbours, leased to tenant farmers, or communal. At the lower elevations grazing is supplemented by hay feeding, while pasture at the higher elevations provides ample growth for grazing. At the various elevations of farm and pasture, villages and lodges are located to accommodate the partial or total migration of farmers, herders, and their families.

The location of new industries in many mountain valleys has caused many families

to seek industrial employment while retaining their mountain residence. Thus, fewer families participate in the seasonal migration, and more pastures have been abandoned; many of the less accessible pastures have been converted into resorts.

Als, German **ALSUN**, island (area 121 square miles [312 square km]), in the Little Belt (strait), Sønderjylland *amtskommune* (county commune), Denmark. It is separated from the Sundeved peninsula of southern Jutland by the narrow Als Sound. Fertile clay loams support mixed agriculture, fruit growing, and dairy farming on the island. The earliest known specimen of a northern European boat (c. 300 BC) was discovered there in 1921. Als passed with North Schleswig to Germany in 1864 and was returned to Denmark by plebiscite in 1920. Sønderborg is the principal city, dating from the 12th century; other towns are Nordborg and Augustenborg. Nordborg is the site of one of Denmark's premier industrial companies, Danfoss, which produces heating and refrigerating plants. Pop. (1987 est.) 55,781.

Alsace, *région*, encompassing the northeastern French *départements* of Haut-Rhin and Bas-Rhin and roughly coextensive with the historic region of Alsace. The capital is Strasbourg. The *région* has an area of 3,197 square miles (8,280 square km) and is bounded by the *départements* of Moselle, Meurthe-et-Moselle, and Vosges to the west. The territory of Belfort lies to the southwest; Switzerland borders the *région* to the south, and Germany borders it to the east and northeast.

The area was conquered by the Roman legions of Julius Caesar in the 1st century BC and had been profoundly Romanized by the time of the invasion of the Alemanni in the 5th century AD. The Alemanni, however, were conquered by the Franks under Clovis in 496, and Alsace became a Frankish duchy. Under Merovingian rule the area was Christianized and colonized. Alsace was incorporated in Lotharingia in the mid-9th century and was united with the German territories of the Carolingians by the Treaty of Mersen (870); it remained part of the Holy Roman Empire until the 17th century. During that period its territory was divided into a number of secular and ecclesiastical lordships and municipalities, which remained significant until the French Revolution. The medieval period was also marked by the growing importance of its cities—e.g., Strasbourg, Colmar, and Haguenau, which, with the support of the emperors, gradually freed themselves from their feudal overlords.

Protestantism made important gains in Alsace during the Reformation, and Strasbourg, where the reformer Martin Bucer was especially prominent, became the centre of Alsatian Protestantism. That city's Protestant influence was countered, however, by the res-

The *gouvernement* of Alsace in 1789

olute Roman Catholicism of the Habsburgs, who tried to eradicate heresy in upper Alsace.

French influence began to be felt in Alsace late in the 16th century, during the Wars of Religion. This influence grew during the Thirty Years' War, when the Alsatian cities, caught between the opposing Catholic and Protestant sides and feeling their liberties threatened, appealed to France for help. The Peace of Westphalia (1648) gave France an informal protectorate over Alsace, and full control was established during the reign of Louis XIV, after the French had occupied Strasbourg in 1681.

In the 18th century Alsace enjoyed considerable autonomy under the French crown, and the Alsatians took advantage of their status outside the French customs system to develop a flourishing transit trade. The administrative incorporation of Alsace into France was completed by the French Revolution (1789), when the area was administratively divided into the two *départements* of Haut-Rhin and Bas-Rhin, and its existence as a separate province was ended. The people of Alsace continued to speak a German dialect known as Alsatian, but the use of French spread among the upper classes.

From 1815 to 1870 Alsace actively participated in the French national life. The introduction of universal suffrage (1848) and the building of railways helped to bind France and its eastern frontier province closely together. These links were shattered at the end of the Franco-German War (1870–71), however, when Alsace was detached from France and annexed to the German Empire. For the subsequent history of Alsace, see *Alsace-Lorraine*.

The massif of the Vosges lies in the west and gradually gives way eastward to the plain of Alsace. The region of Sundgau in southern Haut-Rhin belongs to the Jura Mountains. Annual precipitation is relatively low, ranging from 20 to 28 inches (500 to 700 mm).

Alsace is densely populated and has a well-developed agricultural and light-industrial (textile) economy. Approximately one-third of the population is concentrated in the three main cities, Strasbourg, Colmar, and Mulhouse. Outside the Vosges massif the countryside is densely populated, with the result that farms and other landholdings tend to be small and fragmented.

Viticulture thrives on these small farms; Riesling and Gewürztraminer white wines are internationally known and produced for export. Colmar is the principal centre of the wine-growing region, which is concentrated in the hills ringing the Vosges. Industrial crops are widely cultivated and include sugar beets, hops, and tobacco.

The heavier industries are concentrated in Haut-Rhin. The Grand Canal d'Alsace, which channels the Rhine River for hydroelectric power and transportation, has encouraged the development of industries in the plain of Alsace. Manufactures include textiles, electrical appliances, and chemicals. There is a nuclear-power plant at Fessenheim in Haut-Rhin. Pop. (1990) 1,624,372.

Alsace-Lorraine, German **ELSASS-LOTHRINGEN**, area comprising the present French *départements* of Haut-Rhin, Bas-Rhin, and Moselle. Alsace-Lorraine was the name given to the 5,067 square miles (13,123 square km) of territory that was ceded by France to Germany in 1871 after the Franco-German War. This territory was retroceded to France in 1919 after World War I, was ceded again to Germany in 1940 during World War II, and was again retroceded to France in 1945.

Historically, the area was at the centre of Charlemagne's Frankish empire in the 9th century and later became part of the Germanies of the Holy Roman Empire, remaining a German territory under various sovereignties up to the Thirty Years' War. The Peace of

Westphalia (1648) concluding that war gave control of Alsace-Lorraine to France.

Because of its ancient German associations and because of its large German-speaking population, Alsace-Lorraine was incorporated into the German Empire after France's defeat in the Franco-German War (1870-71). The loss of Alsace-Lorraine was a major cause of anti-German feeling in France in the period from 1871 to 1914. France also suffered economically from the loss of Alsace-Lorraine's valuable iron-ore deposits, iron- and steelmaking plants, and other industries to Germany.

Under German rule, Alsace-Lorraine was classified as a *Reichsland* (imperial state) and was denied effective self-government until 1902. Moreover, its population was initially enthusiastic over the new French republic, and German rule remained unpopular for some years among the inhabitants, who continued to protest the German annexation. Thousands of residents who considered themselves French emigrated during this period. By 1905, however, many of Alsace-Lorraine's Roman Catholics had been alienated by the French republic's anticlerical policies, and so they shifted their aspirations toward an autonomous Alsace-Lorraine within the German Empire. Thereafter, especially with the grant of a constitution in 1911, some progress was made toward Germanization in the region.

Alsace-Lorraine was returned to France in 1919 after World War I. The French government's attempts to rapidly assimilate Alsace-Lorraine met with problems, however, especially in France's plans to substitute state-run schools for the region's traditional church schools and in its attempts to suppress German newspapers (German being the written language of 75 percent of the inhabitants). As a consequence, Alsace-Lorraine developed a strong "home rule" movement in the 1920s and unsuccessfully sought autonomy within the French Republic.

Early in World War II, the collapse of France in 1940 was followed by the second German annexation of Alsace-Lorraine, which was again returned to France in 1945. Since then, many of the French prewar governmental policies that had clashed with the region's particularism have been modified, and the autonomist movement has largely disappeared. Linguistically, the German dialect known as Alsatian remains the lingua franca of the region, and both French and German are taught in the schools.

Alster River, tributary of the Elbe River in northern Germany. It rises 4 miles (6 km) southeast of Kaltenkirchen and flows generally south for 30 miles (50 km) to Hamburg, where a dam was built along its course in the Middle Ages. The river then continues to the Elbe in two parallel canals, which mark the division between the newer (since 17th century) part of Hamburg to the west and the older section to the east. A lake formed behind the dam is separated into two parts by fortifications built in the early 17th century to help preserve Hamburg's independence through the Thirty Years' War. The lake's southern portion is called Binnentalster ("Inner Alster") and the northern, Aussenalster ("Outer Alster").

Alston, Walter, in full WALTER EMMONS ALSTON, byname WALT, or SMOKEY, ALSTON (b. Dec. 1, 1911, Venice, Ohio, U.S.—d. Oct. 1, 1984, Oxford, Ohio), professional National League baseball manager whose career with the Los Angeles (formerly Brooklyn) Dodgers was the third longest for managers after Connie Mack and John McGraw.

Alston earned his nickname Smokcy as a pitcher for his high-school team. At Miami University (Oxford, Ohio; B.S. 1935), he was a hard-hitting infielder. He was signed to a con-

tract by the St. Louis Cardinals as a shortstop, played on their minor league teams (1935-40), and managed in the minor leagues (1940-42). In 1944 Alston moved to the Dodgers' organization as a minor league player-manager (1944-47) and manager thereafter until 1953, when he became the Dodgers' manager. As a minor league manager he developed such later Dodger stars as Don Newcombe, Roy Campanella, Carl Erskine, and Junior Gilliam. He had managed every player on his first 25-man roster. As a Dodgers manager he won seven pennants and four of the seven World Series they played in. The 1955 World Series victory was the Dodgers' first.

Alston retired after the 1976 season. He was elected to the Baseball Hall of Fame in 1983.

alstonite, also called BROMLITE, a barium and calcium carbonate mineral, $\text{CaBa}(\text{CO}_3)_2$, with minor amounts of strontium. It is colourless or light gray or pink in appearance and is also transparent or translucent. Its crystal structure is orthorhombic and is identical to that of aragonite, with barium and calcium in nine-fold coordination but ordered within layers; the layers can in turn be arranged in various stacking sequences, resulting in a complex structure. Alstonite is found in association with calcite, barite, and witherite as low-temperature hydrothermal deposits. For detailed physical properties, *see* carbonate mineral (table).

Altai (Russia): *see* Altay.

Altai Mountains, Russian ALTAY, Mongolian ALTAYN NURUU, Chinese (Wade-Giles romanization) A-ERH-T'AI SHAN, mountain system of Central Asia that extends approximately 1,200 miles (2,000 km) in a southeast-northwest direction from the Gobi (desert) to the West Siberian Plain, through Chinese, Mongolian, Russian, and Kazak territory.

A brief treatment of the Altai Mountains follows. For full treatment, *see* MACROPAEDIA: Asia.

The jagged mountain system, whose name is derived from the Turkic-Mongolian *altan*, meaning "golden," divides the waters of such great rivers as the Ob, flowing northward to the Arctic, from those draining into the vast Central Asian interior basin. There are three main branches of the mountain system (northwest to southeast)—the Altai proper and the Mongolian and Gobi Altai. The highest ridges tower more than 13,000 feet (4,000 m), and the Russian peak Belukha rises to 14,783 feet (4,506 m), the highest point in the range.

The Altai and Mongolian Altai ranges are crisscrossed by a network of turbulent rivers which are fed predominantly by melted snow and summer rains. The rivers of the Gobi Altai are shorter, shallower, and often frozen in the winter and dry in the summer. There are more than 3,500 lakes throughout the system, most of structural or glacial origin. The regional climate is severely continental with long, bitterly cold winters and, on the lower slopes, hot summers. Precipitation is high throughout the year on the exposed western mountain ridges but decreases substantially to the east.

There are four fairly distinct vegetation zones in the system: mountain subdesert, mountain steppe, mountain forest, and the alpine regions. About 70 percent of the Altai proper's territory is covered by mountain forests of conifers, birches, and aspens; forests in the Mongolian and Gobi Altai, however, are practically nonexistent.

The Altai are notable for their mining and hydroelectric potential. Large mines and smelters for such nonferrous metals as copper, lead, and zinc have been built in the main range. The development of agriculture and livestock production has resulted in more settled ways

of life, especially among the nomadic herders in the dry southern Mongolian Altai. Health resorts have been developed around the region's mineral springs, and the picturesque mountain peaks and lakes have attracted a growing number of tourists.

Altaic languages, family of languages consisting of three branches—Turkic, Mongolian, and Manchu-Tungus—that show similarities in vocabulary, morphological and syntactic structure, and certain phonological features, and which, on the basis of systematic sound correspondences, are generally considered to be genetically related. There are approximately 50 Altaic languages, with more than 135 million speakers, spread across almost the breadth of Asia from the Arctic Ocean to the latitude of Peking. The most important members of the family are Turkish, Uzbek, Kazak, Uighur, Azerbaijani, Turkmen, and Mongol.

A brief treatment of the Altaic languages follows. For full treatment, *see* MACROPAEDIA: Languages of the World: *Altaic languages*.

The languages of this family are called Altaic because they are thought to have originated in the steppe lands near the Altai Mountains of Central Asia. The peoples of this region were typically nomads who exploited the horse.

Branches of the family. More than 90 percent of all contemporary speakers of Altaic languages speak a Turkic language; of these, Turkish represents the largest number of speakers. The languages of the Turkic branch cover a nearly continuous band from Turkey, Armenia, and Azerbaijan through the Central Asian republics of Kazakstan, Uzbekistan, Turkmenistan, Kyrgyzstan, and Tajikistan, to Sinkiang region in China. Most of these languages are similar to one another; Kyrgyz, Karakalpak, and Kazak in particular are linguistically very close. More distant languages, such as Yakut (spoken in Sakha [Yakutia], northeastern Russia), are not mutually intelligible with the other Turkic languages.

The Mongolian branch of the Altaic family, dominated by the Mongol language, consists of a central group and a number of isolated, peripheral languages. The central group of languages—divided into Western (Oyrat and Kalmyk) and Eastern (Buryat and Mongol) branches—exists chiefly in a compact area consisting of Buryatia republic in Russia, Mongolia, the Inner Mongolia region of China, and the adjacent Chinese provinces of Sinkiang, Tsinghai, and Kansu. The outlying languages—including Moghol (Afghanistan); Daghur (Inner Mongolia, China); and Monguor (or Tu), Bao'an (or Bonan), and Santa (or Tung-hsiang), all of which are spoken in parts of China—are notable for retaining a variety of archaic features.

The Manchu-Tungus branch consists of a number of languages spoken by relatively small populations in widely dispersed communities across most of northernmost Asia. Most of the languages are moribund; Manchu, probably the best-known member of the branch, is virtually extinct. The Southern, or Manchu, group of languages includes Sibo (Xibe), which is closely related to Manchu. The Northern, or Tungus, group includes such languages as Evenk and Even, which are spoken across Siberia and northeastern China.

Linguistic characteristics. In general, Altaic languages are characterized by palatal vowel harmony, in which the vowels within a word may be only front (*i.e.*, vowels formed in the front of the mouth (such as /i, e, ö, ü/) or only non-front (such as /u, a, o, u/) and are not mixed. A common grammatical characteristic is agglutination, in which a fairly large number of affixes may be added to the root; each affix has one meaning or grammatical function and retains its form more or

less unaffected by the morphemes surrounding it. Altaic languages have no prefixes, only suffixes, and postpositions occur in lieu of prepositions. Altaic languages have no grammatical gender, nor agreement of adjectives with nouns. Manchu-Tungus languages, in particular, exhibit a rich system of grammatical cases. The system of verbal morphology in all the languages is quite complex. Basic word order is subject-object-verb (SOV), with modifiers preceding what they modify and specifiers such as quantifiers following the specified. Little or no transformation of basic syntactic structures is permitted; such constructions as questions or statements in the passive voice are formed through the use of markers (whether affixes or auxiliary words), rather than by syntactic transformation. See also Turkic languages; Mongolian languages; Manchu-Tungus languages.

Altair, also called ALPHA AQUILAE, one of the 15 brightest stars, the brightest star in the constellation Aquila, with an apparent visual magnitude of 0.77. Its distance from the Earth is about 16 light-years. It is a hot white star somewhat larger and more massive than the Sun and giving out about 10 times as much light. The name probably derives from Arabic words meaning "the eagle," applied to the constellation.

Altamira, cave famous for its magnificent prehistoric paintings and engravings, situated 30 km (19 miles) west of Santander, in northern Spain. The cave, discovered by a hunter in 1868, was visited in 1875 by Marcelino de Sautuola, a nobleman from Santander, who found animal bones and flint implements there. Sautuola returned in the summer of 1879 and on one visit was accompanied by his little daughter Maria; it was she who first noticed paintings of bulls (actually bison) on the ceiling. Convinced of the antiquity of the paintings and the objects, Sautuola published descriptions of his finds in 1880. Both Spanish and foreign experts, however, dismissed the paintings as forgeries, and not until the first decade of the 20th century were they accepted as genuine.

The Altamira cave is 270 m (890 feet) long. In the vestibule numerous archaeological remains belonging to the Aurignacian (Perigordian), upper Solutrean, and lower or middle Magdalenian periods were found, including ceremonial staves and engraved animal shoulder blades. The great lateral chamber that contains most of the paintings measures 18 by 9 m (60 by 30 feet), the height of the vault varying from 1.15 to 2.65 m. The roof of the chamber is covered with paintings, chiefly of bison, executed in a magnificent, vivid polychrome of red, black, and violet tones. There are also two wild boars, some horses, a hind, and some other figures in a simpler style; in addition, there are eight engraved anthropomorphic figures, various handprints, and hand outlines. The other galleries contain numerous black-painted or engraved figures. In many

Cave painting of a bison, Altamira, Spain

cases, the creator of the designs exploited the natural contours of the rock surface.

Altamura, town, Bari *provincia*, Puglia (Apulia) *regione*, southeastern Italy. Altamura lies on the Murge plateau at 1,552 feet (473 m) above sea level, southwest of Bari. It was founded about 1200 by the Holy Roman emperor Frederick II, who created several new towns in Apulia, to which he attracted Italians, Greeks, and Jews by grants of privileges for their aid in his struggle against the barons. The town is surrounded by the medieval high wall (*alta mura*) from which it takes its name. The Romanesque-style Cathedral of the Assumption, begun in 1232 by Frederick, has been restored several times. The richly carved portal and central rose window in its facade are notable. The Pulo di Altamura, about 4 miles (6 km) away, is a limestone abyss, 1,640 feet (500 m) across and 246 feet (75 m) deep.

Cattle and cereals are the chief products of the district, which also produces almonds and wine. Pop. (1993 est.) mun., 58,673.

Altan, also called ANDA (d. 1583, Mongolia), Mongol khan, or chief, who terrorized China during the 16th century. He converted the Mongols to the reformed, or Dge-lugs-pa (Yellow Hat), sect of Tibetan Buddhism.

Altan became chief of the eastern Mongols in 1543 and thereafter posed a constant threat to the northern borders of China under the Ming dynasty (1368-1644). In 1550 he led his forces across the Great Wall, which marked China's northwest border, and raided the outskirts of the capital at Peking. But he was forced to withdraw back into Mongolia a few days later.

Altan soon began his effort to create a stable system of government in his homeland. Using captured Chinese deserters, he set up a bureaucratic administration in the Chinese style, establishing his capital at Kuku-khoto ("Blue City"), just beyond the Great Wall. He also concluded a peace treaty with the Chinese in 1571, under which Altan was allowed to exchange horses for textiles. The Chinese also honoured him with the title of Shun-i Wang ("Obedient and Righteous Prince").

In 1580 Altan was host to the head of the Dge-lugs-pa. Yellow Hat Buddhism was made the official religion under Altan's rule, and the head of the sect was given the title of Dalai Lama, a title implying spiritual primacy. Altan's own grandson became the new Dalai Lama when the head of the Dge-lugs-pa died. With Mongol military aid, later Dalai Lamas crushed the more established Karma-pa (Red or Black Hat) sect in Tibet and became the spiritual and, finally, temporal rulers of that country.

altar, in religion, a raised structure or place that is used for sacrifice, worship, or prayer.

Altars probably originated when certain localities (a tree, a spring, a rock) came to be regarded as holy or as inhabited by spirits or gods, whose intervention could be solicited by the worshiper. The worshiper's gifts to propitiate or please the gods were placed on an altar nearby. In primitive religions a stone or heap of stones or a mound of earth probably sufficed for this purpose. With the development of the institution of sacrifice in sanctuaries and temples, more elaborate altars were built of stone or brick on which the victim was killed and its blood channeled off or its flesh burned. The altars used in ancient Israel consisted of a rectangular stone with a basin hollowed out on its top. The four corners of the basin terminated in projections; these "horns" came to be regarded as the altar's holiest part, so that anyone clinging to them was immune from molestation. The altars used elsewhere in the Middle East ranged from small upright stands for burning incense to the great rectangular stone altars built in Egyptian temples during the period of the New Kingdom.

The ancient Greeks built altars at the entrances and in the courtyards of their houses, in marketplaces and public buildings, and in sacred groves in the countryside. There were grandiose city altars, on which fire continually burned, and temple altars, which were built in front of the temple rather than within it. The great altar of Zeus at Pergamum (now in the Berlin State Museum) has fine examples of the relief sculptures with which the Greeks decorated their altars. Lofty, imposing altars were used for powerful gods such as Zeus or Athena, while lower altars were thought more suitable for such domestic deities as Vesta and Demeter. Roman altars were very similar to those of the Greeks in their ubiquity, their form, and their relief sculptures.

The earliest Christians used neither temples nor altars in their worship, which was usually conducted in private houses. By the 3rd century AD, however, the table on which the Eucharist was celebrated was regarded as an altar. (The celebration of the Eucharist involves worshipers' consumption of bread and wine that respectively symbolize the body and blood of Jesus Christ.) When the Christians began to build churches, a wooden altar table was placed in the choir or in the apse. These

Israelite horned limestone altar from Megiddo, 10th-9th century BC

By courtesy of the Department of Antiquities, Ministry of Education and Culture, Jerusalem

altars gradually came to be built of stone, and the remains of martyrs were customarily reburied beneath them. In Western churches from as early as the 4th century, the altar was covered by a canopy-like structure, the baldachin, which rested on columns placed around the altar. The altar was further ornamented by an altarpiece (*q.v.*), a screen or wall behind it covered with paintings or sculptures. During the Middle Ages side altars were built in the larger Western churches so that multiple Masses could be celebrated, sometimes simultaneously.

The functions of the altar have remained the same in Christian churches down the centuries. During Mass, it serves as a table to hold a copy of the Bible and the consecrated bread and wine that are distributed to worshipers. One to three cloths cover the altar, and a cross and candles may be placed on or near it. The altar is the focus of the Mass and represents the presence of Christ during the ceremony.

Eastern Orthodox churches have maintained the early Christian custom of regarding the altar as a table. They use only one altar, and it is made of wood. Many Protestant churches have reduced the altar to the status of a table, or communion table. Reformed and Presbyterian churches tend to emphasize its aspect as a table, while the Lutheran and Anglican traditions generally favour an altar.

Altar of Augustan Peace: *see* Ara Pacis.

Altare glass, type of Italian glassware produced in the town of Altare, near Genoa. The Altare glass industry was established in the 11th century by glassmakers from Normandy and developed independently of the much better known glassworks of Venice. During the 15th century the great demand for Venetian glass and, consequently, its profitability led the Venetians to confine glassmakers under pain of death to the island of Murano in an effort to protect their secret techniques. Altare, however, manufactured glassware that was virtually identical to Venetian glass and often sold as such.

The rapid spread of Venetian styles and glass-making techniques can be largely attributed to the craftsmen of Altare. Unlike their Venetian counterparts, the Altare glassmakers were encouraged to work elsewhere. They, together with a few hundred Venetians who escaped from Murano, helped establish glassworks in many European countries. Their work led to the development of an international style known as *façon de Venise (q.v.)* during the 16th and 17th centuries. *See also* Venetian glass.

altarpiece, a work of art that decorates the space above and behind the altar in a Christian church. Painting, relief, and sculpture in the round have all been used in altarpieces, either alone or in combination. These artworks usually depict holy personages, saints, and biblical subjects.

Several technical terms are associated with altarpieces. The predella is a low, decorated strip intended to raise the main part of the altarpiece to a height where it is readily visible from a distance. A diptych is an altarpiece consisting of two painted panels, a triptych has three panels, and a polyptych has four or more panels. A winged altarpiece is one equipped with movable wings that can be opened or closed over a fixed central part, thereby allowing various representations to be exposed to view. The term *reredos* is used for an ornamental screen or partition that is not directly attached to the altar table but is affixed to the wall behind it. The term *retable* simply refers to any ornamental panel behind an altar.

The practice of erecting a structure above and behind the altar and adorning it with artworks extends back at least to the 11th century. Sculpture was the dominant element in the altarpieces of the late Middle Ages, especially in Germany. Altar paintings, by contrast, became common in northern Europe only in the 15th century. Among the most famous of them are "The Adoration of the Lamb," also known as the "Ghent Altarpiece" (1432; Cathedral of Saint-Bavon, Ghent), a polyptych in 12 panels by Hubert and Jan van Eyck; and the Isenheim Altarpiece (1515; Unterlinden Museum, Colmar), a winged altarpiece by Matthias Grünewald. Renaissance Italy, by contrast, favoured altarpieces consisting of single, monumental paintings in simple gilded frames.

The Baroque artists of the 17th century excelled in the creation of large, stagelike altarpieces in which painting, sculpture, and florid ornament are dramatically merged. Gian Lorenzo Bernini's altarpieces are noteworthy examples of this flamboyant tradition, which continued to flourish in Germany, Austria, Spain, and Spanish America well into the 18th century. Religious painting declined elsewhere in Europe during this time, however, and in the 19th century, in keeping with the use of various historical styles in church architecture, the design of altarpieces declined into pure eclecticism. Interesting attempts were made in the 20th century to revive the altarpiece, but the general tendency in modern church design has been to reintroduce the unadorned altar table. *See also* retable.

Altay, formerly (1948–91) GORNO-ALTAY, or (1922–48) OYROT, Altay also spelled ALTAI, republic, southern Russia, in the Altai Mountains. It is bounded on the south by Mongolia and China. It embraces a complex series of ranges and high plateaus, divided by deep valleys and broad basins, that attain a maximum height of 14,783 feet (4,506 m) in Mount Belukha. Steppe vegetation in the basins gives way to dense coniferous forest on the mountain slopes. The republic, centred on the city of Gorno-Altaysk, was formed as an autonomous *oblast* in 1922 for the Mongol Oyrat people for whom it was named until 1948; today about two-thirds of the inhabitants are Russian. The economy is largely agricultural. In the valleys oats, other grains, and vegetables are grown, but the raising of cattle, sheep, goats, horses, and yaks on the mountain and valley pastures is dominant. Fur hunting and timber working are also carried on. Area 35,700 square miles (92,600 square km). Pop. (1995 est.) 200,000.

Altay, also spelled ALTAI, *kray* (region), southwestern Siberia, Russia. Altay *kray* lies in the basin of the upper Ob River and its headstreams, the Biya and Katun. The *kray* borders Kazakstan in the southwest.

Once part of the khanate of Dzungaria, the *kray* was colonized by the Russians from the 18th century. It consists of the rolling plains of the Kulunda Steppe in the west, the Salair Ridge in the east, and the foreland of the Altai Mountains in the southeast. The *kray* has both steppe and forest-steppe vegetation. The steppes are almost entirely under cultivation, with wheat, oats, and corn (maize) the chief crops, together with sunflowers, flax, hemp, and sugar beets. Dairy cattle are also raised. Nonferrous ores—copper, zinc, lead, silver, mercury, barium, tungsten, and gold—are mined, chiefly around Zmeinogorsk and Gornyyak. Light engineering, chemicals, and timber processing are developed in the main cities, notably Barnaul (*q.v.*), the administrative centre. Five rail lines meet at Barnaul, including a link with the Trans-Siberian Railroad to the north. Area 65,300 square miles (169,100 square km). Pop. (1995 est.) 2,695,000.

Altay Mountains (Central Asia): *see* Altai Mountains.

Altdorf, capital of Uri *canton*, central Switzerland. It lies near the confluence of the Reuss River and the Schächen torrent, southeast of

William Tell statue, Altdorf, Switz.

By courtesy of the Swiss National Tourist Office

Lucerne. In the centre of the town a bronze statue of William Tell (1895) marks the place at which, according to tradition, he shot, with his crossbow, an apple from his son's head. The Tell theatre (1925) stages performances of Friedrich Schiller's play *Wilhelm Tell*. Tell is said to have been born at nearby Bürglen. Landmarks in Altdorf include a Capuchin monastery from 1581, a medieval tower, and

the town church and town hall, both rebuilt after 1799. The town is on the St. Gotthard railway line and has cable and rubber works and a federal ammunition factory. The population is mostly Roman Catholic and German-speaking. Pop. (1990) 8,200.

Altdorfer, Albrecht (b. c. 1480—d. Feb. 12, 1538, Regensburg [Germany]), German painter, printmaker, and draftsman who was one of the founders of landscape painting.

"Battle of Alexander at Issus," detail of an oil painting on panel by Albrecht Altdorfer, 1529; in the Alte Pinakothek, Munich

Alte Pinakothek, Munich, photograph, Joachim Blauel/ARTOTHEK

Altdorfer spent most of his life in Regensburg, becoming a citizen in 1505 and in later years serving as official architect of the city and a member of its inner council. He was the guiding spirit of the Danube school of painting. His early figure paintings show a growing preoccupation with landscape, until in "St. George and the Dragon" (1510) the knight is practically overwhelmed by the primeval forest in which he performs his feat. With the "Regensburg Landscape" (c. 1522–25) and other works, Altdorfer painted the first pure landscapes—*i.e.*, landscape scenes containing no human figures whatsoever—since antiquity. His favourite subject was the leafy and impenetrable forests of Germany and Austria. He was also among the first to depict sunset lighting and picturesque ruins in twilight. Several of his altar panels in the Church of St. Florian near Linz, completed in 1518, depicting the Passion of Christ and the martyrdom of St. Sebastian, are night scenes in which he exploited the possibilities of torch light, star light, or twilight with unusual brilliance. Altdorfer's masterpiece, the "Battle of Alexander at Issus" (1529; Alte Pinakothek, Munich), is both a battle scene of incredible detail and a highly dramatic and expressive landscape.

The fantastic element that pervaded Altdorfer's paintings was also prominent in his drawings, most of which were done in black with white highlights on brown or blue-gray paper. His engravings and woodcuts, usually miniatures, are distinguished by their playful inventiveness. Late in his career he used the

new medium of etching to produce a series of landscapes.

alternating current, abbreviation AC, flow of electric charge that periodically reverses; it starts, say, from zero, grows to a maximum, decreases to zero, reverses, reaches a maximum in the opposite direction, returns again to the original value, and repeats this cycle indefinitely. The interval of time between the attainment of a definite value on two successive cycles is called the period; the number of cycles or periods per second is the frequency, and the maximum value in either direction is the amplitude of the alternating current. Low frequencies, such as 50 and 60 cycles per second (hertz), are used for domestic and commercial power, but frequencies around 100,000,000 cycles per second (100 megahertz) are used in television and of several thousand megahertz in radar or microwave communication. *See also* electric current.

alternation of generations, also called METAGENESIS, or HETEROGENESIS, in biology, the alternation of a sexual and an asexual phase in the life cycle of an organism. The two phases, or generations, are often morphologically, and sometimes chromosomally, distinct.

In algae, fungi, mosses, ferns, and seed plants, alternation of generations is common; it is not always easy to observe, however, since one or the other of the generations is often very small, even microscopic. The sexual phase, called the gametophyte, produces gametes, or sex cells; the asexual phase, or sporophyte, produces spores asexually. In terms of chromosomes, the gametophyte has a single (*i.e.*, monoploid, or haploid) set, and the sporophyte has a double (diploid) set.

Among animals, many invertebrates have an alternation of sexual and asexual generations (*e.g.*, protozoans, jellyfish, flatworms), but the alternation of haploid and diploid generations is unknown.

Altgeld, John Peter (b. Dec. 30, 1847, Niederselters, Prussia [now in Germany]—d. March 12, 1902, Joliet, Ill., U.S.), reformist Democratic governor of Illinois (1893–97) known principally for his pardon (June 26, 1893) of German-American anarchists involved in the Haymarket Riot, a labour protest meeting in which seven Chicago policemen were killed at Haymarket Square on May 4, 1886.

Altgeld's German parents immigrated to Ohio, where he was reared. Moving to Chicago in the 1870s, he entered Democratic politics and was elected to the superior court of Cook county (1886–91). Associating himself with the public demand for reform legislation, he won his party's nomination for governor (1892).

The following year he was petitioned by the noted criminal attorney Clarence Darrow and others to grant clemency to three of the men convicted of complicity in the Haymarket Riot. Studying the transcript of the case, Altgeld concluded that the prisoners had not been given a fair trial. His decision evoked an outcry by business and the conservative press, which branded the governor as a friend to anarchists. A year later, Altgeld's protest to President Grover Cleveland against the use of federal troops in the Pullman Strike produced further vitriolic attacks. The furor over these incidents obscured Altgeld's numerous achievements as governor, such as improvements in the penal system and child labour legislation, and led to his defeat for reelection in 1896. Upon leaving office, he returned to the practice of law in partnership with Clarence Darrow.

Althusius, Johannes (Latin), German JOHANNES ALTHAUS (b. 1557, Diedenshausen,

Wittgenstein-Berleberg [now Thionville, France]—d. Aug. 12, 1638, Emden, Holland [now in The Netherlands]). German political theorist who was the intellectual father of modern federalism and an advocate of popular sovereignty.

After philosophical and legal studies in Switzerland, Althusius was a professor at the University of Herborn in Nassau until 1604. His principal work was *Politica methodice digesta atque exemplis sacris et profanis illustrata* (1603), a systematized tract on all forms of human association.

Althusius elaborated five principal types of association, each a combination of the preceding: the family, the voluntary corporation, the local community, the province, and lastly the state. A series of social contracts sustains the system as new groups are brought into existence. Through his discussion of the complex relations between levels and the different types of associational arrangements, he developed a comprehensive theory of federalism as the means of achieving national unity, in which sovereignty, resting in the people through their groups, cannot be transferred because it is essential to the being of the political community.

Althusser, Louis (b. Oct. 16, 1918, Birmandreis, Algeria—d. Oct. 22, 1990, near Paris, France), French philosopher who attained international renown in the 1960s for his attempt to fuse Marxism and structuralism.

Inducted into the French army in 1939, Althusser was captured by German troops in 1940 and spent the remainder of the war in a German prisoner-of-war camp. In 1948 he joined the French Communist Party (PCF); in the same year he was appointed to the faculty of the École Normale Supérieure in Paris, where he taught for nearly three decades.

In his two major works on the philosophy of Karl Marx (1818–83), *For Marx* and *Reading Capital* (both published in 1965), Althusser sought to counter the prevalent interpretation of Marxism as an essentially "humanistic" and "individualist" philosophy in which history is a goal-directed process aimed at the realization and fulfillment of human nature under communism. Althusser asserted that this "Hegelian" interpretation neglected the mature Marx of *Das Kapital* (1867; *Capital*) and other works, in which Marx attempts to develop a new "science" of history focused not on human beings but on the impersonal historical processes of which human beings are the bearers. In a later influential essay, "Ideology and Ideological State Apparatuses" (1969), Althusser argued against traditional interpretations of Marx as an inveterate economic determinist by demonstrating the "quasi-autonomous" role accorded to politics, law, and ideology in Marx's later writings.

Althusser's work proved timely in a number of respects. It complemented efforts by French structuralists to vanquish the "subjectivist" paradigm of existential phenomenology. For Althusser, historical change depended on "objective" factors such as the relationship between forces and relations of production; questions of "consciousness" were always of secondary importance. Althusser also rendered an important service to the struggling PCF. By recasting Marx in the idiom of the dominant intellectual paradigm—structuralism—he was able to convince a new generation of intellectuals in France and abroad of Marx's continued relevance. Ironically, Althusser's efforts were little appreciated by the leadership of the PCF, which tended to regard any sign of intellectual independence among party members as a threat. In 1974 Althusser felt compelled to write an extended self-criticism for his "theoreticist deviation" ("Elements of Self-Criticism").

In November 1980, Althusser suffered a mental breakdown and strangled to death his wife of some 30 years, Hélène Rytman.

Judged unfit to stand trial (he had suffered from manic depression throughout his adult life), he was institutionalized for several years. Althusser's confessional autobiography, *The Future Lasts Forever*, was published posthumously in 1992. (R.B.W.)

Altichiero (b. c. 1330, Zevio, near Verona [Italy]—d. after 1390, Verona?), early Renais-

"Decapitation of St. George," fresco by Altichiero, c. 1384; in the Cappella di S. Giorgio, Padua, Italy

SCALA—Art Resource

sance painter who was the effective founder of the Veronese school and perhaps the most significant northern Italian artist of the 14th century.

Altichiero began his career in Verona, where he remained for a number of years, although nothing is known of his work from this period. In 1370 he moved to Padua, perhaps at the invitation of Duke Francesco I Carrara, for whom he painted fresco portraits (since destroyed) of "famous men" in the Sala dei Giganti and the Palazzo del Capitano. His main surviving works are two fresco cycles done in Padua. The first (completed 1379), which includes a Crucifixion and scenes from the life of St. James, is in the Chapel of San Felice in the Basilica of San Antonio; the other (c. 1384), with scenes from the lives of St. George and other saints, is in the Cappella di San Giorgio nearby. The style of these frescoes follows that of the great Florentine painter Giotto in the use of monumental, vital, and dramatically related figures.

Altichiero's figures relate more realistically than do Giotto's to landscape and architecture, however, and Altichiero shows greater concern with harmonious composition. He sacrifices some of the drama and plastic validity of his scenes to achieve powerful two-dimensional rhythms. Probably in 1390 Altichiero returned to Verona, where he executed a final fresco series in the Church of Santa Anastasia.

altimeter, instrument that measures the altitude of the land surface or any object such as an airplane. The two main types are the pressure altimeter, which is an indicator of atmospheric pressure, and the radio altimeter, which measures the time required for a pulse of radio energy to travel from an object in the atmosphere to the ground and back.

A typical pressure altimeter is illustrated in the Figure. The instrument is enclosed in a case that is connected to the outside of the aircraft by an air pressure inlet at the rear of the housing. Two or more aneroid capsules—*i.e.*, thin corrugated metallic bellows from which air has been exhausted—are positioned near the inlet. These capsules expand when

Pressure altimeter
Encyclopædia Britannica, Inc.

the outside air pressure falls (as in climbing), and contract when the outside air pressure rises (as in descending). By a mechanical arrangement of sector gears, pinion, backlash spring, and crankshaft, the expansion or contraction of the aneroid capsules is converted to the movement of pointers on a dial. The graduated scale dial is marked off in feet (or metres), and a series of pointers may be used to indicate the altitude in units of hundreds, thousands, or ten thousands. The barometric scale dial records the air pressure in millibars (mb). Because atmospheric pressure is measured relative to sea level, a pressure altimeter must be adjusted with a barosetting knob in order to compensate for variations in barometric pressure caused by weather changes.

The radio altimeter measures the distance of an aircraft above the ground rather than above sea level. A cathode-ray tube indicates the time that a pulse of radio energy takes to travel from the aircraft to the ground and back to the aircraft. The altitude is equal to one-half the time multiplied by the speed of the pulse. Radio altimeters are used in automatic navigation and blind-landing systems.

Another device for measuring altitude utilizes the effect of atmospheric pressure on the boiling point of a liquid. The instrument, known as a hypsometer, consists of a cylindrical vessel in which the liquid (usually water) is boiled, surrounded by a jacketed column through which the vapour circulates around a shielded thermometer; the higher the altitude, the lower the pressure and the lower the temperature at which the liquid boils. The boiling temperature is thus inversely proportional to the altitude.

Altiplano, English HIGH PLATEAU, also called PUNA, region of southeastern Peru and western Bolivia. The Altiplano originates northwest of Lake Titicaca in southern Peru and extends about 600 miles (965 km) southeast to the southwestern corner of Bolivia. It is a series of intermontane basins lying at about 12,000 feet (3,650 m) above sea level. Lake Titicaca occupies the northernmost basin; to the south are Lake Poopó and the Coipasa and Uyuni salt flats. The basins are separated by spurs reaching eastward from the Cordillera Occidental of the Andes Mountains. On the eastern side of the Altiplano, however, there is a continuous passageway of gentle gradient extending southward across Bolivia. The Cordillera Oriental of the Andes forms the eastern boundary of the Altiplano.

The dominant vegetation is low trees or shrubs. The region's wildlife originally included the alpaca and the llama, both of which are now bred for wool and serve as pack animals. The southern half of the Altiplano falls within a zone of deficient moisture, while the northern half receives rainfall adequate for the cultivation of crops without irrigation.

Temperatures around the shores of Lake Titicaca are more moderate, and corn (maize)

and wheat can be grown there to an elevation of 12,800 feet (3,900 m). The basin, now the location of urban centres such as Puno and Juliaca, Peru, and La Paz, Bolivia, has been the core of a relatively dense population since ancient times. La Paz, the chief political and commercial city of Bolivia in the Altiplano, is located not far south of Lake Titicaca, at the bottom of a spectacular chasm 1,400 feet (400 m) below the surface of the Altiplano, but still 11,909 feet (3,631 m) above sea level.

Section of the Altiplano in Bolivia
Reifejo

The southern half of the Altiplano is much less hospitable to settlement, although its desolate expanses of desert yield important mineral resources including copper, silver, tungsten, and tin. One of Bolivia's main railway lines runs along the eastern edge of the Altiplano.

Altis, in Greek religion, the sacred grove of Zeus, or the sacred precinct in Olympia, Greece. It was an irregular quadrangular area more than 200 yards (183 m) on each side, and walled except to the north, where it was bounded by the Kronion (hill of Cronus). In it were the temples of Zeus and of Hera, his consort; the principal altars and votive offerings; the small treasuries built by various Dorian states; and the administration buildings for the Olympic Games, which were held nearby. Outside the sacred place were the stadium, hippodrome, baths, and other accommodations for visitors.

altitude and azimuth, in astronomy, gunnery, navigation, and other fields, two coordinates describing the position of an object above the Earth. Altitude in this sense is expressed as angular elevation (up to 90°) above

the horizon. Azimuth, in astronomical measurement, is the number of degrees clockwise from due south (usually) to the object's vertical circle (*i.e.*, a great circle through the object and the zenith). For nonastronomical purposes, azimuth (or bearing) is generally measured clockwise from due north.

altitude sickness, also called MOUNTAIN SICKNESS, acute reaction to a change from sea level or other low-altitude environments to altitudes above 8,000 feet (2,400 m). Although most people gradually recover as they adapt to the low atmospheric pressure of high altitude, some persons experience a reaction that can be severe and, unless they return to low altitude, possibly fatal. Much of the reaction is an exaggeration of normal physiological adaptations to the reduced oxygen available at high altitude, such as breathlessness and racing heartbeat. Other manifestations of altitude sickness include giddiness, headache, swelling of the legs and feet, gastrointestinal upsets, and weakness. These usually occur within six hours to four days after arrival at high altitude and may persist for two to five days.

The more serious type of altitude sickness, pulmonary edema, occurs rarely among newcomers to altitude but more often affects those who have already become acclimated to high elevations and are returning after several days at sea level. In pulmonary edema, fluid accumulates in the lungs and prevents the victim from obtaining sufficient oxygen. The symptoms are quickly reversed when oxygen is given and the individual is evacuated to a lower area.

Altitude sickness was not recognized until 1937, but it has become of increasing concern as improved transportation has made it possible for large numbers of tourists to visit previously inaccessible mountain sites high in the Andes, Himalayas, and Rockies. The exact cause of the illness, although presumably related to low atmospheric pressure and lack of oxygen, is not clear; there is evidence that altered hormone secretion may cause some symptoms.

Altman, Benjamin (b. July 12, 1840, New York, N.Y., U.S.—d. Oct. 7, 1913, New York), American merchant, art collector, and philanthropist who established one of the world's great department stores, B. Altman & Co.

Altman had little formal schooling, but at the age of 25 he opened his first dry-goods store in Manhattan and in 1906 moved it to the uptown section, pioneering the movement of business there. With additions in 1913-14, the store occupied the entire block bounded by Madison and Fifth avenues and 34th and 35th streets. Known for his organizing ability, Altman provided medical service, rest, and other benefits for his employees and set up a foundation for their welfare. The department-store chain Altman founded eventually numbered seven stores in New York and other cities. The chain closed in 1989.

An astute art collector, Altman had extensive holdings of Chinese porcelains, crystals, rugs, and other objects of art. Among his paintings were 13 Rembrandts and canvases by Botticelli, Hans Holbein, and Filippo Lippi. The entire collection was bequeathed to the Metropolitan Museum of Art.

Altman's estate included a substantial gift to the National Academy of Design to encourage American painting.

Altman, Robert (b. Feb. 20, 1925, Kansas City, Mo., U.S.), unconventional and independent American motion-picture director whose works emphasize character and atmosphere over plot in exploring themes of innocence, corruption, and survival. Perhaps his best-known film was his first and

biggest commercial success, the antiwar comedy *M*A*S*H* (1970), set in a Mobile Army Surgical Hospital during the Korean War.

Altman served as a U.S. Army pilot from 1943 to 1947, studied at the University of Missouri for three years, and subsequently directed industrial films. During the late 1950s and '60s he directed for such television series as *Bus Stop* and *Combat*. Altman's first two feature films, *Countdown* (1967) and *That Cold Day in the Park* (1969), met with production difficulties and box-office failure. With *M*A*S*H*, however, Altman won critical accolades and box-office success. The directorial innovations that distinguished the film, most notably the disregard for conventional plot and the use of overlapping strains of dialogue and other sound, subsequently became Altman stocks-in-trade. *Brewster McCloud* of later the same year was an eccentric fantasy on human flight, set in the Houston Astrodome. The critically acclaimed *McCabe and Mrs. Miller* (1971) was called an antiwestern for its irreverent portrait of life in a frontier boomtown.

Altman's next success was *The Long Goodbye* (1973), an updated rendering of a Raymond Chandler detective novel. He stirred both critical and popular debate with the 1976 film *Nashville*, a sprawling, kaleidoscopic view of a political campaign set against the backdrop of the country-music industry. Some critics praised the film as a vivid allegory of American life, while others found it overambitious and muddled.

Altman maintained a prodigious directorial output, but most of his films after *Nashville* were critical or financial failures. Among the more interesting of them are *Three Women* (1977), *A Wedding* (1978), and several film adaptations of contemporary plays, notably *Come Back to the 5 & Dime, Jimmy Dean, Jimmy Dean* (1982). Altman made his third comeback with *The Player* (1992), a black comedy about a motion-picture studio executive who murders a writer. He followed up the success of this scathing satire of Hollywood with *Short Cuts* (1993), a pessimistic look at contemporary American society.

Altman, Sidney (b. May 7, 1939, Montreal, Que., Can.), Canadian-American molecular biologist who, with Thomas R. Cech, received the 1989 Nobel Prize for Chemistry.

Altman attended the Massachusetts Institute of Technology (B.S., 1960, in physics) and the University of Colorado (Ph.D., 1967, in biophysics). He was a molecular biology fellow at Harvard University (1967-69) and at the University of Cambridge (1969-70) before joining the biology faculty at Yale University in 1971. He became a full professor at Yale in 1980, was the department chairman from 1983 to 1985, and served as dean of the undergraduate Yale College from 1985 to 1989. He took U.S. citizenship in 1984 but concurrently retained his Canadian citizenship.

Working independently, Altman and Cech discovered a new role for RNA, or ribonucleic acid. The old belief was that enzymatic activity—the triggering and acceleration of vital chemical reactions within living cells—was the exclusive domain of protein molecules. Altman's and Cech's revolutionary discovery was that RNA, traditionally thought to be simply a passive carrier of genetic codes between different parts of the living cell, could also take on active enzymatic functions. This new knowledge opened up new fields of scientific research and biotechnology and caused scientists to rethink old theories of how cells function.

alto (Italian: "high"), in vocal music the register approximately between the F below middle C to the second D above—the second highest part in four-part music. The word *alto*

originally referred to the highest male voice, singing falsetto (see countertenor).

Alto derives from the term *contratenor altus*, which in Renaissance music referred to the part immediately above the tenor part. Female alto voices are often called *contralto*. The term *alto* is also used for musical instruments having a more or less comparable range—e.g., alto saxophone, alto clarinet, alto flute. The meaning of *alto* in French is "tenor violin" or "tenor saxhorn"—a pitfall for translators; *contralte* in French means the English "alto."

alto horn: see tenor horn.

Alto Uruguai, Rio (Brazil): see Pelotas River.

Alton, town ("parish"), East Hampshire district, county of Hampshire, Eng. It lies among the downs on the River Wey, about 18 miles (29 km) northeast of Winchester by road. The Church of St. Lawrence is in the Perpendicular style with a Norman tower. Eggar's Grammar School was founded in 1642, and there are many Georgian buildings. William Curtis, the botanist, was born at Alton in 1746, and the Curtis Museum was founded in 1855. Within the area are the Lord Mayor Treloar Orthopaedic Hospital, the 20th-century abbey of the Order of St. Paul, and the village of Holybourne, where the novelist and biographer Elizabeth Gaskell died in 1865. During 1809-17 the novelist Jane Austen lived at Chawton, 1 mile (1.6 km) south. Hops are grown in the area, and among the chief industries is brewing. Pop. (1981) 14,366; (1991) 16,005.

Alton, city, Madison county, southwestern Illinois, U.S. It is part of the St. Louis, Mo., urban-industrial complex and lies near the confluence of the Mississippi and Missouri rivers.

Named for a son of Colonel Rufus Easton, a St. Louis lawyer who laid out the town-site in 1817, it became a busy river port by the 1830s and still has considerable river traffic. Its industrial growth was stimulated by the availability of raw materials (iron ore, stone, lead, and zinc) and the establishment of oil refineries. Alton's manufactures include glass, paper, plastic, ammunition, hardware, machinery, and steel products. Factories fill the river plain in the lower town, while the residential area lies on the river bluffs, some of which rise to more than 200 feet (60 m). The Southern Illinois University School of Dental Medicine is in Alton. Lewis and Clark Community College was established (1970) on the campus of the former Monticello College (founded 1838) in nearby Godfrey.

A monument commemorates the Abolitionist newspaper editor Elijah P. Lovejoy, who was killed in Alton by a proslavery mob in 1837. Inc. town, 1821; city, 1837. Pop. (1994 est.) 32,953.

Altoona, city, Blair county, central Pennsylvania, U.S. It is situated on the eastern slopes of the Allegheny Front, which separates the Atlantic from the Mississippi valley watersheds. The city lies 45 miles (72 km) by road northeast of Johnstown. It was founded in 1849 by the Pennsylvania Railroad Company as a base for railroad building over the Alleghenies. Its name probably derives from the Cherokee word *allatoona* ("high lands of great worth").

The site, long a communications focus, had been settled since the 1760s, and Fort Roberdau (1778) was established in the vicinity to protect the local lead deposits used by the patriot army during the American Revolution. In 1787 the Frankstown Trail (connecting the Susquehanna and Ohio river systems) was surveyed through the area; a road was built that shortly after 1800 was extended to Pittsburgh (80 miles [130 km] west). During the canal-building boom of the 1830s, the Portage Railroad, using railroad cars to haul barges up a series of inclined planes and down the western

slopes, was developed to span the 36-mile (58-kilometre) divide between the nearby Juniata and Conemaugh rivers.

Altoona's economy is based on diversified industries and railroad shops. Nearby are the 2,375-foot (723-metre) Horseshoe (railroad) Curve (with a central curve of 220°), the Prince Gallitzin State Park, Wopsonnock Mountain (2,580 feet [786 m]), and Forest Zoo. The Altoona branch of Pennsylvania State University was founded in 1929. Inc. borough, 1854; city, 1868. Pop. (1994 est.) city, 52,531; (1995 est.) Altoona MSA, 131,647.

Altranstädt, treaties of, agreements made during the Second, or Great, Northern War (1700-21) by the Swedish king Charles XII with Augustus II, king of Poland and elector of Saxony (Sept. 24, 1706), and with the Holy Roman emperor Joseph I (Sept. 1, 1707).

Shortly after Augustus was crowned king of Poland (Sept. 15, 1697), he formed an alliance with Denmark and Russia against Sweden (autumn 1699) that precipitated the Second Northern War. Charles, however, swiftly defeated the Danish and Russian armies (1700) and then invaded Poland. Insisting that the Poles depose Augustus, he conquered Warsaw and Kraków (1702). In response, some of the gentry in the territory occupied by Sweden formally deposed Augustus and elected as their new king Stanislaw Leszczyński, the palatine of Poznań (July 12, 1704). When Swedish troops subsequently invaded Saxony (autumn 1705), Augustus, who had retreated there, was compelled to accept the first Treaty of Altranstädt, by which he gave up his claim to the Polish throne, acknowledged Stanislaw as his successor, withdrew Saxony from the war against Sweden, and renounced his alliance with Russia. Only after Peter I the Great of Russia inflicted a major defeat upon the Swedish army at the Battle of Poltava (July 8, 1709) was Augustus able to declare his agreement with Charles to be void, return to Poland, and recover the Polish crown.

After Charles's defeat of Augustus in Saxony, the Habsburg emperor Joseph I, who was engaged in a war against France (the War of the Spanish Succession, 1701-14), feared that Sweden would form an alliance with France and successfully attack Vienna. To offset this danger, Joseph signed the second Treaty of Altranstädt with Charles, pledging to grant greater religious freedom to Protestants in Silesia in exchange for Charles's promise not to join France.

altruism, in ethics, a theory of conduct that regards the good of others as the end of moral action. The term (French *altruisme*, derived from Latin *alter*, "other") was coined in the 19th century by Auguste Comte, the founder of Positivism, and adopted generally as a convenient antithesis to egoism. As a theory of conduct, its adequacy depends on an interpretation of "the good." If the term is taken to mean pleasure and the absence of pain, most altruists have agreed that a moral agent has an obligation to further the pleasures and alleviate the pains of other people. The same argument holds if happiness is taken as the end of life. But critics have asked, if no one has a moral obligation to procure his own happiness, why should anyone else have an obligation to procure happiness for him? Other conflicts have arisen between immediate pain and long-range good, especially when the good envisioned by the doer does not coincide with the vision of the beneficiary.

Some British Utilitarians, such as Herbert Spencer and Leslie Stephen, attacked the distinction between self and others that is basic to both altruism and egoism. Such Utilitarians viewed the end of moral activity as the welfare of society, the social organism.

Altyn Tagh: see A-erh-chin Mountains.

alum, any of a group of hydrated double salts, usually consisting of aluminum sulfate, water of hydration, and the sulfate of another element. A whole series of hydrated double salts results from the hydration of the sulfate of a univalent cation (e.g., potassium) and the sulfate of any one of a number of trivalent cations (e.g., aluminum). Aluminum sulfate can thus form alums with sulfates of the univalent cations of potassium, sodium, ammonium, cesium, and other elements and compounds. In similar fashion, sulfates of the trivalent cations of iron, chromium, manganese, cobalt, and other metals may take the place of aluminum sulfate. The most important alums are potassium sulfate, ammonium sulfate, and sodium sulfate. Potassium sulfate, also known as potassium alum or potash alum, has a molecular formula of $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ or as $KAl(SO_4)_2 \cdot 12H_2O$.

Alums can easily be produced by precipitation from an aqueous solution. In producing potassium alum, for example, aluminum sulfate and potassium sulfate are dissolved in water, and then upon evaporation the alum crystallizes out of the solution. A more common production method is to treat bauxite with sulfuric acid and then with potassium sulfate. Ammonium alum is produced by the evaporation of a water solution containing ammonium sulfate and aluminum sulfate. It can also be obtained by treating a mixture of aluminum sulfate and sulfuric acid with ammonia. Alums occur naturally in various minerals.

Most alums have an astringent and acid taste. They are colourless, odourless, and exist as a white crystalline powder. Alums are generally soluble in hot water, and they can be readily precipitated from aqueous solutions to form large octahedral crystals.

Alums have many uses, but they have been partly supplanted by aluminum sulfate itself, which is easily obtainable by treating bauxite ore with sulfuric acid. The commercial uses of alums mainly stem from the hydrolysis of the aluminum ions, which results in the precipitation of aluminum hydroxide. This chemical has various industrial uses. Paper is sized, for example, by depositing aluminum hydroxide in the interstices of the cellulose fibres. Aluminum hydroxide adsorbs suspended particles from water and is thus a useful flocculating agent in water-purification plants. When used as a mordant (binder) in dyeing, it fixes dye to cotton and other fabrics, rendering the dye insoluble. Alums are also used in pickling, in baking powder, in fire extinguishers, and as astringents in medicine.

Alumbrado (Spanish: "Enlightened"), Italian ILLUMINATO, plural ILLUMINATI, a follower of a mystical movement in Spain during the 16th and 17th centuries. Its adherents claimed that the human soul, having attained a certain degree of perfection, was permitted a vision of the divine and entered into direct communication with the Holy Spirit. From this state the soul could neither advance nor regress. Consequently, participation in the liturgy, good works, and observance of the exterior forms of religious life were unnecessary for those who had received the "light." The Alumbrados came primarily from among the reformed Franciscans and the Jesuits, but their doctrines seem to have influenced all classes of people. The extravagant claims made for their visions and revelations caused them to be relentlessly persecuted. The Inquisition issued edicts against them on three occasions (1568, 1574, and 1623).

alumina, synthetically produced aluminum oxide (Al_2O_3), a white or nearly colourless crystalline substance that is used as a starting material for the smelting of aluminum metal. It also serves as the raw material for a broad range of advanced ceramic products and as an active agent in chemical processing.

Alumina is made from bauxite, a naturally occurring ore containing variable amounts of hydrous (water-containing) aluminum oxides. Frec Al_2O_3 occurs in nature as the mineral corundum and its gemstone forms, sapphire and ruby; these can be produced synthetically from alumina and in fact are occasionally referred to as alumina, but the term is more properly limited to the material employed in aluminum metallurgy, industrial ceramics, and chemical processing.

Some alumina is still produced by melting bauxite in an electric furnace, but most is now extracted from bauxite through the Bayer process, which was developed for the aluminum industry in 1888. In the Bayer process bauxite is crushed, mixed in a solution of sodium hydroxide, and seeded with crystals to precipitate aluminum hydroxide. The hydroxide is heated in a kiln in order to drive off the water and produce several grades of granular or powdery alumina, including activated alumina, smelter-grade alumina, and calcined alumina.

Activated alumina is a porous, granular substance that is used as a substrate for catalysts and as an adsorbent for removing water from gases and liquids. Smelter-grade alumina accounts for 90 percent of all alumina produced; it is electrolyzed into aluminum metal. Calcined alumina is made into a variety of ceramic products, including spark-plug insulators, integrated-circuit packages, bone and dental implants, laboratory ware, sandpaper grits and grinding wheels, and refractory linings for industrial furnaces. These products exhibit the properties for which alumina is well known, including low electric conductivity, resistance to chemical attack, high strength, extreme hardness (9 on the Mohs hardness scale, the highest rating being 10), and high melting point (approximately $2,050^\circ C$, or $3,700^\circ F$).

The toughness of alumina can be improved by the addition of zirconia particles or silicon-carbide whiskers, making it suitable for industrial cutting tools. Also, the normally opaque material can be made translucent by adding small amounts of magnesia. Translucent alumina is employed as the gas container in high-pressure sodium-vapour streetlamps.

aluminum, also spelled ALUMINIUM (Al), chemical element, a lightweight, silvery-white metal of main Group IIIa (boron group) of the periodic table. Aluminum is the most abundant metallic element in the Earth's crust and the most widely used nonferrous metal. Because of its chemical activity, aluminum never occurs in the metallic form in nature, but its compounds are present to a greater or lesser extent in almost all rocks, vegetation, and animals. Aluminum is concentrated in the outer 10 miles (16 km) of the Earth's crust, of which it constitutes about 8 percent by weight; it is exceeded in amount only by oxygen and silicon.

Occurrence, uses, and properties. Aluminum occurs in igneous rocks chiefly as aluminosilicates in feldspars, feldspathoids, and micas; in the soil derived from them as clay; and upon further weathering as bauxite and iron-rich laterite. Bauxite, a mixture of hydrated aluminum oxides, is the principal aluminum ore. Crystalline aluminum oxide (emery, corundum), which occurs in a few igneous rocks, is mined as a natural abrasive or in its finer varieties as rubies and sapphires. Aluminum is present in other gemstones, such as topaz, garnet, and chrysoberyl. Of the many other aluminum minerals, alunite and cryolite have some commercial importance.

Crude aluminum was isolated (1825) by Hans Christian Ørsted by reducing aluminum chloride with potassium amalgam. Sir Humphry Davy had prepared (1809) an iron-aluminum alloy by electrolyzing fused alumina (aluminum oxide) and had already named the ele-

ment aluminum; the word later was modified to aluminium in England and some other European countries. A German chemist, Friedrich Wöhler, using potassium metal as the reducing agent, produced aluminum powder (1827) and small globules of the metal (1845) from which he was able to determine some of its properties.

The new metal was introduced to the public (1855) at the Paris Exposition at about the time that it became available (in small amounts at great expense) by the sodium reduction of molten aluminum chloride. When electric power became relatively plentiful and cheap, almost simultaneously Charles Martin Hall in the United States and Paul-Louis-Toussaint Héroult in France discovered (1886) the modern method of commercially producing aluminum: electrolysis of purified alumina (Al_2O_3) dissolved in molten cryolite (Na_3AlF_6). During the 1960s aluminum moved into first place, ahead of copper, in world production of nonferrous metals. For more specific information about the mining, refining, and production of aluminum, see MACROPAEDIA: Industries, Extraction and Processing.

Aluminum is added in small amounts to certain metals to improve their properties for specific uses, as in aluminum bronzes and most magnesium-base alloys; or, for aluminum-base alloys, moderate amounts of other metals and silicon are added to aluminum. The metal and its alloys are used extensively for aircraft construction, building materials, consumer durables (refrigerators, air conditioners, cooking utensils), electrical conductors, and chemical and food-processing equipment.

Pure aluminum (99.996 percent) is quite soft and weak; commercial aluminum (99.0 to 99.6 percent pure) with small amounts of silicon and iron is hard and strong. Ductile and highly malleable, aluminum can be drawn into wire or rolled into thin foil. The metal is only about one-third as dense as iron or copper. Though chemically active, aluminum is nevertheless highly corrosion-resistant because in air a hard, tough oxide film forms on its surface.

Aluminum is an excellent conductor of heat and electricity. Its thermal conductivity is about one-half that of copper; its electrical conductivity, about two-thirds. It crystallizes in the face-centred cubic structure. All natural aluminum is the stable isotope aluminum-27. Metallic aluminum and its oxide and hydroxide are nontoxic.

Aluminum is slowly attacked by most dilute acids and rapidly dissolves in concentrated hydrochloric acid. Concentrated nitric acid, however, can be shipped in aluminum tank cars because it renders the metal passive. Even very pure aluminum is vigorously attacked by alkalis such as sodium and potassium hydroxide to yield hydrogen and the aluminate ion. Because of its great affinity for oxygen, finely divided aluminum, if ignited, will burn in carbon monoxide or carbon dioxide with the formation of aluminum oxide and carbide; but, at temperatures up to red heat, aluminum is inert to sulfur.

Compounds. Ordinarily, aluminum is trivalent. At elevated temperatures, however, a few gaseous monovalent and bivalent compounds have been prepared ($AlCl$, Al_2O , AlO).

A number of aluminum compounds have important industrial applications. Alumina, which occurs in nature as corundum, is also prepared commercially in large quantities for use in the production of aluminum metal and the manufacture of insulators, spark plugs, and various other products. Upon heating, alumina develops a porous structure, which enables it to adsorb water vapour. This form of aluminum oxide, commercially known as activated alumina, is used for drying gases and

certain liquids. It also serves as a carrier for catalysts of various chemical reactions.

Another major compound is aluminum sulfate, a colourless salt obtained by the action of sulfuric acid on hydrated aluminum oxide. The commercial form is a hydrated crystalline solid with the chemical formula $Al_2(SO_4)_3 \cdot xH_2O$. It is used extensively in paper manufacture as a binder for dyes and as a surface filler. Aluminum sulfate combines with the sulfates of univalent metals to form hydrated double sulfates called alums. The most important of such salts is aluminum potassium sulfate, also known as potassium alum or potash alum, $KAl(SO_4)_2 \cdot 12H_2O$. These alums have many applications, especially in the production of medicines, textiles, and paints.

The reaction of gaseous chlorine with molten aluminum metal produces aluminum chloride, $AlCl_3$; the latter is the most commonly used catalyst in Friedel-Crafts reactions—*i.e.*, synthetic organic reactions involved in the preparations of a wide variety of compounds, including aromatic ketones and anthraquinone and its derivatives. Hydrated aluminum chloride, commonly known as aluminum chlorohydrate, $AlCl_3 \cdot H_2O$, is used as a topical antiperspirant or body deodorant, which acts by constricting the pores. It is one of several aluminum salts employed by the cosmetics industry.

Aluminum hydroxide, $Al(OH)_3$, is used to waterproof fabrics and to produce a number of other aluminum compounds, including salts called aluminates that contain the AlO_2^- group. With hydrogen, aluminum forms aluminum hydride, AlH_3 , a polymeric solid from which are derived the tetrahydroaluminates (important reducing agents). Lithium aluminum hydride ($LiAlH_4$), formed by the reaction of aluminum chloride with lithium hydride, is widely used in organic chemistry—*e.g.*, to reduce aldehydes and ketones to primary and secondary alcohols, respectively.

For statistical data on mine production of ore, see mining (table).

aluminum bronze, any of a group of strong, corrosion-resistant alloys of copper containing from 4 to 15 percent aluminum and small amounts of other metals, used to make many machine parts and tools. Because of their golden colour and high tarnish resistance, the alloys are also used for jewelry and in architecture. Their resistance to oxidation at high temperatures and to corrosion, particularly by dilute acids, makes them useful for pickling equipment and other service involving exposure to dilute sulfuric, hydrochloric, and hydrofluoric acids. They have strength comparable to that of mild steel and are used for such machinery as papermaking machines, brush holders and clamps for welding machines in the electrical industry, heavy-duty gear wheels, worm wheels, metal-forming dies, machine guides, nonsparking tools, and nonmagnetic chains and anchors. Aluminum bronzes can be welded by the metallic arc process and can be brazed (soldered with certain alloys) with special fluxes.

Alloys with up to about 8 percent aluminum can be cold-rolled into sheet or drawn into tubes for use in chemical plants and oil refineries for pressure vessels and heat exchangers. Alloys with more than 8 percent of aluminum may also contain iron and manganese; they are capable of limited cold-working but can be hot-rolled, extruded, or forged.

The strongest and most corrosion-resistant of the group contains nickel; it has been used for gas-turbine compressor blades. Alloys containing approximately 10 percent aluminum are fabricated by sand casting and gravity diecasting into strong objects, including ship propellers.

Aluminum Company of America (Alcoa), American corporation founded in 1888 (as the Pittsburgh Reduction Company) and now a leading producer of aluminum. Its operations range from mining bauxite and other ores to smelting and processing aluminum, fabricating aluminum products, and marketing and shipping. It has majority ownership of Alcoa of Australia Limited, a leading producer of aluminum oxide (alumina). It has foreign operations throughout the world. Corporate headquarters are in Pittsburgh.

Pittsburgh Reduction Company was founded by a group of young men that included Charles Martin Hall, who in 1886 had been the first American to succeed in developing a commercially cheap method of smelting aluminum—by electrolysis. In 1891 the company began producing cast products (such as teakettles) and aluminum sheeting, as well as raw aluminum; and in 1899 it acquired its first bauxite mining rights. By 1907, when it reincorporated as the Aluminum Company of America (Alcoa), it had numerous mines, alumina plants, hydroelectric facilities, aluminum smelters and fabricating facilities, and the Alcoa Technical Center (in Pittsburgh) for laboratory research and development.

In 1928 Alcoa created an independent foreign company, Aluminium Limited (*see* Alcan Aluminium Limited), and transferred to it almost all of Alcoa's holdings then outside the United States. In return, Alcoa received the common stock of Aluminium Limited.

Meanwhile, the U.S. government had been turning a critical eye on Alcoa. In 1912, in an antitrust suit, Alcoa agreed to abandon certain monopolistic practices involving restrictive covenants with suppliers. Then, from 1922 to 1930, a Federal Trade Commission investigation brought further accusations of unfair competition and discrimination. Finally, in 1937, the U.S. Department of Justice filed a complaint charging the company with monopolizing interstate commerce in 16 markets and commodities and engaging in conspiracies with foreign producers. The final court decisions in 1951 absolved Alcoa of wrongdoing, but Alcoa's major stockholders were compelled to divest themselves of their common stock in Aluminium Limited.

Alun: *see* Blackwell, John.

alunite, also called ALUM STONE, a widespread rock-forming sulfate mineral that occupies pockets or seams in volcanic rocks such as rhyolites, trachytes, and andesites, where it presumably formed through their chemical reaction with escaping sulfurous vapours. It has

Alunite from Marysvale, Utah

been used as a source of potash (during World War I) and as a source of alumina (during World War II); in Europe it was once used extensively to make potash alum, and it has been mined for this purpose since the 15th century. Large deposits exist near Beregov, Ukraine; Almería, Spain; and Bullah Delah in New South Wales, Australia. For chemical formula and physical properties, *see* sulfate mineral (table).

alunogen, a sulfate mineral formed by sulfate solutions that attack aluminous minerals; alunogen is hydrated aluminum sulfate, formulated $Al_2(SO_4)_3 \cdot 18H_2O$. It typically occurs as an efflorescence or crevice filling in pyrite-containing coal formations, shales, or slates, as well as in the gossan (weathered capping) of sulfide ore deposits and in volcanic fumarole deposits. In older literature, alunogen and other hairlike sulfate minerals were called *Haarsalz* ("hair salts"). For detailed physical properties, *see* sulfate mineral (table).

Alushta, also spelled ALUŠTA, tourist resort, Crimea, Ukraine, on the south coast of the Crimean Peninsula. It is the site of a settlement dating from the 6th century AD; in the 14th century it was a Genoan stronghold. Tourism, based on the fine beach and relatively cool summers, developed in the late 19th century. Pop. (1991 est.) 37,600.

Aluyi (people): *see* Lozi.

Alva, Fernando Álvarez de Toledo y Pimentel, 3^{er} duque de (3rd duke of): *see* Alba, Fernando Álvarez de Toledo y Pimentel, 3^{er} duque de.

Āḷvār, any of a group of South Indian mystics who in the 7th to 10th century wandered from temple to temple singing ecstatic hymns in adoration of the god Vishnu. The songs of the Āḷvārs rank among the world's greatest devotional literature. Among the followers of Śiva, the counterpart of the Āḷvārs were the Nāyaṇārs.

The name Āḷvār means, in the Tamil language in which they sang, "man who has intuitive knowledge of God." Their bhakti (religious devotion) was of an intensely passionate kind; they compared the soul to a woman who yearns for her lord's love. The Āḷvārs are described as falling unconscious in rapture before the image of their lord, and the saint Nammāḷvār, in speaking of the "madness" of religious exaltation, exhorted his fellow mystics to "run, jump, cry, laugh and sing, and let every man witness it."

The hymns of the Āḷvārs were gathered in the 10th century by Nāthamuni, a leader of the Śrīvaiṣṇava sect, who introduced the regular singing of the hymns in Vaiṣṇava temples of South India. The collection is called *Nālāyira Prabandham* ("Collection of 4,000 Songs").

Alvarado, Pedro de (b. c. 1485, Badajoz, Castile [Spain]—d. 1541, in or near Guadalajara, New Spain [now in Mexico]), a conqueror of Mexico and Central America for Spain.

Alvarado went to Santo Domingo in 1510 and in 1518 commanded one of Juan de Grijalva's ships sent from Cuba to explore the Yucatán Peninsula. In February 1519 he accompanied the army, led from Cuba by Hernán Cortés, that was to conquer Mexico. Alvarado was placed in charge of Tenochtitlán (Mexico City), and in 1522 he became the city's first alcalde (mayor or principal magistrate).

In 1523 Alvarado conquered the Quiché and Cakchiquel of Guatemala and in 1524 founded Santiago de los Caballeros de Guatemala (Ciudad Vieja; present Antigua, Guatemala). This town became the first capital of the captaincy general of Guatemala, later including much of Central America, of which Alvarado was governor (1527–31).

In 1534 Alvarado led an unlicensed expedition to Quito, but in 1535 he sold his ships and munitions to Diego de Almagro, one of Francisco Pizarro's captains. He then returned to Guatemala and, in 1537, to Spain, where he was confirmed as governor of Guatemala for seven years and was given a charter to explore Mexico. He arrived in Honduras in 1539 and died while attempting to quell an Indian uprising in central Mexico.

Álvares Pereira, Nuno (Portuguese soldier); see Pereira, Nuno Álvares.

Álvarez, Juan (b. 1790, Concepción de Atoyac, Mex.—d. Aug. 21, 1867, Acapulco), revolutionary leader for more than 40 years, before and after the end of Spanish rule, and provisional president of Mexico in 1855.

A landowner of mestizo ancestry, Alvarez in 1811 joined José María Morelos in an unsuccessful campaign for independence from Spain. He was prominent in Antonio López de Santa Anna's revolt of 1822–23, which overthrew the first ruler of independent Mexico, Agustín de Iturbide.

In 1847 Alvarez fought in the war against the United States. Two years later he became governor of the new state of Guerrero, ostensibly as a liberal. When Santa Anna reestablished his dictatorship in 1853, however, Alvarez accommodated himself to this situation as long as his hegemony in Guerrero was not threatened. In 1854, when Santa Anna tried to secure direct rule over Guerrero, Alvarez started a rebellion at Ayutla. After Santa Anna had gone into exile, Alvarez assumed control of the government and soon resigned in favour

Juan Álvarez, detail of a portrait by L. Garcés, 19th century

By courtesy of the Instituto Nacional de Antropología e Historia, Mexico City

of Ignacio Comonfort, his ally against Santa Anna. The work of Alvarez and Comonfort resulted in the liberal trend known as La Reforma ("The Reform") and in the constitution of 1857.

Alvarez, Luis W(alter) (b. June 13, 1911, San Francisco—d. Sept. 1, 1988, Berkeley, Calif.), American experimental physicist who was awarded the Nobel Prize for Physics in 1968 for work that included the discovery of many resonance particles (subatomic particles having extremely short lifetimes and occurring only in high-energy nuclear collisions).

Alvarez studied physics at the University of Chicago (B.S., 1932; M.S., 1934; Ph.D., 1936). He joined the faculty of the University of California, Berkeley, in 1936, becoming professor of physics in 1945 and professor emeritus in 1978. In 1938 Alvarez discovered that some radioactive elements decay by orbital-electron capture; *i.e.*, an orbital electron merges with its nucleus, producing an element with an atomic number smaller by one. In 1939 he and Felix Bloch made the first measurement of the magnetic moment of the neutron, a characteristic of the strength and direction of its magnetic field.

Alvarez worked on microwave radar research at the Massachusetts Institute of Technology, Cambridge (1940–43), and participated in the

development of the atomic bomb at the Los Alamos Scientific Laboratory, Los Alamos, N.M., in 1944–45. He suggested the technique for detonating the implosion type of atomic bomb. He also participated in the development of microwave beacons, linear radar antennas, the ground-controlled landing approach system, and a method for aerial bombing using radar to locate targets. After World War II Alvarez helped construct the first proton linear accelerator and developed the liquid hydrogen bubble chamber in which subatomic particles and their reactions are detected.

In about 1980 Alvarez helped his son, the geologist Walter Alvarez, publicize Walter's discovery of a worldwide layer of clay that has a high iridium content and which occupies rock strata at the geochronological boundary

Luis Alvarez

By courtesy of the Lawrence Radiation Laboratory, the University of California, Berkeley

between the Mesozoic and Cenozoic eras; *i.e.*, about 66.4 million years ago. They postulated that the iridium had been deposited following the impact on Earth of an asteroid or comet and that the catastrophic climatic effects of this massive impact caused the extinction of the dinosaurs. This widely publicized theory remained controversial, but it stimulated further research into the causes of the demise of the dinosaurs.

Álvarez Quintero, Serafín and Joaquín (respectively b. March 26, 1871, Utrera, Seville, Spain—d. April 12, 1938, Madrid; b. Jan. 20, 1873, Utrera—d. June 14, 1944, Madrid), brothers who collaborated in almost 200 dramas depicting the life, manners, and speech of Andalusia. Their work was among the most popular in Spain during the early 20th century and greatly added to the revival of the Spanish theatre. Their dramas are remarkable for a vivacious and skilled presentation. Among their better-known plays are *Los galeotes* (1900; "The Galley Slaves"), *El amor que pasa* (1904; "The Love That Passes"), and *Malvaloca* (1912), a serious drama that received the prize of the Spanish Royal Academy. Several of their plays were translated into English by Helen and Harley Granville-Barker (1927–32); their complete works were published in *Obras completas*, 7 vol. (1953–54).

Alvear, Marcelo T(orcuato) de (b. Oct. 4, 1868, Buenos Aires—d. March 23, 1942, Buenos Aires), statesman and political leader who served as president of Argentina from 1922 until 1928.

Alvear belonged to a distinguished Argentine family. He was educated at the University of Buenos Aires, where he received a doctor of jurisprudence degree. He was a cofounder in 1890 of the Radical Civic Union (UCR), the political party representing the liberal-democratic viewpoint in Argentina. He took part in revolutions of 1890, 1893, and 1905 that helped to establish liberal democracy in Argentina; he then served as minister of public works in 1911, as a member of Parliament in 1912–17, and as Argentine ambassador to France in 1917–22.

In 1922 Hipólito Irigoyen, the UCR leader and president of Argentina, designated Alvear as his successor. Alvear served as president

until 1928, when he broke with Irigoyen, founded the Antipersonalist Union Party, a splinter group of the UCR, and formed an alliance with many conservatives (members

Alvear

By courtesy of the Organization of American States

of the old oligarchy that opposed the UCR). Despite Alvear's opposition, Irigoyen regained the presidency in elections in 1928. Alvear rejoined the UCR after a conservative-oriented military coup overthrew Irigoyen's government in 1930. He ran for the presidency in 1931, but he was declared ineligible because less than a full term had expired since he left office.

Alvear's publications include *Acción democrática* (1938; *Democratic Action*) and numerous state papers and public documents.

Alvensleben-Erxleben, Gustav, Graf von (count of) (b. Sept. 30, 1803, Eichenbarleben, Prussia [Germany]—d. June 30, 1881, Gernrode, Ger.), Prussian general and adjutant general who was the chief personal adviser to King (later Emperor) William I.

As a member of the Prussian general staff (1847–58), Alvensleben participated in the suppression of the revolution of 1849 in Baden and was named chief of staff for the troops that remained in occupation. In 1854 he held a similar position in the military government of the Rhineland. Promoted to major general in 1858 and adjutant general in 1861, he acquired considerable influence in the military cabinets and personal counsels of William I. Dispatched to St. Petersburg in 1863, Alvensleben negotiated a convention that provided for Prussian-Russian cooperation in the suppression of insurrections in their subject Polish lands. Faced with the concerted opposition of the Western powers, however, this agreement, known as the Alvensleben Convention (1863), was repudiated by the Prussian government and allowed to pass into oblivion. Subsequently appointed lieutenant general (1863) and general of the infantry (1868), Alvensleben saw service in the Franco-German war (1870–71) as head of the 3rd Army Corps.

alveolar proteinosis, respiratory disorder caused by the filling of large groups of alveoli with protein and lipid (fat) particles. The alveoli are air sacs, minute structures in the lungs in which the exchange of respiratory gases occurs. The gas molecules must pass through a cellular wall, the surface of which is generally covered by a thin film of fatty material secreted from the alveolar cells. When too many fat materials are released from the alveolar cells, or when the cells die in large numbers and fragment into the alveolar cavity, gas exchange is greatly hindered and the symptoms of alveolar proteinosis occur.

The disease manifests itself in laboured breathing, often accompanied by pain, coughing, and a yellow sputum (mucus discharge). There may also be general fatigue and weight loss. The skin becomes tinged with blue in the

most serious cases, an indication that blood is not being adequately oxygenated or rid of carbon dioxide. X rays most frequently show swelling and excess fluids in the lungs.

The precipitating cause of the disease is unknown. Persons affected are usually between 20 and 50 years of age. The disease can exist without causing symptoms for considerable periods, and spontaneous improvement has been known to occur; it is sometimes fatal, but rarely so, if treated. Treatment involves the use of enzymes that dissolve the protein and fat substances, along with rinsing out of the lungs (lavage). One lung at a time is rinsed with a saltwater solution introduced through the windpipe. The fluids drawn back out of the lungs have been found to have a high content of fat. Sometimes the lesions totally clear up after this procedure.

Älvsborg, län (county), southwestern Sweden. Älvsborg is bounded by Norway, Lake Vänern, and the län of Göteborg och Bohus, Halland, Jönköping, Skaraborg, and Värmland. It comprises the traditional *landskap* (province) of Dalsland and part of that of Västergötland. The most important river in Älvsborg is the Göta River, the falls and rapids of which produce hydroelectric power. The county has poor soils and remains largely forested, but wheat, rye, and oats are grown, and cattle raising and dairying are important. The main base of the economy is industry, centred at Borås. A major hydroelectric power station, locks, and locomotive works are located at Trollhättan. Vänersborg is the capital. Area 4,400 square miles (11,395 square km). Pop. (1995 est.) 449,767.

Alwar, also spelled ALWUR, city, northeastern Rājasthān state, northwestern India. The city is surrounded by a wall and moat and is dominated by a fort on a conical hill against a backdrop of a range of hills. Alwar was made the capital of Alwar princely state in 1775; it contains the 14th-century tomb of

The palace and lake at Alwar, Rājasthān, India
Christine Gascoigne

Tarang Sultān (the brother of Firūz Shāh) and several ancient mosques. The palace, which adjoins a picturesque lake, contains a museum that houses a library of Hindī, Sanskrit, and Persian manuscripts and a collection of Rājasthāni and Mughal miniature paintings. Alwar is an agricultural mart and a transportation centre. Its major industries include cloth weaving, oilseed and flour milling, and the manufacture of paint, varnish, and pottery. There are colleges affiliated with the University of Rājasthān. Pop. (1991) 205,086.

Alyattes (d. c. 560 BC), king of Lydia, in west-central Anatolia (reigned c. 610–c. 560 BC), whose conquest created the powerful but short-lived Lydian empire.

Soon after succeeding his father, King Sa-

dyattes, Alyattes started five consecutive years of raids that devastated the farmland around the Greek city of Miletus on the southwestern coast of Anatolia. He moved eastward, battling the Medes for five years, until an eclipse of the Sun brought an end to the fighting. Alyattes also fought with the Carians to the south, whom he conquered, and with the nomadic Cimmerians to the east, whom he drove from western Anatolia. He went on to capture and demolish most of the Greek city of Smyrna (on the west coast of Anatolia; now Izmir, Tur.). He was succeeded by his son Croesus, whose wealth became legendary.

Alyattes' tomb, which was described by Herodotus, can still be seen in west-central Anatolia about 7 miles (11 km) north of the ruins of the Lydian capital of Sardis.

Alyn and Deeside, district, Clwyd county, northeastern Wales. The district, created in 1974, covers an area of rolling lowlands and hills and extends from the River Dee south and west toward the Clwydian Hills. It borders the districts of Delyn to the north, Wrexham Maelor to the south, and Glyndwr to the west and the English districts of Ellesmere Port and Chester to the east.

The region has been an important gateway between England and Wales since the Roman occupation of Britain. During the conquest of Wales (1277–83) by Edward I of England, the castle at Caergwrle, in what is now southern Alyn and Deeside, was given by the king to his queen, Eleanor of Castile. The original Hawarden Castle, in central Alyn and Deeside, was an important English stronghold in the Welsh Marches (border country) during the years following the Edwardian conquest and was subjected to numerous Welsh attacks.

As a result of the exploitation of rich coal deposits in the 19th century, a highly industrialized area developed on the banks of the River Dee. Since the 1970s a number of key factories have closed, notably the huge Shotton steelworks. Hawarden is the administrative seat of the district. Area 59 square miles (154 square km). Pop. (1991 prelim.) 71,700.

Alypius (fl. 3rd or 4th century AD, Alexandria, Egypt), writer on music whose *Eisagōgē mousikē* (*Introduction to Music*) contains a comprehensive summary of the complex system of Greek scales and their transpositions and includes tables of their method of notation. The treatise was published in 1616 by I. Meursius and in 1652, with the tables of notation, by M. Meibom. The authoritative edition is by K. von Jan in *Musici scriptores Graeci* (1895–99).

Alyssum, genus containing the plants known as basket-of-gold and sweet alyssum (*qq.v.*).

Alytus, also spelled ALITUS, German and Polish OLITA, city, southern Lithuania. It lies along the Neman (Lithuanian: Nemunas) River, 37 miles (60 km) south of Kaunas. The city dates from the 14th century. In the 20th century it developed as an industrial centre, with factories producing refrigerators, chemical products, linen, and clothing. Alytus is a rail terminus and road junction and has an agricultural college. Pop. (1994 est.) 77,400.

Alzheimer's disease, degenerative brain disorder that develops in mid- to late adult life and results in a progressive and irreversible decline in memory and various other cognitive functions. The disease is marked by the destruction of nerve cells and neural connections in the cerebral cortex of the brain and by a significant loss of brain mass.

Alzheimer's disease is the most common form of dementia (*q.v.*). The disease develops differently among individuals, and this suggests that more than one pathologic process may lead to the same outcome. Typically, the first symptom to appear is forgetfulness, as short-term memory and immediate recall become

impaired. As the disease progresses, memory loss becomes more severe and the person's language, perceptual, and motor skills deteriorate. Mood becomes unstable, and the person tends to become irritable and more sensitive to stress and may become intermittently angry, anxious, or depressed. In advanced stages, the individual becomes unresponsive and loses mobility and control of body functions; death ensues after a disease course lasting from 2 to 20 years but typically taking 5 to 10 years.

About 10 percent of those who develop the disease are younger than 60 years of age. These cases, referred to as early-onset familial Alzheimer's disease, result from an inherited genetic mutation. The majority of cases of Alzheimer's disease, however, develop after age 60 (late onset); they usually occur sporadically—*i.e.*, in individuals with no family history of the disease—although a genetic factor has been identified that is thought to predispose these individuals to the disorder.

The disease was originally described in 1906 by Alois Alzheimer, a German neuropathologist. In the autopsy of a 55-year-old person who died with severe dementia, he noted the presence in the brain of two abnormalities—neuritic plaques and neurofibrillary tangles. It was principally the identification of neurofibrillary tangles, which had not been described before, that defined the new disease entity. Because Alzheimer's disease was first noted in a relatively young person, it was long regarded as a form of presenile dementia (dementia not associated with advanced age). However, the same brain lesions have been recognized in the brains of many individuals of advanced age who suffer from dementia, and the term Alzheimer's disease is now applied to persons of any age.

Neuritic plaques and neurofibrillary tangles are still the primary features used to diagnose Alzheimer's disease in autopsy. Both structures are thought to interfere in some way with normal cellular functioning. However, it is not known whether the plaques and tangles are a cause or a consequence of the disease. Neuritic plaques, also called senile, dendritic, or amyloid plaques, consist of deteriorating neuronal material surrounding deposits of a sticky protein called amyloid β -protein. This protein is derived from a larger molecule, amyloid precursor protein, which is a normal component of nerve cells. Neurofibrillary tangles are twisted protein fibres located within nerve cells. These fibres consist of a protein, called tau, which normally occurs in neurons. When incorrectly processed, tau molecules clump together, forming tangles.

Other features have been noted in the brains of many persons with Alzheimer's disease. One characteristic is a deficiency in the level of the neurotransmitter acetylcholine. This observation is significant because neurons containing acetylcholine play an important role in memory. Abnormal concentrations of aluminum also have been found to accumulate in neurofibrillary tangles and neuritic plaques, but it is not known whether the element plays a causative role in the disease.

Underlying genetic defects have been identified for the early-onset familial cases of Alzheimer's disease. The first genetic mutation to be discovered—in 1991—was localized to a gene on chromosome 21 that codes for amyloid precursor protein. Defects in this gene are thought to increase the production or deposition of amyloid β -protein, which forms the core of neuritic plaques. This gene, however, is responsible for only 2 to 3 percent of all early-onset familial cases of the disease; the remainder are attributed to two other genes: one on chromosome 14 that accounts for 70 to 80 percent of these cases, and one on chromosome 1 that is responsible for about 20 percent of cases.

Another gene, on chromosome 19, is thought to play a part in the majority of Alzheimer's

cases, the late-onset form. This gene directs production of apolipoprotein E, which is involved in cholesterol transport. There are three forms of this gene—ApoE2, ApoE3, and ApoE4—one of which, ApoE4, is associated with a higher risk of disease.

No cure has been found for Alzheimer's disease. The drug tacrine slightly slows the progression of the disease, but it is not effective in all patients and it can become toxic to the liver. Most treatment aims to control the depression, behavioral problems, and sleeplessness that often accompany the disease.

Alzira, also spelled *ALCIRA*, city, Valencia *provincia*, in the *comunidad autónoma* ("autonomous community") of Valencia, eastern Spain. It lies in the Ribera district, south of the city of Valencia. It originated as the Iberian settlement of Algezira Sucro ("Island of Sucro"), so named because of its insular position between two branches of the Sucro (Júcar) River. It became the Saetabula of the Romans and was called Jazirat Shuvr by the Moors. United to Christian Spain in 1242, it declined after the expulsion of its large Morisco population in the early 17th century. Alzira has a Renaissance city hall (1540; now a national monument) and a Roman bridge over the Júcar. Ruins of the 14th-century monastery of La Murta are nearby. Alzira exports oranges and by-products, manufactures paper goods, and breeds poultry. Pop. (1991 prelim.) 38,558.

Alzon, Emmanuel d', in full *EMMANUEL-MARIE-JOSEPH-AURICE DAUDÉ D'ALZON* (b. Aug. 30, 1810, Le Vigan, France—d. Nov. 21, 1880, Nîmes), French ecclesiastic who founded the order of Augustinians of the Assumption (or Assumptionists).

D'Alzon studied in Paris, in Montpellier, and in Rome, where he was ordained (1834). He was named canon and vicar-general of Nîmes and retained this position until his death. In 1843 he acquired Assumption College in Nîmes, where he founded (1845) the congregation of the Augustinians of the Assumption, dedicated to education and to missionary work; it received papal approval in 1864. To help in this work he also founded a congregation of women, the Oblates of the Assumption. He was sent in 1863 to establish a mission in Constantinople (now Istanbul). In 1871 he started the Alumniates, apostolic schools for the ecclesiastical education of poor boys.

AM (Judaism): *see* anno mundi.

AM, abbreviation of *AMPLITUDE MODULATION*, variation of the amplitude of a carrier wave (commonly a radio wave) in accordance with the characteristics of a signal, such as vocal or musical sound composed of audio-frequency waves. *See* modulation.

AMA: *see* American Medical Association.

Amadeus, name of rulers grouped below by country and indicated by the symbol ●.

Foreign-language equivalents:

French Amédée
Italian Amadeo
Spanish Amadeo

SAVOY

● **Amadeus VI**, byname *AMADEUS THE GREEN COUNT*, Italian *AMEDEO IL CONTE VERDE*, French *AMÉDÉE LE COMTE VERT* (b. 1334, Chambéry, Savoy [now in France]—d. March 1, 1383, Castropignano [Italy]), count of Savoy (1343–83) who significantly extended Savoy's territory and power.

Son of Aimone the Peaceful, count of Savoy, Amadeus ascended the throne at the age of nine. He crossed the Alps in 1348 to put down a revolt of Piedmontese cities and won a victory over rebellious inhabitants of the Valais (east of Geneva) in 1352. In 1355 he mar-

ried Bonne of Bourbon, sister-in-law of the dauphin Charles (later Charles V of France).

Military victories and purchases in the Alpine region in the 1350s increased his holdings, creating the geographic basis for a unified state comprising nearly the whole of the western Alps. He then acquired lands on the Italian side of the mountains.

In 1365 the Holy Roman emperor Charles IV made him imperial vicar. A year later Amadeus responded to Pope Urban V's call for a crusade against the Turks, whom he fought at Gallipoli. Following a campaign against the Bulgarians in the Black Sea area, he restored his cousin, John V Palaeologus, to the Byzantine throne.

Growing prestige made him the arbiter of many of the quarrels between the Italian powers. He acted as mediator between Pisa and Florence in 1364, between the marquesses of Montferrat and the Visconti family from 1375 to 1379, and between Venice and Milan on the one hand and Genoa on the other, negotiating the Peace of Turin (1381). The following year he brought about an accord between the Genoese and the king of Cyprus and was later invited by the Guelf (pro-papal) nobles of Genoa to become doge and take the city under his protection—an empty offer, since the Guelfs were out of power.

In 1382 Amadeus joined Pope Clement VII and the French prince Louis of Anjou in the project of rescuing Queen Joan I of Naples from the rival pope Urban VI and Charles of Durazzo, pretender to the throne of Naples. Launched in June 1382, the expedition was beset by sickness and hunger and bogged down in southern Italy. The following winter Amadeus was stricken with plague and died.

● **Amadeus VII**, byname *AMADEUS THE RED COUNT*, Italian *AMEDEO IL CONTE ROSSO*, French *AMÉDÉE LE COMTE ROUGE* (b. 1360, Chambéry, Savoy [now in France]—d. Nov. 1, 1391, Ripaille), count of Savoy (1383–91), during whose short rule the county of Savoy acquired Nice and other Provençal towns.

Son of Amadeus VI and Bonne of Bourbon, Amadeus married (1377) the daughter of Jean, duc de Berry, brother of the king of France. His father, the "Green Count," wore his customary emerald-green livery at the wedding, and the groom earned his own sobriquet by wearing bright red. Invested with the traditional fief of Savoyard heirs apparent, the seignury of Bresse (west of Geneva), he was soon embroiled in an intermittent six-year war against a vassal, Edward of Beaujeu, who refused him homage. In 1382 he led Savoyard troops against Flemish rebels at the Battle of Rozebeke.

Amadeus died suddenly at the castle of Ripaille, south of Lake Geneva, at the age of 31, apparently as a result of a doctor's blunder.

● **Amadeus VIII**, byname *AMADEUS THE PEACEFUL*, Italian *AMEDEO IL PACIFICO*, French *AMÉDÉE LE PAISIBLE*, also called *POPE FELIX V* (b. 1383, Chambéry, Savoy [now in France]—d. Jan. 7, 1451, Geneva [now in Switzerland]), count (1391–1416) and duke (1416–40) of Savoy, first member of the house of Savoy to assume the title of duke. His 42-year reign saw the extension of his authority from Lake Neuchâtel on the north to the Ligurian coast, and under the title of Felix V he was an antipope for 10 years (1439–49).

The sudden death of Amadeus VII in 1391 left his eight-year-old son under a regency. In 1393 Amadeus married Mary, daughter of Philip the Bold, duke of Burgundy. During the early 1400s he increased the territories of Savoy, laying claim to Geneva in 1401 and buying other nearby lands in 1402 and 1406. In 1416 the Holy Roman emperor Sigismund elevated the county of Savoy to the rank of a duchy.

In 1434, after 42 years on the throne, Amadeus retired to a monastery at Ripaille.

His retirement was only partial, however, and he continued to exercise power, with his son Louis (Ludovico) acting as his lieutenant. During that period Amadeus' daughter Margherita was betrothed to Louis III of Anjou, pretender to the throne of Naples. Louis III died suddenly in 1434, and Amadeus briefly claimed Naples for Margherita but in the end abandoned the kingdom to Alfonso V of Aragon. In 1440 Amadeus abdicated.

One adventure remained to the aging duke: when Pope Eugenius IV broke off relations with the rebellious Council of Basel in 1439, the mutinous prelates elected Amadeus pope under the name of Felix V. Amadeus-Felix resigned 10 years later, under pressure from the kings of France, England, and Sicily, and was a cardinal for his last two years.

SPAIN

● **Amadeus** (b. May 30, 1845, Turin, Piedmont [now in Italy]—d. Jan. 18, 1890, Turin), king of Spain from Nov. 16, 1870, until his abdication on Feb. 11, 1873, after which the first Spanish republic was proclaimed.

The second son of the future King Victor Emmanuel II of Sardinia-Piedmont (later, of Italy), he was originally called Amadeus I, duke of Aosta. His candidacy for the Spanish throne (vacant after the deposition of Isabella II in September 1868) was supported by Juan Prim, the Spanish prime minister, and Francisco Serrano, the regent. It was opposed by adherents of Isabella's son Alfonso de Borbón (later King Alfonso XII) and advocates of a republic. Elected king by the Cortes (parliament), Amadeus arrived in Spain on Dec. 30, 1870, the day on which Prim died from an assassin's attack. Bereft of Prim's help and feebly served by a series of short-lived ministries, Amadeus faced continuous turmoil. Support for Alfonso increased, along with republican agitation, and the Second Carlist War (1872–76) broke out. As soon as circumstances permitted, Amadeus abdicated gracefully and returned to Italy.

Amadeus, Lake, salty mud basin in southwestern Northern Territory, Australia. The lake occupies a shallow trough filled with sediments washed from the MacDonnell (north) and Musgrave (south) ranges. It intermittently contains a few inches of water and at such times may measure as much as 90 miles (145 km) long and 12 miles (20 km) wide, covering some 340 square miles (880 square km). When dry, it is a playa, or salt flat. The explorer Ernest Giles visited the lake in 1872 and named it for Amadeus, then king of Spain. Some cattle, sustained by underground water, are raised in the vicinity, and natural gas is exploited north of the lake. Lake Neale is a similar feature to the northwest.

Amadi, Elechi (b. May 12, 1934, Aluu, near Port Harcourt, Nigeria), novelist and playwright best known for works that explore the role of the supernatural in Nigerian village life.

Amadi, an Ijo (Ijaw) who wrote in English, was educated at Government College, Umuahia, and University College, Ibadan, in physics and mathematics. He served in the Nigerian army, taught, and worked for the Ministry of Information. *Sunset in Biafra* (1973), his only work of nonfiction, recounts his experiences as a soldier and civilian during the Biafran conflict.

Amadi is best known, however, for his historical trilogy about traditional life in rural Nigeria: *The Concubine* (1966), *The Great Ponds* (1969), and *The Slave* (1978). These novels concern human destiny and the extent to which it can be changed; the relationship between people and their gods is the cen-

tral issue explored. Amadi is a keen observer of details of daily life and religious rituals, which he unobtrusively describes in his dramatic stories. Similar emphases are found in his verse play, *Isiburu* (1973), about a champion wrestler who is ultimately defeated by the supernatural power of his enemy. Among his other works is *Pepper Soup and the Road to Ibadan* (1977).

Amadis of Gaul, Spanish AMADÍS DE GAULA, prose romance of chivalry, possibly Portuguese in origin. The first known version of this work, dating from 1508, was written in Spanish by Garcí Ordóñez (or Rodríguez) de Montalvo, who claimed to have "corrected and emended" corrupt originals. Internal evidence suggests that the *Amadis* had been in circulation since the early 14th century or even the late 13th.

In Montalvo's version, Amadis was the most handsome, upright, and valiant of knights. The story of his incredible feats of arms, in which he is never defeated, was interwoven with that of his love for Oriana, daughter of Lisuarte, king of England.

Many characters in the *Amadis* were based on figures from Celtic romance, and the work was, indeed, Arthurian in spirit. It differed, however, from the Arthurian cycle in numerous important respects. Whereas earlier romance had reflected a feudal society, the *Amadis* invested the monarchy with an authority that heralds the advent of absolutism. Amadis himself was more idealized and therefore less human than such earlier heroes as Lancelot and Tristan. He was also far more chaste: French romance had already put a courtly veneer over the disruptive eroticism of the Celtic tales, but, with the *Amadis*, medieval chivalry achieved complete respectability.

The work and its exaltation of new standards of knightly conduct caught the imagination of polite society all over Europe. In France, especially, it became the textbook of chivalresque deportment and epistolary style. Throughout the 16th century, numerous sequels and feeble imitations appeared, the fashion being given its deathblow by parody early in the 17th century in Miguel de Cervantes' novel *Don Quixote* (though Cervantes held the original in high esteem). The first English adaptation of the *Amadis* appeared in 1567; the best English translation is an abridged version by the poet Robert Southey, first published in 1803.

Amado, Jorge (b. Aug. 10, 1912, Ferradas, near Ilhéus, Brazil), novelist whose stories of life in the Brazilian northeast won international acclaim.

Amado grew up on a cacao plantation, Auricidia, and was educated at the Jesuit college and another school in Salvador. He published his first novel at the age of 20. Three of his early works deal with the cacao plantations, emphasizing the exploitation and the misery of the migrant blacks, mulattoes, and poor whites who pick the beans and generally expressing communist solutions to social problems. The best of these, *Terras do sem fim* (1942; *The Violent Land*), about the struggle of rival planters for some cacao groves, has the primitive grandeur of a folk saga.

Amado became a journalist in 1930, and his literary career paralleled a career in radical politics that won him election to the Constituent Assembly as a federal deputy representing the Communist Party of Brazil in 1946. He was imprisoned as early as 1935 and periodically exiled for his leftist activities, and many of his books were banned in Brazil and Portugal. He continued to produce novels with facility, most of them picaresque, ribald tales of Bahian city life, especially that of the racially conglomerate lower classes. *Gabriela*,

cravo e canela (1958; *Gabriela, Clove and Cinnamon*) and *Dona Flor e seus dois maridos* (1966; *Dona Flor and Her Two Husbands*, film, 1978) both preserve Amado's political attitude in their satire. His later works include *Tenda dos milagres* (1969; *Tent of Miracles*), *Tieta do agreste* (1977; *Tieta, the Goat Girl*), *Tocaia grande* (1984; *Show Down*), and *Sun-ço da santa* (1993; *The War of the Saints*).

Amagasaki, city and industrial suburb of the Ōsaka-Kōbe (Hanshin) metropolitan area, Hyōgo ken (prefecture), Honshu, Japan. In the feudal period it was a castle town. During the 20th century it attracted large, modern factories, formerly geared to wartime production, to produce iron and steel goods, electrical machinery, transport vehicles, and chemicals. The main industrial belt lies along the coast, where costly protective dikes have been constructed. The city has superb railroad facilities and canals and strong economic ties with Ōsaka. Extensive withdrawal of groundwater for industrial use has led to serious land subsidence, rendering the city vulnerable to high waves during the typhoon season. Preventive measures include landfill and external water-supply systems. Railroad lines and numerous other facilities were damaged by the Hanshin earthquake of 1995. Pop. (1994 est.) 493,158.

ber of the Hawaiian honeycreeper family, Drepanididae (order Passeriformes). It is 12 cm (5 inches) long, with yellow body, black eye-mark, and rather short, slightly curved bill. It feeds on insects and small fruits in brushland and forest, and it has mewing and trilling calls.

Amakusa Islands, Japanese AMAKUSA-SHOTŌ, archipelago off western Kyushu, Japan, in the Amakusa Sea. Administered by Kumamoto ken (prefecture), it includes about 100 islands, the largest of which are Kami ("Upper") Island and Shimo ("Lower") Island. There is little farming because of the rough, mountainous terrain, and there are few industries, but forestry, orange cultivation, and offshore fishing are actively pursued.

The Amakusa Islands, connected by bridges to mainland Kyushu, Japan
Onon Press—FPG

The Amakusa Islands, linked by five bridges and by ferry services, are part of Unzen-Amakusa National Park. The archipelago was long the gateway for Western culture and was an early centre of Christianity. The largest cities are Hondo and Ushibuka, both on Shimo Island.

Amalaric (d. 531), king of the Visigoths (526–531), son of Alaric I.

Amalaric was a child when his father fell in battle against Clovis, king of the Franks (507). He was carried for safety into Spain, which country, with southern Languedoc and Provence, was thenceforth ruled by his maternal grandfather Theodoric the Great through his vice-regent, an Ostrogothic nobleman named Theudis. On Theodoric's death in 526, Amalaric assumed full royal power in Spain and a part of Languedoc, relinquishing Provence to his cousin Athalaric. He married Clotilda, daughter of Clovis, but his disputes with her, he being an Arian and she a Catholic, brought on a Frankish invasion, in which he lost his life.

Amalasantha, also spelled AMALASUENTHA (b. 498—d. 535, Tuscany [Italy]), daughter of Theodoric the Great, Ostrogothic king of Italy, and queen and regent of the Ostrogoths (526–534).

When her husband died, Amalasantha was left with a son, Athalaric, and a daughter. At Theodoric's death, in 526, Athalaric was 10 years old, and Amalasantha assumed the regency. Her pro-Byzantine policy, her patronage of literature and the arts, and her desire to educate her son as a Roman prince were vigorously opposed by a large segment of the Ostrogoth nobility. Hence, she moved even closer to her Byzantine suzerain, arranging with the emperor Justinian that if she were removed from power she would transfer herself and the whole Ostrogothic treasure to Constantinople. After successfully quelling a plot against her in 533, she put to death three suspected Ostrogothic nobles.

Upon Athalaric's death in October 534, Amalasantha shared the throne with her cousin Theodahad (*q.v.*), hoping to give him the title of king while retaining actual power herself. Theodahad, however, influenced by forces increasingly hostile to Amalasantha's policies, banished her to an island in the Tuscan lake of Bolsena, where she was strangled in her bath by relatives of the nobles killed after the plot of 533.

Amalekite, member of an ancient nomadic tribe, or collection of tribes, described in the Old Testament as relentless enemies of Israel, even though they were closely related to Ephraim, one of the 12 tribes of Israel. The district over which they ranged was south of Judah and probably extended into northern Arabia. The Amalekites harassed the Hebrews during their Exodus from Egypt and attacked them at Rephidim near Mount Sinai,

where they were defeated by Joshua. They were among the nomadic raiders defeated by Gideon and were condemned to annihilation by Samuel. Their final defeat occurred in the time of Hezekiah.

Amalfi, town and archiepiscopal see, Salerno *provincia*, Campania *regione*, southern Italy. It lies in the ravine of the Mulini Valley, along the Gulf of Salerno, southeast of Naples. Although it was known in the 4th century, Amalfi was of little importance until the mid-6th century under the Byzantines. As one of the first Italian maritime republics in the 9th century, it rivaled Pisa, Genoa, Venice, and Gaeta as a naval power in trade with the East.

Amalfi, with the Cathedral of Sant'Andrea illuminated (lower left)

Amendola/Franca Speranza

Subdued and annexed by King Roger II of Sicily in 1131, it was sacked by the Pisans in 1135 and 1137 and rapidly declined in importance, although its maritime code, the Tavola Amalfitana ("Table of Amalfi"), was recognized in the Mediterranean until 1570. The town is dominated by the Cathedral of Sant'Andrea (begun in the 9th century, often restored), which has magnificent bronze doors, executed at Constantinople about 1065, and a campanile (1180-1276). Also notable are the Chiostro del Paradiso (cloister; 1266-68), adjacent to the cathedral; high on a cliff is the former Capuchin convent (founded 1212), which is now a hotel.

Amalfi is now one of the important tourist resorts in Italy, noted for its mild climate and splendid coastal scenery, with high precipices and a background of picturesque hillside houses. The local cultivation of lemons is known throughout Italy. Pop. (1993 est.) mun., 5,619.

Amalfi, Ottavio Piccolomini, Duke (duca d'): see Piccolomini-Pieri, Ottavio.

amalgam, alloy of mercury and one or more other metals. Amalgams are crystalline in structure, except for those with a high mercury content, which are liquid. Known since early times, they were mentioned by Pliny the Elder in the 1st century AD. In dentistry, an amalgam of silver and tin, with minor amounts of copper and zinc, is used to fill teeth.

A sodium amalgam is formed during the manufacture of chlorine and sodium hydroxide by the electrolysis of brine in cells wherein a stream of mercury constitutes the negative electrode. Reaction of the amalgam with water produces a solution of sodium hydroxide and regenerates the mercury for reuse.

Fine particles of silver and gold can be recovered by agitating their ores with mercury and allowing the resultant pasty or liquid amalgam

to settle. By distillation of the amalgam, the mercury is reclaimed, and the precious metals are isolated as a residue.

Amalgams of silver, gold, and palladium are known in nature. Moschellandsbergite, silver amalgam, is found at Moschellandsberg, Ger.; Sala, Swed.; and Isère, France. Gold amalgam occurs in California, U.S., Colombia, and Borneo. For detailed physical properties of naturally occurring amalgams, see native element (table).

Amalgamated Clothing and Textile Workers Union (ACTWU), former union of garment and apparel workers in the United States and Canada. It was formed in 1976 by the merger of the Amalgamated Clothing Workers of America (ACWA), a large union representing workers in the men's clothing industry, with the Textile Workers Union of America, a smaller union founded in 1939. The ACWA was originally formed when militant elements within the United Garment Workers, a relatively conservative union, broke away in 1914 to form their own union under the leadership of Sidney Hillman (*q.v.*). He became president of the new union and held that office until his death in 1946. Under Hillman's leadership the ACWA became the most important and successful of the clothing unions. It secured great improvements and benefits for its members, including cooperative housing, banks, and insurance programs. In 1933 the ACWA was admitted into the American Federation of Labor, but it withdrew to become a founding member of the Congress of Industrial Organizations (CIO) in 1935.

The merger of the ACWA with the Textile Workers Union of America in 1976 produced a new union, the ACTWU, which had a membership of about 500,000. Over the next two decades the ACTWU's membership shrank along with employment in the American apparel industry, and in 1995 the ACTWU merged with the International Ladies' Garment Workers' Union to form the Union of Needletrades, Industrial and Textile Employees (UNITE), with a total membership of about 350,000.

Amalgamated Engineering and Electrical Union (AEEU), the leading trade union in the manufacturing sector of the United Kingdom. It arose out of the merger of the Amalgamated Engineering Union (AEU) with the Electrical, Electronic, Telecommunication and Plumbing Union (EETPU) in 1992.

Of the two organizations, the AEU was much the larger and had a much longer history, though both originated as unions of skilled craftsmen and only later opened their ranks to all employees within their respective industries. The AEU's forerunner was the Amalgamated Society of Engineers, which was formed in 1851 through the merger of several unions, the largest of which dated back to 1826. The ASE was the most powerful and prestigious craft union of its time and continued to flourish until after World War I, when it merged with nine other unions to form the AEU. As crafts gave way to mass production, the AEU began to organize on industrial lines, opening its membership to all manual-engineering workers in the 1920s. Despite a 40-percent membership decline in the 1980s, the AEU was still the second largest union of metalworkers in Europe at the time of its merger with the EETPU, having about 700,000 members.

The latter union, founded in 1889 as the Electrical Trades Union, was renamed EETPU on its merger with the Plumbing Trades Union in 1968. The merger of the AEU with the EETPU in 1992 resulted in a union of about one million members and was undertaken largely for defensive reasons, to better cope with the radically altered industrial climate of Britain in the late 20th century.

Amalienborg, architectural complex in Copenhagen, Den., built during the reign (1746-66) of King Frederick V and comprising the four buildings of the Amalienborg royal palace and the octagonal courtyard surrounded by them. The complex was designed and constructed by the Danish architect Nicolai Eigtved, who also designed numerous other buildings in the surrounding district. At the centre of the court stands an equestrian statue of Frederick V by the French sculptor J.F.J. Saly. The Amalienborg complex is considered to be one of the finest examples of Rococo-style architecture in Europe. It still serves as the chief residence of the Danish royal family.

Amalric I, French AMAURY, or AMAURI (d. July 11, 1174), king of Jerusalem from 1163 to 1174, a strong ruler, who protected the rights of vassals and helped prevent Muslim unity around the Holy Lands.

Amalric, the son of King Fulk of Jerusalem, had been count of Jaffa and Ascalon before succeeding his elder brother Baldwin III on the throne in 1163. He was forced first to annul his marriage to Agnes of Courtenay because she was his third cousin (rights of legitimacy and inheritance, however, were granted to his son Baldwin and a daughter by Agnes). Insisting that a case of an unjustly dismissed vassal be heard, he passed a law giving vassals the right to appeal against treatment by their lords to the High Court.

Because Egypt had never paid the yearly tribute that it had promised Baldwin III in 1160, Amalric, hoping to gain control of Egypt and break Muslim unity, invaded Egypt in 1163. During this unsuccessful attempt, Amalric's kingdom was attacked by the Syrian ruler Nureddin. Gradually the war became a contest for control of Egypt. Amalric appealed both to the Byzantine emperor Manuel I Comnenus and to Louis VII of France for help. Manuel agreed to lend his fleet for one of Amalric's campaigns, with the provision that Amalric divide Egypt with Byzantium. The expedition failed, but the Byzantine-Palestinian alliance was maintained. Upon Amalric's death his son Baldwin was crowned king of Jerusalem as Baldwin IV.

Amalric II, byname AMALRIC OF LUSIGNAN, French AMAURY, or AMAURI, DE LUSIGNAN (b. c. 1155—d. April 1, 1205), king of Cyprus (1194-1205) and of Jerusalem (1198-1205), who ably ruled the two separated kingdoms.

Amalric had been constable of Palestine before he was summoned by the Franks in Cyprus to become king there after the death of his brother Guy of Lusignan. Amalric planned a close alliance with Henry of Champagne, the uncrowned ruler of Palestine, betrothing his three sons to Henry's three daughters. He also became the vassal of the Holy Roman emperor Henry VI. On Henry of Champagne's accidental death (1197), Amalric, a widower, was induced to marry Henry's widow, Queen Isabella I, because the emperor's German advisers were hoping to get the Latin kingdom of Jerusalem (then only a thin strip of the Palestinian coast) as a fief like Cyprus. Amalric, however, though he was crowned in 1198, decided to administer Jerusalem separately and to regard himself as merely its regent.

As king of Jerusalem, Amalric was able to make peace with his Muslim neighbours, thanks to the struggle that took place among them after Saladin's death in 1193. Though both sides periodically broke the treaty, it was renewed in September 1204 for six years. On Amalric's death Cyprus was left to his six-year-old son, Hugh, and the kingdom of Jerusalem remained in Isabella's possession.

Amalthea, in Greek (originally Cretan) mythology, the foster mother of Zeus, king of

the gods. She is sometimes represented as the goat that suckled the infant god in a cave in Crete, sometimes as a nymph who fed him the milk of a goat. This goat having broken off one of its horns, Amalthea filled the horn with flowers and fruits and presented it to Zeus, who, according to one version, placed it, together with the goat, among the stars. In general, the horn was regarded as the symbol of inexhaustible riches and plenty and became the attribute of various divinities and of rivers as fertilizers of the land.

Amalthea, small, potato-shaped moon of Jupiter discovered in 1892 by the American astronomer E.E. Barnard. It circles Jupiter once about every 12 hours at a distance of 181,000 km (112,500 miles) in a nearly circular orbit that lies very close to Jupiter's equatorial plane. Images made by the Voyager spacecraft in 1979 and confirmed by the Galileo orbiter in the late 1990s show that Amalthea is an irregular rocky body measuring $262 \times 146 \times 134$ km ($163 \times 91 \times 83$ miles); it always keeps the same face toward the planet. Amalthea has a dark, reddish surface marked by impact craters. The red colour probably results from contamination by particles of sulfur and sulfur compounds that are continually shed by the nearby volcanically active moon Io.

Amambai Mountains, Portuguese SERRA DE AMAMBAÍ, Spanish CORDILLERA DE AMAMBAY, highlands in western Mato Grosso do Sul state, Brazil, and eastern Paraguay.

Extending south-southwest initially as the Maracaju Mountains for about 200 miles (320 km) from Campo Grande, the capital of Mato Grosso do Sul, they form the western side of the Brazilian Highlands and mark the divide between the tributaries of the Paraguay River and those of the Paraná. Like most of the highlands of the Mato Grosso, the Amambai Mountains are tabular uplands without sharp peaks. The average elevation is 1,300 feet (400 m) above sea level; the highest elevation is 2,300 feet (700 m). The southern end of the highlands forms part of the border between Brazil and Paraguay. Principal towns of the Amambai Mountains include Ponta Porã, Brazil, and Pedro Juan Caballero, Paraguay.

Amami Great Island, Japanese AMAMI-ŌSHIMA, largest island in the Amami chain of the northern Ryukyu Islands, in Kagoshima ken (prefecture), Japan. Most of the 274-square-mile (709-square-kilometre) island is mountainous and forested. A quasi-national park protects landscapes at the higher elevations. Mount Yūwan is the highest mountain at 2,276 feet (694 m). The lower, cultivated areas produce timber, sugarcane, and rice. A hydroelectric station operates on the Sumiyō River. Naze, the largest city, has a scientific research station and hospitals for senior citizens and retarded children. Naze and Setouchi are domestic shipping ports, and Setouchi has a museum. An airport is situated on Cape Kasari, and a highway connects Kasari and Setouchi. Pop. (1995 prelim.) 75,801.

Amana Colonies, settlement in Iowa county, east-central Iowa, U.S. It lies near the Iowa River, 20 miles (32 km) west-northwest of Iowa City, and comprises a group of seven small villages: Amana, East Amana, Middle Amana, High Amana, West Amana, South Amana, and Homestead.

Amana developed from the Community of True Inspiration, founded in 1714 in the German principality of Hesse by the pietistic mystics Johann Friedrich Rock and Eberhard Ludwig Gruber. The sect disintegrated after Rock's death in 1749, but it was revived in 1817 by Christian Metz and Barbara Heine-mann and became centred mainly in Würt-

temberg. The sect encountered hostility from the civil authorities because of its members' opposition to war, and in 1842 they migrated to the United States, purchasing land near Buffalo, N.Y., where they established the communal Ebenezer Society. In 1855 about 800 members moved westward to Iowa, where 18,000 acres (7,280 hectares; later expanded to 26,000 acres) had been purchased. This new home was called Amana (a mountain range in Lebanon referred to in Song of Solomon 4:8 and meaning "to remain true," or "to believe faithfully") and was incorporated in 1859. Members gave up their property to a common fund and in return were promised economic security through life. In addition to communal property and opposition to military service, the citizens of Amana opposed taking oaths, amusement, and a paid ministry.

The community prospered at first but began to decline after the American Civil War. Financial disaster caused by the Depression necessitated its reorganization in 1932. Communal property was dissolved, and the villages were organized on the basis of a joint stock corporation, called the Amana Society, with the workers as stockholders. In addition to its farms, the Amana Society operates factories that produce woolens, furniture, wines, bakery goods, and meat specialties. Amana Refrigeration, Inc., formerly a division of the Amana Society, manufactures refrigerators, freezers, and microwave ovens.

The Amana Church Society, separately organized in 1932, continues its pietistic emphasis and remains the dominant force in the community. Simple worship services are conducted in German in unadorned village churches. The church society, which is governed by elected elders and has no ordained clergy, reported 600 members in four churches in the late 1970s. Pop. (1999 est.) 1,490.

Amanita, genus of about 100 species of mushrooms of the family Amanitaceae, order Agaricales, some of which are poisonous to humans. The amanitas typically have white spores, a ring on the stem slightly below the cap, a veil (volva) torn as the cap expands, and a cup from which the stalk arises. Among the deadliest of all mushrooms are the destroying angels (*A. bisporigera*, *A. ocreata*, *A. verna*, and *A. virosa*). They develop a large white fruiting body and are found in forests during wet periods in summer and autumn.

Destroying angel (*Amanita verna*)
Mary W. Ferguson

Death cap (*A. phalloides*), also deadly, is found in woods or their borders. It has a green

Fly agaric (*Amanita muscaria*)
Larry C. Moon—Tom Stack & Associates

or brown cap and appears in summer or early autumn. Other poisonous species include *A. brunnescens* and *A. pantherina*; common edible species include *A. caesarea*, *A. rubescens*, and *A. vaginata*.

The fly agaric, or fly amanita (*A. muscaria*), is a poisonous mushroom found in pastures and fields in summer. It was once used as a fly poison. See also mushroom poisoning.

Amānollāh Khān (b. June 1, 1892, Paghmān, Afg.—d. April 25, 1960, Zürich, Switz.), ruler of Afghanistan (1919–29) who led his country to full independence from British influence.

Amānollāh, 1928
BBC Hulton Picture Library

A favoured son of the Afghan ruler Ḥabībollāh Khān, Amānollāh took possession of the throne immediately after his father's assassination in 1919, at a time when Great Britain exercised an important influence on Afghan affairs. In his coronation address Amānollāh declared total independence from Great Britain. This led to war with the British, but fighting was confined to a series of skirmishes between an ineffective Afghan army and a British Indian army exhausted from the heavy demands of World War I. A peace treaty recognizing the independence of Afghanistan was signed at Rāwalpindi (now in Pakistan) in August 1919.

Although a charming man and a sincere patriot and reformer, Amānollāh was also impulsive and tactless and tended to surround himself with poor advisers. Shortly after ascending the throne, he pushed for reforms, in-

cluding an education program and road-building projects, but was opposed by reactionaries. In 1928 he returned from a trip to Europe with plans for legislative reform and emancipation of women, proposals that caused his popular support to drop and enraged the mullahs (Muslim religious leaders). In 1928 a tribal revolt resulted in a chaotic situation during which a notorious bandit leader, Bachcheh Saqow, seized Kābul, the capital city, and declared himself ruler. Amānollāh attempted to regain the throne but, for reasons that are unclear, failed to do so. He abdicated in January 1929 and left Afghanistan for permanent exile that May.

Amapá, *estado* ("state"), northern Brazil. It is bounded on the north by a small portion of Suriname and by French Guiana, on the northeast by the Atlantic Ocean, on the south and west by the Brazilian state of Pará, and on the southeast by the Amazon River. Formerly a part of Pará state, Amapá was created a territory in 1943 and became a state in 1990, with its capital at Macapá (*q.v.*). Most of its 54,161 square miles (140,276 square km) is tropical rain forest, but there are patches of savanna along the coast, which has long remained scantily populated. The major products are cabinet woods (mahogany, cedar, pine, eucalyptus, rosewood), medicinal plants, wild-animal skins, rubber, jute, Brazil nuts, fish, crustaceans, and mollusks. Gold is found in the stream gravels. Amapá is known primarily for the large manganese and iron-ore mines inland from Macapá. In the late 1970s factories were built to produce ferromanganese and silicomanganese from the mines' ore. Oil was discovered in the continental shelf off Amapá state, and exploratory wells were drilled. Macapá's port (Pôrto Santana), highways, and railroad link Macapá to the state's interior and to northwestern Brazil. Pop. (1989 est.) 248,100.

Amar Dās (b. 1479, Khadur?, India—d. 1574, Goindwal), third Sikh Guru, appointed at the advanced age of 73, noted for his division of the Punjab into 22 Sikh dioceses and his dispatch of missionaries to spread the faith. Realizing that periodical meetings of all Sikhs would strengthen the faith, he ordered three great festivals a year. He was much revered for his wisdom and piety, and it was said that even the Mughal emperor Akbar sought his advice and ate in the Sikhs' casteless *laṅgar* (free "kitchen"). Under Amar Dās's direction, the city of Goindwal became a Sikh centre of learning.

Gurū Amar Dās advocated a middle way of life between the extremes of asceticism and sensuous pleasure, and he praised the life of the ordinary family man. Thus a man could enjoy prosperity and please God also. Among his social reforms, he further extended the *laṅgar* and made it a rule that anyone wanting to see him must first eat in the kitchen. He purified the Sikh religion of Hindu practices, encouraged intercaste marriage, and allowed widows to remarry. He also strictly enjoined his followers to refrain from the prevailing Hindu practice of suttee (self-immolation of a widow on her husband's funeral pyre).

ʿAmārah, al-, city, southeastern Iraq. Situated on a low ridge beside the Tigris River, it is Iraq's chief port on that waterway south of Baghdad. It is a trade centre for agricultural produce, livestock, wool, and hides and is known for weaving and silverware. In World War I it was captured by the British during their 1915 Mesopotamia campaign. Before 1958, al-ʿAmārah was an outstanding example of autocratic rule by sheikhs, who owned large estates in this rice-growing area and also maintained large private armies. After the overthrow of the monarchy, land distribution gradually became more democratic. Pop. (1985 est.) 131,758.

Amaranthaceae, the amaranth family of flowering plants in the order Caryophyllales, with about 60 genera and more than 800 species of herbs, with a few shrubs, trees, and vines, native to tropical America and Africa. The leaves of members of the family usually have nonindented edges. Flowers may be

Love-lies-bleeding (*Amaranthus caudatus*)

A J Huxley

male or female or contain both types of reproductive structures; several leaflike bracts are present below each flower; and the fruit may be a capsule, utricle, drupe, or berry. Species of globe amaranth (*Gomphrena*) and cockscomb (*Celosia*) are cultivated as ornamentals; the genera *Alternanthera* and *Iresine* each have several species that are cultivated as bedding plants for their attractive and colourful leaves. The genus *Amaranthus* contains the ornamentals love-lies-bleeding, or tassel flower (*A. caudatus*), prince's feather (*A. hybridus erythrostachys*), and Joseph's-coat (*A. tricolor*) and many weedy plants known as pigweed, especially *A. retroflexus*. Prostrate pigweed (*A. graecizans*) and white pigweed (*A. albus*) are common throughout Europe in cultivated and waste areas. Tumbleweed (*A. albus*), a widespread weed in the western United States, has been introduced elsewhere in the world.

Some *Amaranthus* species are potential high-protein grain crops; strains are being bred for high yield and seedhead stability.

Amarapura, town, central Myanmar (Burma). It lies on the left bank of the Irrawaddy River. A suburb of Mandalay, it is also known as Taung-myo (Southern Town) or Myohaung (Old City). Founded by King Bodawpaya in 1783 as his new capital, it supplanted Ava, 6 miles (10 km) southwest. Its population in 1810 was estimated at 170,000, but a fire that year and the return of the court to Ava in 1823 caused a decline to about 30,000 by 1827. King Tharrawaddy (reigned 1837–46) restored Amarapura as the capital, but an earthquake in 1839 destroyed much of the city, which was finally abandoned for Mandalay by King Mindon Min in the late 1850s. Ruined walls indicate that Amarapura, called the "City of Immortals," was laid out as a square with sides $\frac{3}{4}$ mile (1 km) long. A solid brick pagoda, 100 feet (30 m) high, stood at each corner of the walls; a celebrated temple with 250 pillars of gilt wood contained a colossal bronze statue of Buddha. The tombs of Bodawpaya and his successor, Bagyidaw, are in the city.

Long known for its silk weaving, Amarapura is the site of a weaving school. Colourful *longyis* (skirts worn by both sexes) are produced in a distinctive heavy silk. The town's long-established bronze industry is famous for Buddha figures, bells, and gongs. Tile, pottery, and baskets are also manufactured. Amarapura lies along the Rangoon-Mandalay railway and also serves as the junction for Lashio and Myitkyinā. Near the old city, one of a

chain of lakes is crossed by U Bein's Bridge, which leads to the Taungthaman Kyauktawgyi pagoda. Pop. (latest census) 10,519.

Amaravalli (India): see Amreli.

Amarāvati, also spelled AMARAVATHI, town, east-central Andhra Pradesh state, southern India. Situated on the Krishna River, it was an ancient Buddhist centre in the region. Its monasteries and university attracted students from throughout India and the Far East. The Buddhist stupa at Amarāvati was one of the largest in India, though only traces of it now remain. Amarāvati is known for the relief sculptures that were a part of its great Buddhist shrine, although most of these are now in museums, including a museum in Amarāvati.

Amarāvati sculpture, Indian sculpture that flourished in the Andhra region of southeastern India from about the 2nd century BC to the end of the 3rd century AD, during the rule of the Sātavāhana dynasty. It is known for its superb reliefs, which are among the world's finest examples of narrative sculpture.

In addition to the ruins of the great stupa, or relic mound, at Amarāvati, the style is also seen in the stupa remains at Jaggayyapeta, Nāgārjunikoṇḍa, and Goli, in Andhra Pradesh state, and as far west as Ter, Mahārāshtra state. The style also spread to Ceylon (now Sri Lanka), as seen at Anurādhapura, and to much of Southeast Asia.

Dream of Māyā presaging the Buddha's birth, marble relief from Nāgārjunikoṇḍa, Andhra Pradesh state, India, Amarāvati school, c. 3rd century AD; in the Indian Museum, Calcutta

P. Chandra

The Amarāvati stupa was begun about 200 BC and underwent several renovations and additions. One of the largest stupas built in Buddhist India, it was about 160 feet (50 m) in diameter and 90 to 100 feet (about 30 m) high, but it has been largely destroyed, much of the stone having been used by local contractors during the 19th century to make lime mortar. Many of the surviving narrative reliefs and decorative plaques are in the Government Museum, Madras, and the British Museum. A depiction of the monument on a railing slab gives an indication of the appearance of the stupa at the end of the 2nd century AD. The slab shows a low drum with a hemispherical dome, the railings and drum covered with carvings, and the whole surrounded by an elaborate and richly carved railing. The four cardinal points are marked by groups of five pillars, while free-standing columns topped by lions are set up at the four entrances, replacing the *torāṇa* (ceremonial gateway) of earlier stupas.

The reliefs, carved on the greenish white limestone characteristic of the region, mostly depict events of the Buddha's life and his previous births (*Jātaka* stories). The crowded yet unified compositions of the later period are filled with dynamic movement, a keen awareness of the dramatic, and a delight in the sensuous world. Overlapping figures and the use of diagonals suggest depth. There is an abundance of rounded forms and a richness so overwhelming that the frame is barely able to contain the sculpture. The four centuries over which the style developed were also a period of change from aniconic to iconic representation of the Buddha, and at Amarāvati both methods of depiction appear together on one slab—the iconic being represented by images of the seated and standing Buddha, and the aniconic by an empty throne symbolizing his presence.

Amargosa Range, group of mountains in eastern California and southern Nevada, U.S., separating Death Valley from the Amargosa Desert. Part of the Basin Ranges of eastern California, the Amargosa Range extends 110 miles (180 km) from Grapevine Peak (8,705 feet [2,653 m]), south-southeastward to the Amargosa River. It is composed of three distinct mountain groups: the Grapevine, Funeral, and Black. Dante's View, in the Black Mountains, rises to 5,475 feet (1,669 m) and provides a clear view of Death Valley and the Panamint Range, which lies beyond it.

Amarillo, city, seat (1887) of Potter county (and partly in Randall county), on the high plains of northern Texas, U.S. Now the chief city of the Texas Panhandle, it originated in 1887 as a railroad construction camp and grew after 1900 when wheat cultivation and ranching became important in the region. The discovery of petroleum and natural gas deposits in the 1920s further promoted the community's development as a regional and industrial centre, though in the 1930s the general economic depression and prolonged drought restricted growth. After 1940, however, extensive irrigation from underground water increased agricultural output. In addition to oil, farming, and ranching, the city has a large copper refinery and ordnance and helicopter factories. Helium is found in large quantities in the area, and Amarillo is the site of a major helium plant and an unusual monument (a six-story stainless steel column built in 1968 to commemorate the element).

Amarillo College, with the Amarillo Art Center on its campus, was founded in 1929. The city has a notable medical centre, holds a huge livestock auction, and is the headquarters of the American Quarter Horse Association. West Texas State University (1910) is at nearby Canyon. Palo Duro Canyon State Park is 16 miles (26 km) southeast, and Buffalo Lake National Wildlife Refuge is southwest. The name Amarillo probably comes from the Spanish word for yellow, the colour of local clay deposits. Inc. 1892. Pop. (1990) city, 157,615; Amarillo MSA, 187,547.

Amarinya language: *see* Amharic language.

Amarna, Tell el-, also spelled TALL AL-AMARNA, or TEL EL-AMARNA, site of the ruins and tombs of the city of Akhetaton ("Horizon of Aton") in Upper Egypt, 44 miles (71 km) north of modern Asyūt in al-Minyā *muḥāfaẓah* (governorate). On a virgin site on the east bank of the Nile, Akhenaton (Amenhotep IV) built the city in about 1348 BC as the new capital of his kingdom when he abandoned the worship of Amon and devoted himself to that of Aton. About four years after Akhenaton's death (c. 1332) the court returned to Thebes, and the city was abandoned.

Model of a noble's estate at Tell el-Amarna

By courtesy of the Oriental Institute the University of Chicago

Though it had a brief existence, Akhetaton is one of the few ancient Egyptian cities that has been carefully excavated. Because Akhenaton chose a virgin site for his capital and because of the relatively short duration of its occupancy, the excavators could reconstruct an unusually accurate picture of the layout of the city.

The principal buildings of Akhetaton lay on either side of the Royal Road, the largest of them being the Great Temple of the Aton, primarily a series of walled courtyards leading to the completely open-air main sanctuary. Near the Great Temple were the palace and the commodious residence of the royal family. Most of the dwellings at Tell el-Amarna were of baked mud brick, and the walls, floors, and ceilings of many of the rooms were painted in a lively naturalistic style; each large house had a shrine with a stela including scenes depicting the intimate family life of Akhenaton.

Among other major archaeological finds were portrait busts of Queen Nefertiti in the house of the sculptor Thutmose, as well as 300 cuneiform tablets accidentally discovered in 1887 by a peasant woman. From them it was possible to trace the fortunes of the Egyptian empire in the late 18th dynasty.

Unlike those of Thebes, the nobles' villas at Akhetaton had only one floor; the roof of the central living room, however, was usually higher than the rest of the house, thus permitting clerestory lighting and ventilation. The workers lived in simple row houses.

Officials' tombs, resembling those at Thebes, were hewn into the desert hills to the east. Although the painted reliefs in the tomb chapels often appear to have been hastily carried out, they have been a major source of information on the daily life and religion of Akhenaton. Also, the drawings on the tomb walls depicting various buildings of the city helped the excavators to interpret the often meagre architectural remains. The reliefs, in an unconventional, often exaggerated style, tend to reflect a momentary aspect rather than the static mood that had characterized earlier Egyptian art.

The tomb of Akhenaton and his family, situated in the side of a dry watercourse east of the city, contained an unprecedented scene of the royal family in mourning over the death of the princess Mekhetaton, who was buried there. Excavations in the 1890s and late 1970s yielded fragments of Akhenaton's deliberately smashed sarcophagus and numerous broken ushabti.

When Tutankhamen transferred the residence back to Thebes, he moved the royal burials to the Theban necropolis, where Smenkhkare and Queen Tiy were found in a cache of royal mummies.

After Akhetaton's abandonment, Horemheb razed the city and Ramses II reused the stone blocks of its temples for his work at nearby Hermopolis.

Amarna style, also called TELL EL-AMARNA STYLE, revolutionary style of Egyptian art created by Amenhotep IV, who took the name Akhenaton during his reign (1353–36 BC) in

the 18th dynasty. Often referred to as the Amarna heresy, Akhenaton's alteration of the artistic and religious life of Egypt was drastic. He laid the greatest stress on his own divinity as the manifestation of the god whom he designated the supreme and only deity, Aton, the sun disk. This sun cult, which revived ancient usages, was practiced to the exclusion of worship of the entire Egyptian pantheon, including Amon-Re, formerly considered king of the gods and patronized liberally by Akhenaton's father. Not content to erect temples to Aton merely in Thebes, the capital, Akhenaton moved to the edge of the desert, near the present Tell el-Amarna, and named his new capital Akhetaton ("Horizon of Aton").

After the banishment of all Egyptian gods except Aton, Akhenaton limited artistic subject matter mainly to depictions of himself and his family, both in casual domestic scenes, which were his favourite, and in concert with Aton, who was shown as a golden orb radiating beams of light that ended in little hands proffering the sign of life, the ankh, to Akhenaton and his queen, Nefertiti. It was in the method of portraying the Pharaoh and his family that the most remarkable aspect of Amarna art lies, for the old stiff canon was abandoned in favour of a "naturalistic" depiction, which showed them more as actual human beings. Essentially it was a secularization of art that took place; the royal family was now shown in the same casual poses and settings as servants and commoners had been depicted in the past. Some experts see the depictions of Akhenaton himself—with an elongated head, slender neck and limbs, and protruding belly—as artistic overstatements of basically real physical attributes, possibly the result of a rare disease that deformed his head and hips. Whatever the reason, the expressionistic physical type eventually became canonized and was used to some degree in most depictions of human form throughout the Amarna period.

Painted wall reliefs found in the tombs of Akhetaton officials reveal much about everyday life there, as opposed to the life-after-death scenes usually found in tombs. Painted scenes spread from wall to wall, ignoring the traditional practice of dividing pictorial space into

"Daughters of Akhenaton," fragment of a wall painting from a small residential building of Akhetaton, Tell el-Amarna, New Kingdom, 18th dynasty; in the Ashmolean Museum, Oxford
Holle Bildarchiv, Baden-Baden

registers, or horizontal bands. A love of natural form developed, and pure landscape came into its own as subject matter. Portraits, in the form of busts and masks, were done for their own sake.

Neither the artistic revolution nor the worship of Aton survived Akhenaton. The great temple was razed to the ground by opponents of the Aton cult, and Akhenaton's name was deleted from official king lists, being referred to thereafter as "that criminal of Akhetaton." His successor, the young Tutankhamen, attempted to return to more traditional artistic ideas, but Amarna influence is still evident in the art of this period. Throughout the remainder of the 18th dynasty, a steady purge of unorthodox artistic elements continued, and, by the reign of Horemheb, rigid formality had returned.

INDEX
first

Amaryllidaceae, family of perennial herbs in the flowering plant order Liliales, containing about 65 genera and at least 835 species, distributed primarily in tropical and subtropical areas of the world. Members of the family have bulbs or underground stems; several strap- or lance-shaped leaves grouped at the base of the stem or arranged alternately along the stem; flowers usually with three petals and three sepals; and dry, capsule-shaped, and fleshy or berrylike fruits.

Many species are cultivated as garden ornamentals, especially belladonna lily (*Amaryllis belladonna*), tuberose (*Polianthes*), snowdrop (*Galanthus*), snowflake (*Leucojum*), and daffodil (*Narcissus*). Many tropical lilylike plants also belong to the family, such as those of the genera *Haemanthus* (Cape tulip, or blood lily), *Alstroemeria* (Peruvian lily), and *Hippeastrum*. An ornamental Eurasian plant known as winter daffodil (*Sternbergia lutea*) is often cultivated in borders or rock gardens. *Clivia miniata*, a South African perennial, is cultivated as a houseplant for its scarlet flowers lined with yellow.

Amasis (kings of Egypt): see Ahmose I; Ahmose II.

Amasis Painter (fl. c. 555–525 BC), ancient Greek vase painter who, with Exekias, was among the most accomplished of Archaic vase

painters. He was responsible for the decoration of several of the black-figure amphorae (two-handled jars), *cenochosae* (wine pitchers), and lekythoi (oil flasks) of the Amasis Potter.

Signatures of the Amasis Painter have been recognized on eight vessels. Among those thought to have been decorated by him are a Dionysus and the Maenads now in the Bibliothèque Nationale at Paris; an "Apollo and Heracles" in the Boston Museum of Fine Arts; and a wedding procession in the Metropolitan Museum of Art, New York City.

Amasya, historically, AMASEIA, or AMASIA, city, capital of Amasya il (province), northern Turkey, on the Yeşil River, also called the Iris River. Capital of the kings of Pontus until about 183 BC, it was made a free city and the administrative centre of a large territory by Pompey in 65 BC. In the 2nd century AD, it received the titles "metropolis" and "first city" under the Romans. It was the capital of the Turkmen Dānişmend emirs until annexed by the Seljuq ruler Qilic Arslan a century later. It became a major centre of learning in Anatolia after being incorporated into the Ottoman

Amasya, Tur., on the Yeşil River, flanked by a gorge (right)

Maynard Williams—Shostal/EB Inc

Empire by Sultan Bayezid I (reigned 1389–1402).

Beautifully situated in a narrow gorge with renowned orchards, it was much favoured by the early Ottomans; crown princes often served as governors. A castle mentioned by the ancient geographer Strabo, who was born there, now lies in ruins on the summit of a rock, though it was restored during Byzantine and Ottoman periods. Notable medieval buildings include several mosques and a library. Old buildings are concentrated on the heavily populated southern side of the river, connected to the north by five bridges. Many monuments were damaged by earthquakes in 1734, 1825, and 1939.

Amasya, between the Black Sea and inner Anatolia, lies at the centre of a region of fertile plains crossed by the Yeşil, Çekerek, and Tersakan rivers. Regional economic activities include agriculture, mining, textiles, and cement production. Pop. (1985) city, 53,431.

Amaterasu, in full AMATERASU ŌMIKAMI (Japanese: "Great Divinity Illuminating Heaven"), the celestial sun goddess from whom the Japanese imperial family claims descent, and an important Shintō deity. She was born from the left eye of her father, Izanagi, who bestowed upon her a necklace of jewels and placed her in charge of Takamagahara ("High Celestial Plain"), the abode of all the *kami*. One of her brothers, the storm god Susanoo, was sent to rule the sea plain. Before going, Susanoo went to take leave of his sister. As an act of good faith, they produced children together, she by chewing and spitting out pieces of the sword he gave her, and he by doing the same with her jewels. Susanoo then began to behave very rudely—he broke down the divisions in the rice fields, defiled his sister's dwelling place, and finally threw a flayed horse into her weaving hall. Indignant, Amaterasu withdrew in protest into a cave, and darkness fell upon the world.

The other 800 myriads of gods conferred on how to lure the sun goddess out. They collected cocks, whose crowing precedes the dawn, and hung a mirror and jewels on a *sakaki* tree in front of the cave. The goddess Amenouzume (*q.v.*) began a dance on an upturned tub, partially disrobing herself, which so delighted the assembled gods that they roared with laughter. Amaterasu became curious how the gods could make merry while the world was plunged into darkness and was told that outside the cave there was a deity more illustrious than she. She peeped out, saw her reflection in the mirror, heard the cocks crow, and was thus drawn out from the cave. The *kami* then quickly threw a *shimenawa*, or sacred rope of rice straw, before the entrance to prevent her return to hiding.

Amaterasu's chief place of worship is the Grand Shrine of Ise, the foremost Shintō shrine in Japan. She is manifested there in a mirror that is one of the three Imperial Treasures of Japan (the other two being a jeweled necklace and a sword). The genders of Amaterasu and her brother the moon god Tsukiyomi no Mikato are remarkable exceptions in worldwide mythology of the sun and the moon. See also Ukemochi no Kami.

Amateur Athletic Association (AAA), British national governing organization for the sport of track and field (athletics). Founded in 1880, it took over as the governing power from the Amateur Athletic Club, founded in 1866. The association was the first such organization in the world. The AAA was one of the first groups to reject the requirement of upper-class background that had previously been necessary to achieve amateur athletic status.

The AAA promotes, organizes, and regulates athletic competition, coaching, and training and holds annual national and junior national championships. Association headquarters is in London.

Amateur Athletic Union of the United States (AAU), alliance of national and district associations, amateur athletic groups, and educational institutions formed in the United States in 1888 for the purpose of certifying athletes as amateurs in various sports. The AAU now serves as the governing body of numerous sports, including basketball, boxing, gymnastics, handball, swimming, diving, water polo, wrestling, weight lifting, track and field, bobsledding, luge, horseshoe pitching, judo, baton twirling, and karate. It also supervises tryouts for Olympic competitors and plays an important role in raising funds for U.S. Olympic athletes. The James E. Sullivan Memorial Trophy, named for an early AAU official, is awarded annually to the nation's outstanding amateur athlete. Publications include *Amateur Athlete* (monthly) and sports guides and rule books. Its headquarters is in Indianapolis, Ind.

amateur radio, noncommercial, two-way radio communications. Messages are sent either by voice or in International Morse Code.

Interest in amateur radio arose around the turn of the century, shortly after the Italian inventor Guglielmo Marconi successfully sent the first transatlantic wireless signal in 1901. The interference of amateur broadcasts with commercial and military transmissions led to the institution of government control in 1911. After World War I, amateurs became active in radio experimentation, contributing to developments in long-distance broadcasting and becoming the first radio operators successfully to exploit the upper medium-frequency and lower high-frequency radio bands. Over the years, amateur radio operators have also provided emergency communications during

"Dionysus and the Maenads," amphora by the Amasis Painter, c. 530 BC; in the Cabinet des Médailles, Paris

Hirmer Fotoarchiv, München

forest fires, floods, hurricanes, and other disasters. They serve as an important link between stricken communities and the outside world until normal communications are reestablished.

Amateur radio operators in the United States are subject to international and federal regulations. There are five classes of licenses. Competence in the use of the International Morse Code and a knowledge of radio theory and regulation are required to obtain the advanced-level licenses. Amateur radio is allocated frequencies at the extreme high-frequency end of the medium-wave band, five groups of frequencies in the shortwave band, two groups in the very-high-frequency band, three in the ultrahigh-frequency band, and seven in the superhigh-frequency band for telegraphic and telephonic communication using amplitude and frequency modulation. There are restrictions on the power of the transmitters, and certain of the frequencies must be shared with due regard for the needs of other users.

Amathus, ancient city located near Limassol, Cyprus, among sandy hills and sand dunes, which may explain its name (Greek *amathos*, "sand"). Founded by the Phoenicians (c. 1500 BC), Amathus maintained strong sympathies with the Phoenician mainland and refused to join various Cypriot revolts against Persia. When the rest of Cyprus was annexed to Egypt after the death of Alexander the Great, Amathus resisted annexation. It derived its wealth from grain and from copper mines. Its temple of Adonis and Aphrodite was famous in Roman times, hence the Latin epithet *Amathusia* applied to Venus. The city still flourished in the 7th century AD but was almost deserted by the 12th century.

Amati FAMILY, a family of celebrated Italian violin makers in Cremona in the 16th and 17th centuries.

Andrea (c. 1520–c. 1578), the founder of the Cremona school of violin making, was perhaps originally influenced by the work of slightly earlier makers from Brescia. His earliest-known violins are dated about 1564. In essentials, they set the style for all the models made by later members of the family and, with the modifications introduced by Antonio Stradivari, for the modern violin. Andrea made violins in two sizes, the larger of which later became known as the "grand Amati." He also introduced the characteristic amber-coloured varnish.

Andrea's two sons Antonio (c. 1550–1638) and Girolamo (Hieronymus; 1551–1635) worked together until the latter's death and are known as the brothers Amati.

Nicolò (1596–1684) was the son of Girolamo. The most famous of the family, he produced instruments notable for beauty of workmanship and tone and was the master from whom Stradivari and Andrea Guarneri, among others, learned their craft. He was succeeded by his son Girolamo (1649–1740). Although the instruments made by Girolamo are as fine as those of his father and grandfather, they suffered in comparison with those made by Stradivari.

The great contribution of the Amatis to the development of the violin was their evolution of the flat, shallow model, which, as improved by Stradivari, proved the fittest to survive in modern concert conditions by reason of the brilliant soprano tone of which it is capable.

Amatique Bay, Spanish *BAHÍA DE AMATIQUE*, inlet of the Gulf of Honduras in the Caribbean Sea, indenting eastern Guatemala and southeastern Belize (formerly British Honduras). Extending northwestward for about 40 miles (64 km) from Santo Tomás de Castilla, Guatemala, it is some 15 miles (24 km) from

northeast to southwest. Amatique Bay receives the Dulce River, which drains Izabal Lake; the Sarstoon (Sarstún) River, which forms the Belize-Guatemala border; and, in the northwest, the Moho River. The bay's principal ports are Puerto Barrios (*q.v.*), Santo Tomás de Castilla, and Livingston, in Guatemala; and Punta Gorda, in Belize.

Amatitlán, Lake, Spanish *LAGO DE AMATITLÁN*, lake, south-central Guatemala, in the central highlands at 4,085 feet (1,248 m) above sea level. The volcanic lake, 130 feet (40 m) deep, is 7 miles (11 km) long and 2 miles (3 km) wide and has an area of about 6 square miles (15 square km). It is fed by the Villalobos River and drained by the Michatoya River. A popular tourist area, the lake and the town of Amatitlán, at the head of the Michatoya, are situated by highway south-southwest of Guatemala City.

amaurotic familial idiocy: *see* Tay-Sachs disease.

Amaury, also spelled *AMAURI* (kings of Jerusalem): *see under* Amalric.

Amazon, in Greek mythology, member of a race of women warriors. The story of the Amazons probably originated as a variant of a tale recurrent in many cultures, that of a distant land organized oppositely from one's own. The ascribed habitat of the Amazons necessarily became more remote as Greek geographic knowledge developed. When the Black Sea was colonized by Greeks, it was first said to be the Amazon district; but when no

The Mattei Amazon, Roman copy after an original attributed to Phidias, c. 440 BC; in the Vatican Museum
Alinari—Art Resource

Amazons were found there, it was necessary to explain what became of them. Traditionally, one of the labours required of the Greek hero Heracles was leading an expedition to obtain the girdle of the Amazons' queen (Hippolyte), during which he was said to have conquered and expelled them from their district.

Subsidiary tales grew up to explain why, if the whole nation consisted of women, it did not die out in a generation. The most common explanation was that the Amazons mated with men of another people, kept the resulting female children, and sent the male children away to their fathers. In another tale, Theseus attacked the Amazons either with Heracles or independently. The Amazons in turn invaded Attica but were finally defeated, and at some

point Theseus married one of them, Antiope. In Hellenistic times the Amazons were associated with Dionysus (the god of wine), either as his allies or, more commonly, as his opponents.

Ancient Greek works of art often depicted combats between Amazons and Greeks, and the confrontation between Theseus and the Amazons was a particular favourite. As portrayed in these works, the Amazons were similar in model to the goddess Athena, and their arms were the bow, spear, light double ax, a half shield, and, in early art, a helmet. In later art they were more like the goddess Artemis and wore a thin dress, girded high for speed; on the later painted vases their dress is often peculiarly Persian.

According to some accounts, the Amazon River was named by the 16th-century Spanish explorer Francisco de Orellana for the fighting women he claimed to have encountered on what was previously known as the Marañon River.

Amazon Rain Forest, large, tropical rain forest occupying the drainage basin of the Amazon River and its tributaries in northern South America, and covering an area of 2,300,000 square miles (6,000,000 square km). Comprising about 40 percent of Brazil's total area, it is bounded by the Guiana Highlands to the north, the Andes Mountain Ranges to the west, the Brazilian central plateau to the south, and the Atlantic Ocean to the east.

A brief treatment of the Amazon Rain Forest follows. For full treatment, *see* *MACROPAEDIA*: South America.

The Amazon River valley is the largest basin area in the world, and its rain forest stretches from the Atlantic Ocean in the east to the tree line of the Andes in the west. The rain forest widens from a 200-mile (320-kilometre) front along the Atlantic to a belt 1,200 miles (1,900 km) wide where the lowlands meet the Andean foothills. The immense extent and great continuity of this forest is a reflection of the high rainfall, high humidity, and monotonously high temperatures that prevail in the region.

The Amazon Rain Forest is the world's richest and most varied biological reservoir, containing several million species of insects, plants, birds, and other forms of life, many still unrecorded by science. The luxuriant vegetation encompasses a wide variety of trees, including many species of myrtle, laurel, palm, and acacia, as well as rosewood, Brazil nut, and rubber tree. Excellent timber is furnished by the mahogany and the Amazonian cedar. Major wildlife includes jaguar, manatee, tapir, red deer, capybara and many other types of rodents, and several types of monkeys.

In the 20th century, Brazil's rapidly growing population settled major areas of the Amazon Rain Forest. The Amazon forest shrank dramatically as a result of settlers' clearance of the land to obtain lumber and to create grazing pastures and farmland. In the 1990s the Brazilian government and various international bodies began efforts to protect parts of the forest from human encroachment, exploitation, and destruction.

Amazon River, Portuguese *RIO AMAZONAS*, Spanish *RÍO AMAZONAS*, greatest river of South America and the largest in the world in volume and area of its drainage basin.

A brief treatment of the Amazon River follows. For full treatment, *see* *MACROPAEDIA*: South America.

Originating within 100 miles (160 km) of the Pacific Ocean at its westernmost source high in the Peruvian Andes, the Amazon flows almost 4,000 miles (6,400 km) across northern Brazil to its mouth in the Atlantic Ocean on the northeastern coast of Brazil. Its length is second only to that of the Nile. It is estimated that about 20 percent of all the water that runs off the Earth's surface is carried by

the Amazon. The flood-stage discharge at the river's mouth is about 6,360,000 cubic feet (180,000 cubic m) per second, which is more than 10 times that of North America's Mississippi River and four times that of the Congo (Zaire) River in Africa. The discharge is so great that it turns the ocean's water from salty to brackish for more than 100 miles offshore.

There are more than 1,000 known tributaries of the Amazon, rising in the Guiana Highlands, the Brazilian Highlands, and (principally) the Andes. Seven of these are longer than 1,000 miles (1,600 km); one, the Madeira, flowing northeastward from Bolivia, is more than 2,000 miles (3,200 km) long. Navigable throughout the year, the Amazon can accommodate large freighters as far inland as Manaus, 1,000 miles upriver from the Atlantic. The Amazon flows over a gently sloping terrain and is characterized by oxbow lakes, abandoned channels, and other marks of a meandering river. Floods, by depositing fertile silt as they recede, annually rejuvenate an area of some 25,000 square miles (65,000 square km), or nearly double that of The Netherlands, and the river's total drainage basin, about 2,700,000 square miles (7,050,000 square km), is nearly twice as large as the area drained by any other river in the world. The Amazon and its tributaries may be described as a vast sea of freshwater, supporting millions of fish, including catfish, electric eels, and piranhas.

Amazonas, largest *estado* ("state") of Brazil, situated in the northwestern part of the country. It is bounded to the northwest by Colombia, to the north by Venezuela and the Brazilian state of Roraima, to the east and southeast by the Brazilian states of Pará and Mato Grosso, to the south by the Brazilian state of Rondônia, to the southwest by the Brazilian state of Acre, and to the west by Peru. Despite its size, it is one of the most thinly populated Brazilian states. Amazonas occupies the greater part of the tropical forest zone of the Amazon River basin. The capital, Manaus, is located in the eastern part of the state at the confluence of the Negro River with the mainstream of the Amazon.

The Spanish explorer Francisco de Orellana passed through this region in 1541–42 during a voyage down the Amazon from the Coca, one of its Andean headwaters, to its Atlantic estuary. In 1669 a Portuguese captain, Francisco da Mota Falcão, founded the fort of São José do Rio Negro on the site of the present Manaus; and in 1755 the captaincy of São José do Rio Negro was established in the region. After Brazilian independence Rio Negro remained dependent on the state of Pará until 1850, when it gained autonomy, becoming the province of Amazonas in 1852. After the overthrow of Brazil's imperial regime in 1889, the province became a federal state, adopting a constitution in 1891. From 1880 until its decline in 1910, the rubber trade brought prosperity to Amazonas, for which a modern port was constructed at Manaus by 1900. In 1946 the Brazilian government launched a plan for the economic development of Amazonia that has been continued to the present.

Except on the northern borders, where Neblina Peak reaches 9,888 feet (3,014 m), the highest point in Brazil, the state's mean elevation is not more than 300 feet (90 m) above sea level. The mainstream of the great Amazon River (known as the Solimões River from the Peruvian frontier to the Negro River confluence) traverses the state from west to east; its major tributaries are the Iça, the Japurá, and the Negro rivers from the north and the Javari, the Juruá, the Purus, and the Madeira from the south. With an annual average temperature of 79° F (26° C) and an annual rainfall of 80 inches (2,000 mm), the climate is warm and extremely humid. Apart from small areas of savanna (grassy parkland)

on the northern borders, equatorial rain forest covers virtually the entire state.

The native animal life is numerous and varied. Mammals are represented by monkeys, bats, and rodents; birds by ant thrushes, parrots, toucans, and various marsh birds; and reptiles by caymans, turtles, boas, anacondas, and iguanas.

Most of the people of the areas remote from the Amazon mainstream live in settlements on the banks of its tributaries. Nearly all of the rural population consists of caboclos—persons of mixed European and American Indian descent. There is also a large group descended from immigrants from northeastern Brazil who arrived during the rubber boom. The Indian population in the late 20th century was estimated at 60,000, or one-fifth of the total Indian population in Brazil. The Indian groups, of which about 30 may be distinguished, have been progressively reduced in numbers by imported disease and by economic dislocation. Large areas of the state's territory are uninhabited. Almost half of the population is concentrated in Manaus.

The language of Amazonas is Portuguese, but the local vocabulary also incorporates many words from the Indian languages. Roman Catholicism is the dominant religion, though the Indians have preserved elements of their original religions. Yellow fever, malaria, leprosy, and other tropical diseases occur sporadically.

The University of the Amazon, at Manaus, was founded in 1962. The National Research Institute for Amazonia, with its headquarters in Manaus, conducts research on Amazonian ecology.

The products of the state's vegetation—rubber, Brazil nuts, timber, guarana (a climbing shrub containing tannin and caffeine), vegetable oils, and fibres—form the basis of the economy. Cassava, jute, sugarcane, bananas, and sweet potatoes are grown on the belts of land fertilized annually by the rivers. Cattle have been introduced to the higher lands through government assistance programs that promote large-scale cattle ranching. Brazilian industry absorbs most of the raw materials produced by Amazonas, but rubber, timber, jute, vegetable oils, nuts, resins, aquarium fishes, and skins are exported.

Transport is mainly by water; the rivers accommodate both large ships and canoes. The Transamazônica highway, however, runs from east to west and connects the Atlantic coast, near Recife, with the Peruvian border. Area 605,390 square miles (1,567,954 square km). Pop. (2000 prelim.) 2,840,889.

Amazonas, *departamento*, southeastern Colombia, located in the warm, humid Amazon River basin. It is bounded on the northwest by the Caquetá River, on the northeast by the Apaporis River, on the east by Brazil, and on the south by Peru and the Putumayo River. Colombia's only direct contact with the Amazon River is through Amazonas. It is the largest *departamento* in Colombia but is also one of the least densely populated. Principal economic activities are the procurement of mahogany and other woods, rubber, and ipecac from the forests; fishing; and the cultivation of peanuts (groundnuts), bananas, pineapples and other fruits, rice, and sugarcane. Most of the population lives in and around Leticia (*q.v.*), the capital and major trade centre. No good roads penetrate the rain forest; travel is entirely by river or by air. Area 42,342 square miles (109,665 square km). Pop. (1997 est.) 60,251.

Amazonas, *departamento* (formed 1832), Nor Oriental del Marañón *región*, northern Peru, bounded on the north by Ecuador. It consists mostly of rain forest in the north, while in the south the Marañón River and its tributaries dissect the Cordillera Central. The Marañón forms part of the western boundary

with Cajamarca *departamento* before flowing northeastward into the Amazon River basin. The density of the largely rural population is low, with most settlements in the south. Chachapoyas (*q.v.*), the capital, is accessible by air and by road. Paved highways connect Amazonas with San Martín *departamento* to the east and Cajamarca to the west. Sugarcane, corn (maize), rice, potatoes, cotton, and cereals are grown, mainly in the south. Area 15,154 square miles (39,249 square km). Pop. (1998 est.) 391,078.

Amazonas, *estado* ("state"), southern Venezuela. It is bounded on the north by the state of Bolívar, on the east and south by Brazil, and on the west by Colombia. The large but sparsely populated state lies within the drainage basins of the Orinoco River, which rises near the Brazilian border, and the Negro River, which is a northern tributary of the Amazon. Near the centre of the territory is a maze of intricate natural channels. One stretch of 204 miles (328 km), the Casiquiare, flows south from the Orinoco; it is usually navigable by small boats for half the year and links the Orinoco with the Negro and, thus, the Amazon. Amazonas also includes the western outliers of the Guiana Highlands. Largely unexplored, the state consists mainly of hot, humid rain forest, with much tropical savanna. About two-thirds of the inhabitants are forest-dwelling Indians who hunt and fish for food, mainly on a subsistence basis. Puerto Ayacucho (*q.v.*), the state capital, lies on the Orinoco, just below rapids that block continuous navigation of the river. The economy is based principally on the gathering of rubber, balata, vanilla, and chicle. Transportation is mainly by boat, airplane, and dugout canoe. Area 67,900 square miles (175,750 square km). Pop. (1994 est.) 65,252.

amazonstone, also called AMAZONITE, a gemstone variety of green microcline (*q.v.*), a feldspar mineral. Frequently confused with jade, amazonstone varies in colour from yellow-green to blue-green and may also exhibit fine white streaks; it is usually opaque and therefore is cut en cabochon (with a rounded and convex polished surface). Although its name is derived from the Amazon River, no deposits have been found there. Amazonstone has been mined in Minas Gerais, Brazil; Ontario and Quebec, Canada; Baveno, Italy; and the Ural Mountains of Russia. The Pikes Peak district of Colorado, U.S., became the most important source of amazonstone after 1876; when samples were unveiled at the Centennial Exhibition, their impressive purity and size eventually forced competing Russian mineral dealers out of business.

Amb, small frontier state, central North-West Frontier Province, Pakistan. It became part of Pakistan in 1947 and lies on the west bank of the Indus River, 15 miles (24 km) north of the Tarbela Dam and northwest of Abbottābād. Apart from Amb, the main township, the state now consists of only three villages. The residence of the ruler (nawab), formerly at Amb, is now at Darband. The state is mainly agricultural, with wheat, barley, and corn (maize) the chief crops. Area 27 square miles (70 square km).

Ambāla, also called UMBALA, city, northeastern Haryāna state, northwestern India, just east of the Ghaggar River. A major grain, cotton, and sugar trade centre, it is connected by road and rail with Delhi and Amritsar (Punjab state). Other rail lines run northward to Simla and Kālka and southeastward to Sahāranpur. The city is also served by Ambāla Airport. One of India's largest military cantonments, which also houses a commercial centre and an airfield, lies 4 miles (6.5 km) southeast.

Economically important industries include cotton ginning, flour milling, food processing, and various manufactures. Cloth weaving and bamboo-furniture making are important handicrafts. Constituted a municipality in 1867, the city and cantonment have a hospital, a government metalworks institute, and several colleges affiliated with Kurukshetra University. The surrounding area is composed predominantly of a fertile alluvial plain. There is some canal irrigation, and grains, gram (chickpea), cotton, sugarcane, peanuts (groundnuts), and mangoes are the chief crops. Pop. (1991) 119,338.

Ambartsumian, Viktor Amasaspovich (b. Sept. 5 [Sept. 18, New Style], 1908, Tbilisi, Georgia, Russian Empire—d. Aug. 12, 1996, Byurakan Observatory, near Yerevan, Arm.). Soviet astronomer and astrophysicist best known for his theories concerning the origin and evolution of stars and stellar systems. He was also the founder of the school of theoretical astrophysics in the Soviet Union.

Ambartsumian was born of Armenian parents. His father, a prominent philologist, encouraged the development of his aptitude for mathematics and physics. In 1925 he entered the University of Leningrad (now Saint Petersburg State University) with the intention of devoting his life to research in astrophysics, and in the following year he published a paper on solar activity, the first of 10 papers

Ambartsumian, 1970

Tass—Sovfoto

he published while an undergraduate. After graduating in 1928, Ambartsumian became a graduate student in astrophysics under the direction of A.A. Belopolskii at Pulkovo Observatory near Leningrad (now St. Petersburg).

From 1931 to 1943 he lectured at the University of Leningrad, where he headed the Astrophysical Department. In 1932 he advanced his theory of the interaction of ultraviolet radiation from hot stars with the surrounding gas, a theory that led to a series of papers on the physics of gaseous clouds. His statistical analysis of stellar systems in 1934–36, in which for the first time their physical properties were taken into account, was found to be applicable to many related problems, such as the evolution of double stars and star clusters. He was elected a corresponding member of the Academy of Sciences of the U.S.S.R. in 1939 and was appointed a deputy rector of the University of Leningrad in 1941–43. His theory of the behaviour of light in a scattering medium of cosmic space, put forward in 1941–43, became an important tool in geophysics, space research, and particularly astrophysics, such as in studies of interstellar matter.

In 1943 Ambartsumian joined the Armenian Academy of Sciences in Yerevan, the capital of Armenia, and began teaching at Yerevan State University. In 1946 he organized the

construction near Yerevan of the Byurakan Astronomical Observatory, where he began another successful period of activity as the observatory's director. In 1947 he discovered a new type of comparatively recent stellar system, which he named stellar association. The most important result of his study is the conclusion that the process of star formation in the Milky Way Galaxy that contains the Sun and its planetary system still continues and, specifically, that most stars have their origin in changing systems of groups of stars.

Later, Ambartsumian studied the phenomena in the atmosphere of stars that are changing in physical characteristics, such as luminosity, mass, or density. He saw these changes as being connected with the direct release of interstellar energy in the outer layers of the stars. He also investigated nonstationary processes in galaxies. These investigations are of great importance, both for the problem of the evolution of galaxies and for the study of still-unknown properties of matter.

His textbook *Theoretical Astrophysics* (1958) went through many editions and translations. It contains examples of his unique and fruitful approaches to stubborn astronomical problems. In addition, he studied radio signals coming from outside the Milky Way Galaxy. He was led to conclude that these radio signals represent not colliding systems of stars, as according to a widely accepted interpretation, but the subatomic process of fission within galaxies. Therefore, according to his view, "radio galaxies" may represent systems of stars, interacting in close proximity, that were formed from superdense formations of stellar material. In support of this view, he pointed out the presence of jets, condensations, and streamers that are bluish in colour; found around certain galaxies, these are characteristics of an early stage in stellar development. Ambartsumian's later works include *Problemy sovremennoi kosmogonii* (1969; "Problems of Modern Cosmogony") and *Filosofskie voprosy nauki o Vselenoi* (1973; "Philosophical Problems of the Study of the Universe").

Ambartsumian's thought-provoking manner of presentation drew large audiences to his lectures at international symposia, where he enlivened even his most abstrusely mathematical lectures with quotations from classic and contemporary poets.

The Soviet government presented many decorations and awards to Ambartsumian. In 1947 he was elected president of the Armenian S.S.R. Academy of Sciences and a member of the Parliament of Soviet Armenia, and from 1950 he served in the Supreme Soviet of the U.S.S.R. In 1953 he was elected to full membership in the Academy of Sciences of the U.S.S.R. In 1948–56 he was vice president, and in 1961–63 president, of the International Astronomical Union. In 1968 he became president of the International Council of Scientific Unions, and he participated in activities of many foreign academies and scientific societies. He was awarded two Stalin prizes and five Orders of Lenin, among many other honours. He continued to head the Byurakan Observatory until 1988. (A.G.Ma.)

ambassador, highest rank of diplomatic representative sent by one national government to another.

At the Congress of Vienna in 1815, ambassadors were one of the four classes of diplomatic agents who were formally defined and recognized. Ambassadors were deemed to represent the person and dignity of the sovereign (or head of state) and were entitled to personal access to the sovereign to whom they were accredited. The Vienna Convention on Diplomatic Relations (1961) reduced to three the categories of diplomatic representatives, which are: (1) ambassadors and other heads of mission of equivalent rank who are accredited to the host heads of state; (2) envoys extraor-

inary, ministers plenipotentiary, and other representatives who are accredited to the host heads of state; and (3) *chargés d'affaires*, who are accredited to the foreign minister of the host country. The category of ministers-resident was omitted.

Ambassadors were originally exchanged only between the principal monarchies, with envoys or *chargés d'affaires* sufficing for the conduct of relations with less powerful states. Ambassadors were later also sent to republics regarded as being of equal rank. The United States appointed its first ambassadors in 1893. In 1914 there was a general exchange of ambassadors among the great powers—Austria-Hungary, France, Germany, Great Britain, Italy, Japan, Russia, and the United States—along with Spain and Turkey. Between 1919 and 1939 Belgium, China, Poland, and Portugal were raised to ambassadorial status, and since 1945, in accordance with the doctrine of the formal, legal equality of all states, most governments have sent representatives of ambassadorial rank to all countries to which they have extended diplomatic recognition.

Prior to the development of modern communications, ambassadors were frequently entrusted with extensive, even plenary, powers. They have since tended, however, to become spokesmen of their foreign offices, and rarely does an ambassador enjoy extensive discretion. An ambassador's personality and prestige, on the other hand, may play an important part in making the views of his government understood, and his firsthand knowledge of the country to which he is accredited may enable him to influence his government's policy decisively. *See also* extraterritoriality.

Ambato, city, central Ecuador. It lies along the Ambato River in an intermontane basin near the northeastern foot of Mount Chimborazo, at an elevation of about 8,500 feet (2,600 m) above sea level. It was the scene of a decisive victory in 1821 by Antonio José de Sucre, lieutenant of the liberator Simón Bolívar, against the Spanish during the

The cathedral (built mid-20th century), Ambato, Ecuador

Shostal

wars for Latin-American independence. Ambato has frequently been damaged by volcanic eruptions and earthquakes, and much of the city was destroyed by an earthquake in 1949. Its remaining landmarks include a modern cathedral and the mausoleum of Juan Montalvo, a noted Ecuadorian writer and freedom fighter, who was born in Ambato in 1832.

The city is an agricultural-trade centre; the Ambato River basin is noted for fresh fruits. There are also sugarcane plantations and grain farms in the locality. Industrial activity in-

cludes tanneries, leatherworks, food processing, and textile milling.

An important communications centre, Ambato is located on the Guayaquil-Quito railway line and on the Pan-American Highway. A road from the city leads over the eastern cordillera of the Andes via Baños to El Oriente region, the sparsely settled lowland jungle area of eastern Ecuador. Ambato's lush suburb of Miraflores is a favourite resort for the upper classes of Guayaquil. Pop. (2000 est.) 174,000.

Ambedkar, Bhimrao Ramji (b. April 14, 1891, Mhow, India—d. Dec. 6, 1956, New Delhi), leader of the Harijans (untouchables or low-caste Hindus) and law minister of the government of India (1947–51).

Born of an untouchable Mahar family of western India, he was as a boy humiliated by his high-caste schoolfellows. His father was an officer in the Indian Army. Awarded a scholarship by the Gaekwar (the ruler) of Baroda, he studied at universities in the United States, Britain, and Germany. He entered the Baroda Public Service at the Gaekwar's request, but, again ill-treated by his high-caste colleagues, he turned to legal practice and teaching. He soon established his leadership among Harijans, founded several journals on their behalf, and succeeded in obtaining special representation for them in the legislative councils of the government. Contesting Mahatma Gandhi's claim to speak for Harijans, he wrote *What Congress and Gandhi Have Done to the Untouchables* (1945).

In 1947 Ambedkar became the law minister of the government of India. He took a leading part in the framing of the Indian constitution, outlawing discrimination against untouchables, and skillfully helped to steer it through the assembly. He resigned in 1951, disappointed at his lack of influence in the government. In October 1956, finally in despair because of the perpetuation of untouchability in Hindu doctrine, he renounced Hinduism and became a Buddhist, together with about 200,000 fellow untouchables, at a ceremony in Nāgpur, India.

Amber (India): see *Āmer*.

amber, fossil tree resin that has achieved a stable state through loss of volatile constituents and chemical change after burial in the ground. Amber has been found throughout the world, but the largest and most significant deposits occur along the shores of the Baltic Sea in sands 40,000,000 to 60,000,000 years old.

Amber occurs as irregular nodules, rods, or droplike shapes in all shades of yellow with nuances of orange, brown, and, rarely, red. Milky-white opaque varieties are called bone amber. The turbidity of some amber is caused by inclusions of many minute air bubbles. Many hundreds of species of fossil insects and plants are found as inclusions. Deeply coloured translucent to transparent amber is prized as gem material.

Modern investigative techniques are directed toward isolating and identifying as many as possible of the individual resin components and, ultimately, to establishing a genetic relationship between fossil resins and modern resin-producing trees. By means of infrared spectroscopy, Mexican (Chiapas) amber has been shown to be related to a modern leguminous tree, *Hymenaea*. Though in the past amber was believed to be completely amorphous, subsequent X-ray diffraction studies have revealed crystalline components in some fossil resins.

Ornamental carved objects, beads, rosaries, cigarette holders, and pipe mouthpieces are made from amber. Amberoid, or "pressed amber," is produced by fusing together small pieces of amber under pressure. Parallel bands, or flow structure, in amberoid help to

Sphecomyrma freyi, primitive wasp-like ant in amber from New Jersey, Cretaceous Period, c. 100,000,000 years old; in the Museum of Comparative Zoology, Harvard University

distinguish it from natural amber. Despite the introduction of numerous synthetic substitutes, the beauty of the real material has remained unexcelled.

Amber Valley, district, administrative and historic county of Derbyshire, England. It lies in the East Midlands region to the north of the city and unitary authority of Derby. The district takes its name from the River Amber, which joins the River Derwent at Ambergate. The industrial eastern half of the district contrasts with the still rural western portion. Traditionally coal mining and ironworking were the staple economic activities, but from the late 1950s there was considerable industrial diversification after mining began to decline in importance. Some of the derelict mining land has been reclaimed, and new industrial estates have been built on it, notably near Alfreton. Engineering is important at Ripley and Belper, which is also a centre of cotton and hosiery manufacturing. Jedediah Strutt, inventor of a stocking ribbing machine, built the town's first cotton mill in 1776. Among buildings of interest are the picturesque remains of Wingfield Manor House, begun in 1440 and dismantled in 1646. Area 102 square miles (264 square km). Pop. (2001) 116,475.

Amberes, Gil de: see *Silóé, Gil de*.

Amberg, city, Bayern Land (Bavaria state), southeastern Germany, on the Vils River, in the foothills of the Franconian Jura and Bayernwald (Bavarian Forest), southeast of Nürnberg. First mentioned in 1034, it was a court town with considerable trade (in iron and tinsplate) and industry in the 14th–16th century. The ducal residence (until 1621) and the cap-

ital (until 1810) of the Upper Palatinate, it had many trading and shipping privileges and was considered one of the strongest fortified towns in medieval Germany. The old walls and town gates still stand. In 1796 the Austrians under Archduke Charles decisively defeated the French under Gen. (later Marshal) Jean-Baptiste Jourdan there; the battle is recorded on the Arc de Triomphe in Paris. The 15th-century town hall, the ducal castle, and the electoral palace are among many surviving medieval and Baroque buildings. St. Martin's Church (1421), St. George's (14th century, transformed into Baroque in the 18th century), and the pilgrimage church (1697–1702) on the Mariahilberg are also notable. The state archives for the Upper Palatinate as well as the municipal archives are in Amberg, and there is a fine provincial library (founded 1730). Amberg's diversified industries include iron-ore mining and working, glass grinding, enamelling, porcelain and brick works and breweries. Pop. (1998 est.) 43,168.

ambergris, solid substance formed in the intestine of the sperm whale (*Physeter catodon*). It is used chiefly as a spice in the East, and in the West it was once used to fix the scent of fine perfumes. Ambergris is thought to be a substance that protects the whale's intestines from being irritated by the indigestible horny beaks of squid and cuttlefish. It is not definitely known whether the process is normal or pathological. Ambergris, when fresh, is soft and black and has a disagreeable odour. When exposed to sun, air, and seawater, it hardens, fades, and develops a pleasant scent. It washes ashore in many countries, and it has also been found in the bodies of whales or floating free on the sea. Pieces are usually small, but one find weighed about 635 kg (1,400 pounds).

amberina glass, blended colour glass in which the lower part, a yellowish amber, merges into a ruby-red colour higher in the vessel. It was patented in 1883 for the New England Glass Company at East Cambridge, Mass., and was produced extensively there and by the successor company, the Libbey Glass Company at Toledo, Ohio, into the 1890s. The base metal was an amber glass containing some gold, and the tinges were developed by applied reheating. The glass was sometimes blown in molds. A wide range of table and ornamental wares, with diamond or ogival designs, or swirled ribbing, were produced by the New England Glass Company, and amberina glass was also produced at New Bedford, Mass., under the name rose amber.

amberjack, any of several popular sport fishes. See *jack*.

Ambikāpur, formerly SURGUJA, also called BISRĀMPUR, town, eastern Madhya Pradesh state, central India. The town, then known as Surguja, was the capital of the former Surguja princely state. Connected by road with Dharmjaygarh, Patna, and Sonhāt, it is heavily engaged in agricultural trade and is a major coal collection and distribution centre.

The surrounding region once consisted of the princely states of Surguja, Changbhakar, and Koria. It is a fertile central plateau surrounded on the north, east, and south by massive hill barriers and tablelands. Rice, wheat, and oilseeds are the chief agricultural products of the region around Ambikāpur. Forest products are also economically significant. Pop. (1991) town, 50,277; metropolitan area, 53,227.

Ambler, Eric (b. June 28, 1909, London, Eng.—d. Oct. 22, 1998, London), British author and screenwriter widely regarded as one of the most distinguished writers of espionage and crime stories.

The son of music-hall entertainers, Ambler studied engineering at London University, but he was employed as an advertising writer when he completed his first novel, *The Dark Frontier* (1936). His early novels, set in continental Europe, were permeated with the emotional atmosphere of the impending world war. His intricate plots and growing skill at creating vivid characterizations culminated in *The Mask of Dimitrios* (1939; also published as *A Coffin for Dimitrios*) and *Journey into Fear* (1940), both later made into memorable films.

Following service in World War II writing training films for the British Army, Ambler wrote screenplays. With Charles Rodda he wrote novels under the joint pseudonym Eliot Reed. His first postwar book under his own name, *Judgment on Delchev* (1951), was set in the Balkans. His later novels included *The Light of Day* (1962), *The Levanter* (1972), and *The Care of Time* (1981).

In contrast to earlier British spy stories, in which xenophobic, romantic heroes defeated vast conspiracies to dominate the world, Ambler's tales were of ordinary, educated Englishmen thrust by chance or curiosity into danger. Notable for its gritty realism, Ambler's fiction was a major influence on writers such as Graham Greene and John Le Carré.

amblygonite, phosphate mineral, composed of lithium, sodium, and aluminum phosphate [(Li,Na)AlPO₄(F,OH)], that is an ore of lithium. It occurs in lithium- and phosphate-rich granitic pegmatites, often in very large, white, translucent masses. It has been mined at Keystone, S.D., and in South Africa, Zimbabwe, and several other countries. Clear material from Hebron, Maine, has been faceted as a gemstone. For detailed physical properties, see phosphate mineral (table).

Montebrasite, a similar mineral, contains more hydroxide than fluoride ion; in nature there is a continuous chemical variation, called a solid-solution series, between montebrasite and amblygonite.

amblyopia, reduced vision caused by abnormal visual experience in early childhood, leading to the improper development of the nerves connecting the eye and the visual centres of the brain. The condition usually occurs in one eye, although it may occur in both. The brain receives weak or distorted images from the affected eye so that the brain begins to favour visual information from the stronger eye. Amblyopia may result from strabismus (crossed eyes), farsightedness, nearsightedness, or congenital cataracts. Treatment is directed towards the underlying problem and may include surgery, eyeglasses, or the placement of a patch over the stronger eye to encourage the use of the

other. If left untreated, amblyopia may lead to irreversible vision deficits, including blindness.

Ambo, also called OVAMBO, ethnolinguistic group located in the dry grassland country of northern Namibia and southern Angola. They are usually called Ovambo in Namibia and Ambo in Angola and speak Kwanyama, a Bantu language. The Ambo were originally ruled by hereditary kings who performed priestly functions.

The Ambo economy rests almost equally on agriculture and animal husbandry, supplemented by fishing, hunting, and gathering. Millet and sorghum are the most extensively cultivated crops; cattle, sheep, and goats are owned by all of the groups, cattle being of particular importance for marriage payments, as well as for milk and butter.

Despite their small number, traditional Ambo groups exhibited typical characteristics of African centralized states: the above-mentioned priest-king, official tax collectors, a queen mother of great prestige, a hereditary aristocracy, and slaves.

Descent is matrilineal, and polygyny is practiced. The first wife enjoys seniority, but each has her own hut, a circular structure of wattle and daub with a thatched, conical roof. Family compounds, which contain only a nuclear family (parents and dependent children), are grouped around a central meeting place, in which is found a chief's hut or a council house containing a sacred fire tended by the principal wife or daughter of the local chief. It cannot be used for cooking (except for the meal of a departing warrior) or for warmth; it is a symbol of the community, and its extinction is regarded as an omen of impending destruction. Local chiefs and headmen light their sacred fires from those of their superiors.

ambo, in the Christian liturgy, a raised stand formerly used for reading the Gospel or the Epistle, first used in early basilicas. Originally, the ambo took the form of a portable lectern. By the 6th century it had evolved into a stationary church furnishing, which reflected the development and codification of the Christian liturgy. By the Byzantine and early Romanesque periods, it had become an essential part of the church plan. In the 12th century, the ambo was gradually superseded by the pulpit, and it passed out of liturgical use.

The ambo had either a single or a double construction, and its position in the Latin-cross church plan was not absolutely uniform. Its position varied in the plan of Eastern religious buildings. In Russian Orthodox churches, for instance, the ambo took the form of steps leading to a platform in front of the iconostasis (*q.v.*). In the Greek Orthodox church it retained its earlier movable form and was placed at one side. The Byzantine rite of the Catholic church merely used a table set before the doors of the iconostasis.

The typical single ambo consisted of raised platforms on three levels reached by steps and protected by railings. Each level was consecrated to a special part of the service.

By at least the 11th century, double ambos appeared and were normally placed on either side of the choir, with the north ambo used for the reading of the Epistle and the south for the Gospel. Ambos in richly decorated churches were often made of marble and sometimes decorated with mosaics or carving.

Amboina (Indonesia): see Ambon.

Amboina Massacre, execution that took place in Amboina (now Ambon, Indon.) in 1623, when 10 Englishmen, 10 Japanese, and one Portuguese were put to death by local Dutch authorities. The incident ended any hope of Anglo-Dutch cooperation in the area, a goal that both governments had been pursuing for several years, and marked the beginning of Dutch ascendancy in the Indies.

During the first quarter of the 17th century

the Dutch East India Company had already established itself in Amboina, one of the Spice Islands (Maluku, formerly Moluccas). A Dutch garrison was stationed in Fort Victoria and a local Dutch governor was appointed. The English merchants associated with the British East India Company, however, were also attracted to the island, and their interests eventually came into conflict with those of the Dutch. Early in 1623 the Dutch local governor, Herman van Speult, believed that the English merchants, helped by Japanese mercenaries, planned to kill him and overwhelm the Dutch garrison as soon as an English ship arrived to support them. He then ordered the arrest of the alleged plotters. Under torture they admitted their guilt and were found guilty by the court of Amboina and executed in February 1623. The term *massacre* was applied to this incident by the English.

Amboise, town, Indre-et-Loire *département*, Centre *région*, central France, on both banks of the Loire River, east of Tours. It is the site of a late Gothic château (with Renaissance additions), one of a great company of castles in the rich, rolling Loire country.

The town was first mentioned in 504 as Ambatia, when on the isle of Saint-Jean (now Île d'Or), Clovis, king of the Franks, met Alaric II, king of the Visigoths, to make a short-lived pact. In the 11th century Fulk III Nerra, count of Anjou, took the town from the count of Blois and built a high, square stone keep, from which the present château emerged. Thrusting up from a rock above the river, the château has a three-story facade flanked by two enormous squat towers. It was a favourite

photograph, Knecht

residence of French monarchs from the mid-15th century to the 17th. Charles VIII, who was born and died there, brought artists from Italy to embellish the place.

Huguenot efforts to remove Francis II from the influence of the House of Guise were exposed in 1560 as the Conspiracy of Amboise, and subsequently Protestant corpses hung from the balcony of the king's house, a Gothic portion of the château. Nevertheless, the Édict d'Amboise (1563) granted freedom of worship to Protestant nobility and gentry. From the time of Henry IV, the château was often used as a prison, and Abdelkader, the Algerian national leader, was confined there (1848–52). In 1872, after private owners had razed portions of the château, the National Assembly voted its return to the Orléans family.

In the town itself the 16th-century town hall is a museum. The Porte de l'Horloge is a 15th-century gateway with a carillon. To the south-east is Le Clos-Lucé, formerly the castle of Cloux, where Leonardo da Vinci died; it is now a museum. Immediately south is the seventeenth-century Pagoda of Chanteloup, a piece of 18th-century chinoiserie. Industrial development has extended there from Paris and includes the

manufacture of machine tools, chemical products, and shoes. Pop. (1999) 23,068.

Amboise, Conspiracy of, abortive plot of young French Huguenot aristocrats in 1560 against the Catholic House of Guise.

On the accession of the 14-year-old Francis II to the French throne in 1559, the Guise family gained ascendancy in the government, creating enmity among the smaller nobility. A conspiracy to overturn their government was formed at Nantes, with a needy Périgord nobleman named La Renaudie as its nominal head, though the agitation had in the first instance been fostered by the agents of Louis I de Bourbon, prince de Condé. The Guises were warned of the conspiracy while the court was at Blois, and for greater security they removed the King to Amboise. La Renaudie, however, merely postponed his plans, and the conspirators assembled in small parties in the woods around Amboise. They had, however, been again betrayed, and many of them were surrounded and captured before the coup could be delivered; on March 19, 1560, La Renaudie and the rest of the conspirators openly attacked the château of Amboise. They were repelled, La Renaudie was killed, and a large number were taken prisoners.

The Guises exercised merciless vengeance. For a week the torturings, quarterings, and hangings went on, the bodies being cast into the Loire. The Guises further convened a special commission to try Condé, who was condemned to death; but the affair was postponed by the chancellor, and the death of Francis II in December saved Condé.

Amboise, Georges d' (b. 1460, Chaumont-sur-Loire, Fr.—d. May 25, 1510, Lyon), cardinal and chief minister of the French state under King Louis XII, known for his domestic reforms and his role in Louis's Italian campaigns.

Son of Pierre d'Amboise, who was chamberlain to Charles VII and Louis XI and ambassador to Rome, Georges received the bishopric of Montauban when only 14, and was appointed an almoner of Louis XI. Later, under Charles VIII, he was imprisoned as a follower of the Duc d'Orléans, the future Louis XII. When the Duc d'Orléans was restored to favour, d'Amboise received the archbishoprics of Narbonne (1492) and Rouen (1493) and was made lieutenant general of Normandy. When Orléans became king in 1498, d'Amboise became a cardinal and first minister of the crown.

D'Amboise reduced administrative spending and thus was able to reduce taxes; he also instituted important judicial reforms. He did much for the organization of Louis XII's expedition against Milan (begun 1499). When Pope Alexander VI died in 1503, d'Amboise hoped to become pope but refused to use French troops to force his election. An Italian

was chosen as Pius III, and, on his death a month later, another Italian was chosen as Julius II. As compensation, Cardinal d'Amboise was made legate for life to France and to the Comtat-Venaissin. Remaining active in the French government, he was one of the negotiators of the Treaty of Blois (1504) with the emperor Maximilian I, and of the League of Cambrai against Venice. His death occurred on his return from another venture into Italy with Louis XII.

Amboise, Jacques d': see d'Amboise, Jacques.

Ambon, formerly AMBOINA or AMBOYNA, island and municipality of Maluku *propinsi* (province), Indonesia. Ambon island is located 7 mi (11 km) off the southwestern coast of the island of Seram. Its 294 sq mi (761 sq km) are generally hilly, with Mt. Salhatu rising to 3,405 ft (1,038 m). Although subject to earthquakes, Ambon has no active volcanoes, but it does have some hot springs and hot-gas vents, or solfataras. It has a tropical climate with an abundant rainfall. The hard and knotty Ambon wood, of great value for ornamental woodwork, is obtained from Seram. There are few mammals indigenous to Ambon, but birds include a racket-tailed kingfisher, a crimson lory, and a vivid crimson brush-tongued parrot. Many varieties of fish live in Teluk (bay) Ambon, whose eastern end contains some marine gardens.

Ambon's clove trade first attracted the Portuguese, who named the island and founded a

Zebras in the Amboseli National Park, Kenya
John Lewis Stage—Photo Researchers

settlement in 1521. The Dutch captured the Portuguese fort in 1605, took over the spice trade, and in 1623 destroyed a British settlement in the Amboina Massacre. The British took it in 1796, and after it had exchanged hands twice between the British and Dutch, it was restored finally to the latter in 1814. An important naval base, Ambon was occupied by Japan during World War II. In 1950, after Indonesian independence, the Ambonese—many of whom had been educated in Christian schools and served in the Dutch administration and army—found their new social and economic prospects unpromising; they refused to join the unitary Republic of Indonesia and proclaimed an independent South Moluccan Republic. The movement was suppressed by military action, though guerrilla warfare continued in Seram for over a decade, and many Ambonese fled to The Netherlands.

The Ambonese are mainly Melanesian; they also live in the Uliasers and on the nearby Seram coast. The Muslims generally live in the north, and the Christians, in the majority and overwhelmingly Protestant, the south. The language, related to Timorese, serves as a regional lingua franca: it is of the Indonesian family, with many Portuguese and Dutch loanwords.

Agricultural production, generally insignificant, includes corn (maize), coffee, root crops, sago, and cloves. Copra, sugar, and fish are exported, and palm wine is made. Ambon's port is the chief centre for shipment of produce and for distribution of imports. The island has ad-

equate local roads, a government radio station, a telephone system, and Pattimura airport (on the western side of the harbour). Cultural amenities include Universitas Pattimura Ambon (1956), a religious college, and a museum.

The port city of Ambon, on Laitimor Peninsula on the eastern side of the bay, is about 8 mi from the harbour's outer entrance. The capital of Maluku province, it was known under the Dutch for its wide, tree-lined streets; stone houses; and imposing public buildings, including a hospital, a church dating from earliest settlement, and Ft. Victoria, built in the early 17th century and later restored. Much of this, including government buildings and barracks, was destroyed in World War II and the following years. Since 1999, fighting between Christians and Muslims on Ambon has produced a mass exodus of Muslims, primarily to Buton in Sulawesi, and an influx of Christians fleeing conflict in other parts of Central Maluku, such as Seram, Buru, and Sula islands. Pop. (2000) city, 312,100; island (including adjacent islands), 880,200.

Amboseli National Park, formerly MASAI AMBOSELI GAME RESERVE, national park, southern Kenya, East Africa. Amboseli was originally established as a game reserve in 1948 and covered 1,259 sq mi (3,261 sq km),

northwest of Kilimanjaro in Tanzania. Within it were distinguished seven habitats: open plains, acacia woodland, lava-strewn thorn-bush country, swamp, marshland, the Amboseli lake bed, and the slopes of Oldoinyo Orok. The reserve was also occupied by the Masai and their herds.

In 1974 a little more than 10 percent of the Reserve was established as the Amboseli National Park, with an area of 151 sq mi (392 sq km). Centred on Lake Amboseli, normally dry with a flat basin of alkaline soils, the park encompasses three of the original seven habitats: open plains, thorn-bush country, and acacia woodland. A great variety of wildlife inhabits the park. Important fauna include the baboon, lion, cheetah, elephant, black rhinoceros, hippopotamus, Masai giraffe, buffalo, oryx, wildebeest, gerenuk, impala, and gazelle.

Ambridge, borough, Beaver County, western Pennsylvania, U.S., on the Ohio River, just northwest of Pittsburgh. Within its boundaries is the former village of Economy (1825–1906) established by the communal Harmony Society, led by George Rapp. The Harmonists (Rappites) were religious immigrants from Württemberg, Ger., who had previously settled at Harmony, Pa., and New Harmony, Ind. The community prospered for about 50 years but declined because of the practice of celibacy and the lack of converts. In 1901 the American Bridge Company purchased 2,500 ac (1,012 ha) and established a town, which was incorporated as a borough in 1905 and

D'Amboise, detail of an engraving by an unknown artist
By courtesy of the Bibliothèque Nationale, Paris

renamed Ambridge in 1906. The state of Pennsylvania purchased (1919) many of the original Rappite buildings, which have been restored as the historical village of Old Economy. In addition to the bridge works, manufactures include wrought iron, pipe, electrical equipment, and building materials. Pop. (1990) 8,133.

Ambrim (Vanuatu): see *Ambrym*.

Ambrogini, Angelo (Renaissance scholar): see *Politian*.

Ambros, August Wilhelm (b. Nov. 17, 1816, Vysoké Mýto, near Prague—d. June 28, 1876, Vienna), musicologist, author of *Geschichte der Musik*, a comprehensive history of music.

Ambros studied law, entered the civil service in 1840, and became public prosecutor in Prague in 1850. A keen, well-trained musician and composer of a Czech opera, *Bretislav a Jitka*, he also established himself as a brilliant writer on music. His pamphlet *Über die Grenzen der Poesie und Musik* (1856) contributed to a heated aesthetic controversy. In 1869 he became professor of music at Prague and, in 1872, of music history at Vienna. His *Geschichte der Musik*, incomplete at his death, covered antiquity, the Middle Ages, and the Renaissance. Scholars completed the work from his notes.

Ambrose, SAINT, Latin *AMBROSIUS* (b. c. AD 339, Augusta Treverorum, Belgica, Gaul—d. 397, Milan; feast day December 7), bishop of Milan, biblical critic, and initiator of ideas that provided a model for medieval conceptions of church-state relations. His literary works have been acclaimed as masterpieces of Latin eloquence, and his musical accomplishments are

St. Ambrose, detail of a fresco by Pinturicchio, 1480s; in Sta. Maria del Popolo, Rome

Alinari—Art Resource/EB Inc

remembered in his hymns. Ambrose is also remembered as the teacher who converted and baptized St. Augustine of Hippo, the great Christian theologian, and as a model bishop who viewed the church as rising above the ruins of the Roman Empire.

Early career. Though Ambrose, the second son of the prefect (imperial viceroy) of Gaul, was born in the official residence at Augusta Treverorum (Trier), his father died soon afterward, and Ambrose was reared in Rome, in a palace frequented by the clergy, by his widowed mother and his elder sister Marcellina,

a nun. Duly promoted to the governorship of Aemilia-Liguria in c. 370, he lived at Milan and was unexpectedly acclaimed as their bishop by the people of the city in 374.

Ambrose, a popular outsider, chosen as a compromise candidate to avoid a disputed election, changed from an unbaptized layman to a bishop in eight days. Coming from a well-connected but obscure senatorial family, Ambrose could be ignored as a provincial governor; as bishop of Milan he was able to dominate the cultural and political life of his age.

Ecclesiastical administrative accomplishments. An imperial court frequently sat in Milan. In confrontations with this court, Ambrose showed a directness that combined the republican ideal of the prerogatives of a Roman senator with a sinister vein of demagoguery. In 384 he secured the rejection of an appeal for tolerance by pagan members of the Roman senate, whose spokesman, Quintus Aurelius Symmachus, was his relative (Letters 17, 18). In 385–386 he refused to surrender a church for the use of Arian heretics. In 388 he rebuked the emperor Theodosius for having punished a bishop who had burnt a Jewish synagogue. In 390 he imposed public penance on Theodosius for having punished a riot in Thessalonica by a massacre of its citizens. These unprecedented interventions were palliated by Ambrose's loyalty and resourcefulness as a diplomat, notably in 383 and 386 by his official visits to the usurper Maximus at Trier. In his letters and in his funeral orations on the emperors Valentinian II and Theodosius—*De obitu Valentiniani consolatio* (392) and *De obitu Theodosii* (395)—Ambrose established the medieval concept of a Christian emperor as a dutiful son of the church "serving under orders from Christ," and so subject to the advice and strictures of his bishop.

Literary and musical accomplishments. Ambrose's relations with the emperors formed only part of his commanding position among the lay governing class of Italy. He rapidly absorbed the most up-to-date Greek learning, Christian and pagan alike—notably the works of Philo, Origen, and St. Basil of Caesarea and of the pagan Neoplatonist Plotinus. This learning he used in sermons expounding the Bible and, especially, in defending the "spiritual" meaning of the Old Testament by erudite philosophical allegory—notably in the *Hexaëmeron* ("On the Six Days of Creation") and in sermons on the patriarchs (of which *De Isaac et anima* ["On Isaac and the Soul"] and *De bono mortis* ["On the Goodness of Death"]) betray a deep acquaintance with Neoplatonic mystical language). Sermons, the dating of which unfortunately remains uncertain, were Ambrose's main literary output. They were acclaimed as masterpieces of Latin eloquence, and they remain a quarry for students of the transmission of Greek philosophy and theology in the West. By such sermons Ambrose gained his most notable convert, Augustine, afterward bishop of Hippo in North Africa and destined, like Ambrose, to be revered as a doctor (teacher) of the church. Augustine went to Milan as a skeptical professor of rhetoric in 384; when he left, in 388, he had been baptized by Ambrose and was indebted to Ambrose's Catholic Neoplatonism, which provided a philosophical base that eventually transformed Christian theology.

Ambrose provided educated Latins with an impeccably classical version of Christianity. His work on the moral obligations of the clergy, *De officiis ministrorum* (386), is skillfully modelled on Cicero's *De officiis*. He sought to replace the heroes of Rome with Old Testament saints as models of behaviour for a Christianized aristocracy. By letters, visitations, and nominations he strengthened this aristocratic Christianity in the northern Italian towns that he had once ruled as a Roman governor.

In Milan, Ambrose "bewitched" the populace by introducing new Eastern melodies and by composing beautiful hymns, notably "Aeternae rerum Conditor" ("Framer of the earth and sky") and "Deus Creator omnium" ("Maker of all things, God most high"). He spared no pains in instructing candidates for Baptism. He denounced social abuses (notably in the sermons *De Nabuthe* ["On Naboth"]) and frequently secured pardon for condemned men. He advocated the most austere asceticism: noble families were reluctant to let their marriageable daughters attend the sermons in which he urged upon them the crowning virtue of virginity.

Evaluations and interpretations. Ambrose's reputation after his death was unchallenged. For Augustine, he was the model bishop: a biography was written in 412 by Paulinus, deacon of Milan, at Augustine's instigation. To Augustine's opponent, Pelagius, Ambrose was "the flower of Latin eloquence." Of his sermons, the *Expositio evangelii secundum Lucam* (390; "Exposition of the Gospel According to Luke") was widely circulated.

Yet, Ambrose is a Janus-like figure. He imposed his will on emperors. But he never considered himself as a precursor of a polity in which the church dominated the state: for he acted from a traditional fear that Christianity might yet be eclipsed by a pagan nobility and Catholicism uprooted in Milan by Arian courtiers. His attitude to the learning he used was similarly old-fashioned. Pagans and heretics, he said, "dyed their impieties in the vats of philosophy"; yet his sermons betray the pagan mysticism of Plotinus in its most un-muted tints. In a near-contemporary mosaic in the chapel of S. Satiro in the church of S. Ambrogio, Milan, Ambrose appears as he wished to be seen: a simple Christian bishop clasping the book of Gospels. Yet the manner in which he set about his duties as a bishop ensured that, to use his own image, the Catholic Church would rise "like a growing moon" above the ruins of the Roman Empire. (P.R.L.B.)

BIBLIOGRAPHY. *Collected editions.* The edition of the complete works given in J.P. Migne (ed.), *Patrologia Latina*, vol. 14–17 (1845), is gradually being superseded by that of the "Corpus Christianorum Series," *Sancti Ambrosii Mediolanensis Opera* (1957–). English translations of Ambrose's letters and various works are given in vol. 26, 42, and 44 (1954–63; reprinted with corrections, 1967), in the series "The Fathers of the Church."

Life. The contemporary biography, written by Ambrose's former secretary, Paulinus of Milan, was edited by Michele Pellegrino as Paolina de Milano, *Vita di S. Ambrogio* (1961). The most comprehensive biography is F. Homes-Dudden, *The Life and Times of St. Ambrose*, 2 vol. (1935). A shorter account is Angelo Paredi, *S. Ambrogio e la sua età*, 2nd ed. (1960); *Saint Ambrose: His Life and Times*, 1964). Ambrose's current position is dealt with in J.R. Palanque, *Saint Ambroise et l'Empire romain* (1933); his relation to Neoplatonism is considered in Pierre Courcelle, *Les Lettres grecques en Occident, de Macrobe à Cassiodore*, rev. ed. (1948; *Late Latin Writers and Their Greek Sources*, 1969).

Ambrose of Camaldoli, Italian *AMBROGIO CAMALDOLESE*, original name *AMBROGIO TRAVERSARI* (b. Sept. 16, 1386, Portico, Republic of Florence—d. Oct. 20, 1439, Florence), Humanist, ecclesiastic, and patristic translator who helped effect the brief reunion of the Eastern and Western churches in the 15th century. He entered the Camaldolese Order in 1400 at Florence, where, over a period of 30 years, he mastered Latin and particularly Greek, which enabled him to translate Greek patristic works into Latin, including those of SS. Athanasius the Great of Alexandria, Basil the Great of Caesarea, and John Chrysostom of Constantinople. His reputation in Humanist circles won him the patronage of Cosimo de' Medici.

Pope Eugenius IV appointed him minister

general of the Camaldolese Order in 1431 and papal emissary to the Council of Basel in 1435. He served a prime role at the Council of Ferrara–Florence when, in 1438, as papal representative, he received at the council the Byzantine emperor John VIII and Patriarch Joseph of Constantinople. His expertise in Greek and Eastern theology made him a chief negotiator for the decree of union between the Latin and Greek churches promulgated shortly before his death. Although never formally beatified, he is commemorated at Florence and by the Camaldolese on November 20.

Ambrosian chant, monophonic, or unison, chant that accompanies the Latin mass and canonical hours of the Ambrosian rite. The word Ambrosian is derived from St. Ambrose, bishop of Milan (374–397), from which comes the occasional designation of this rite as Milanese. Despite legends to the contrary, no Ambrosian-chant melodies can be attributed to Ambrose.

The Ambrosian Ordinary (chants of the mass having texts that do not change from day to day) has some relationship to the Roman Gregorian Ordinary (the standard Roman Catholic liturgy and chant): they each have a Kyrie and Gloria, except that the Kyrie is appended to the Ambrosian Gloria (in the Roman Ordinary it precedes the Gloria); each has a Credo (called Symbolum in the Ambrosian rite) and a Sanctus. For the breaking of the Communion breads, the Ambrosian rite uses the Confractorium, a Proper chant (one having a text that varies during the church year), whereas the Gregorian has the Agnus Dei, an Ordinary chant. The Ambrosian Ordinary chants are generally but not always syllabic (one note per syllable). The festive Gloria has expressive melismas (many notes per syllable) at the conclusion of syllabic phrases. Compared to the Gregorian rite, the Ambrosian has few Ordinary chants.

The late date of the Ambrosian-chant manuscripts (12th century) raises doubt concerning the time of the origin of this chant. It is thought that the Ambrosian chant was established and differed stylistically from Gregorian chant in the era of Charlemagne (d. 814), who unsuccessfully endeavoured to replace the Ambrosian with the Gregorian liturgy. Gregorian melodies and texts from this time and later are found integrated within the Ambrosian repertory. Ambrosian chants, however, also include a primitive body of less uniform and theoretically unorganized chants that remained apparently uninfluenced by the polished and systematized Gregorian repertory.

There are several traits native to the Ambrosian chants and not typically Gregorian. Unlike the Gregorian chants, the Ambrosian are not stylistically uniform for any liturgical category; e.g., Gregorian Tracts (a category of chant) have certain musical traits in common with each other, but no such consistencies appear among Ambrosian chants. The Ambrosian chants are not written in any mode (theoretical melodic and scale pattern), whereas a given Gregorian chant is in one of the eight church modes. The Ambrosian psalm tones (formulas for intoning psalms) differ from the Gregorian psalm tones in that the former have no middle cadence (stopping point) and have a greater choice of reciting tones and terminations. Representative of Oriental influence are the Ambrosian *melodiae* (freely interchangeable melismatic fragments) found in the responsories (a type of chant) for Matins (a service of the canonical hours).

Ambrosiaster, the name given to the author of a commentary on St. Paul's letters in the New Testament, long attributed to St. Ambrose (died 397), bishop of Milan. The work

is valuable for the criticism of the Latin text of the New Testament.

In 1527 Erasmus expressed doubts that the work was written by Ambrose. His judgment was eventually accepted by scholars, and the author is generally called Ambrosiaster or Pseudo-Ambrosius. Since Augustine in the 4th century attributed some parts of the commentary on Romans to Sanctus Hilarius, the work has been ascribed by various scholars to almost every known Hilary.

Ambrym, also spelled AMBRIM, island of Vanuatu, southwestern Pacific Ocean. It has an area of 257 sq mi (665 sq km) and is known for its two active volcanoes: Mt. Marum, 4,167 ft (1,270 m), which last erupted in 1973; and Mt. Benbow, 3,720 ft, which had major eruptions in 1894, 1913, 1929, 1942, 1950, 1972 and 1973. The 1950 eruption was serious enough to warrant the evacuation of several hundred persons for resettlement on Efaté. The island produces copra. Pop. (1989) 7,191.

ambulatory, in architecture, continuation of the aisled spaces on either side of the nave (central part of the church) around the apse (semicircular projection at the east end of the church) or chancel (east end of the church

Ambulatory, Saint-Benoît-sur-Loire, Fr., 11th century
Jean Roubier

where the main altar stands) to form a continuous processional way. The ambulatory often provided improved sites for the numerous altars for saints, which formerly were located along a crowded corridor behind the high altar; the altars are reached through circular arches piercing the curved outer wall of the ambulatory.

The first ambulatory was developed during the rebuilding of Saint-Martin at Tours in France (begun c. 1050, now destroyed). By the beginning of the 13th century the Benedictines had introduced the ambulatory to England, and many English cathedrals were extended eastward in this manner.

ambush bug, any member of the insect family Phymatidae (order Heteroptera), which contains about 200 species, generally in the tropical Americas and Asia. As its common name indicates, the ambush bug hides on a flower or plant; when prey approaches closely enough, the ambush bug grasps it with its front legs. The upper section (tibia) of each foreleg has teethlike structures that mesh into similar structures on the lower, greatly thickened leg section (femur). Holding its victim in these pincers, the ambush bug inserts its short beak and sucks out the body fluids. Even though the ambush bug is small (usually less than 12

millimetres, or 0.5 inch), its prey may be as large, comparatively, as a bumblebee, wasp, or butterfly.

The ambush bug has an odd shape, with lateral extensions and rounded projections. The Asian genus *Carcinocoris* is covered with

Ambush bug (Phymatidae)

Earl L. Kubis from Root Resources—EB Inc

spines. *Phymata erosa*, one of the most common North American representatives, is yellowish green and is usually found on goldenrod plants.

AMC: see American Motors Corporation.

Amda Tseyon (Amharic: Pillar of Zion) (d. 1344?), ruler of Ethiopia from 1314 to 1344, best known in the chronicles as a heroic fighter against the Muslims; he is sometimes considered to have been the founder of the Ethiopian state.

The earliest Ethiopian chronicle, which is more than simply a king list, tends to support this hypothesis, for it concerns Amda Tseyon's reign, and the earliest known examples of the written Amharic language are hymns praising him. His image is reminiscent of that of Henry V of England in his transformation from a youthful carouser to an audacious warrior and ruler. Most of his wars were against the Muslim kingdoms to the southeast, which he was able to fight and generally defeat one by one, despite their plans to unite against him. Hence, he substantially enlarged his kingdom by gradually incorporating a number of smaller states.

ameba, amebic, ameboid, etc.: see under amoeba, amoebic, amoeboid, etc.

Amédée (French personal name): see under Amadeus.

Amedeo (Italian personal name): see under Amadeus.

Ameghino, Florentino (b. Sept. 19, 1853, Moneglia, Kingdom of Sardinia—d. Aug. 6, 1911, La Plata, Arg.), paleontologist, anthropologist, and geologist, whose fossil discoveries on the Argentine Pampas rank with those made in the western United States during the late 19th century.

Ameghino's family immigrated to Argentina when he was a small child. He began collecting fossils as a youth and soon developed an interest in fossil classification. His first contributions were largely ignored by South American journals, but correspondence with French paleontologist and zoologist Paul Gervais, director of the *Journal de Zoologie*, led to international recognition. Altogether, he discovered more than 6,000 fossil species of extinct fauna. He was appointed professor of zoology at the University of Córdoba (1884) and professor of geology and mineralogy at La Plata National University (1887).

Although he spent three years in Europe, Ameghino remained isolated from the mainstream of scientific thought, which led him to misinterpret some of his fossil finds and to advance radical anthropological theories that drew severe criticism. He stated, in effect, that

all mammals, including humans, originated on the Argentine pampas. He was dismissed from his teaching posts, and so clouded was his reputation that only near the end of his life did other paleontologists begin to realize the value of his work. He was director of the Museum of Natural History, Buenos Aires (1902–11), and was reappointed professor of geology at La Plata National University in 1906. Nearly 200 monographs and memoirs are contained in *Obras completas y correspondencia científica de Florentino Ameghino*, 24 vol. (1913–36; "Complete Works and Scientific Correspondence of Florentino Ameghino").

Amelanchier, genus of flowering shrubs and small trees of the rose family (Rosaceae), several species of which have entered cultivation as ornamental plants. Most species are North American; exceptions include the shrubby *A. ovalis*, which ranges over Europe, and *A. asiatica*, a small tree of East Asia. A number of amelanchiers are variously called juneberry, sugarplum, serviceberry, or sarvistree. The name shadbush, or shadblow, refers to the tendency of certain species to produce their profuse small blossoms (before the leaves) when the shad swim upriver to spawn, in early spring in eastern North America. The terminal white flower clusters of the *Amelanchier* are followed by reddish to purple-black fruit resembling tiny apples. The fruits are eaten by birds. Some species bear fruit that is used in making jellies.

The popular ornamental species of *Amelanchier* include juneberry (*A. alnifolia*), a shrub that grows up to about 3 m (10 feet); shadblow serviceberry (*A. canadensis*), up to about 8 m; and Allegheny serviceberry (*A. laevis*), like *A. canadensis* but taller and with more nodding flower clusters. Downy serviceberry (*A. arborea*) is also similar to *A. canadensis* but is more vigorous and has larger hanging flower clusters. Apple serviceberry (*A. gran-*

Shadblow serviceberry (*Amelanchier canadensis*)
A to Z Botanical Collection

diflora), a natural hybrid of *A. arborea* and *A. laevis*, grows up to 9 m and has larger individual blossoms, pinkish on some trees. Running serviceberry (*A. stolonifera*) is a spreading shrub about 1 m tall, that is useful in semiwild plantings and for stabilizing soil, especially on embankments.

The wild types of *Amelanchier* appear to hybridize freely. Their differences are slight and often puzzling to both gardeners and horticulturists.

Amelung glass, American glass produced from 1784 to about 1795 by John Frederick Amelung, a native of Bremen in Germany. Financed by German and American promoters, Amelung founded the New Bremen Glassmanufactory near Frederick, Md., U.S., and

Covered tumbler of Amelung glass, New Bremen Glassmanufactory of John Frederick Amelung, New Bremen, Md., 1788; in the Corning Museum of Glass, Corning, N.Y.

attempted to establish a self-sufficient community, importing glassworkers and other craftsmen from Germany. The enterprise was encouraged by such men as George Washington, Thomas Jefferson, and Benjamin Franklin, and in 1789 a duty on window and other glass, the first protective tariff passed under the new U.S. Constitution, was proposed. Amelung's ambitious project failed to prosper, however, and in 1790 he petitioned Congress for help. After debating whether such a loan was within its constitutional powers and whether it was advisable to set such a precedent, Congress defeated the measure. The New Bremen industry subsequently failed.

Only a few authenticated pieces of Amelung glass survive, most of them presentation pieces decorated with restrained engraving.

Amen (Egyptian god): see Amon.

amen, expression of agreement, confirmation, or desire used in worship by Jews, Christians, and Muslims. The basic meaning of the Semitic root from which it is derived is "firm," "fixed," or "sure," and the related Hebrew verb also means "to be reliable" and "to be trusted." The Greek Old Testament usually translates amen as "so be it"; in the English Bible it has frequently been rendered as "verily," or "truly."

In its earliest use in the Bible, the amen occurred initially and referred back to the words of another speaker with whom there was agreement. It usually introduced an affirmative statement. For emphasis, as in solemn oaths, the amen was sometimes repeated. The use of the initial amen, single or double in form, to introduce solemn statements of Jesus in the Gospels (52 times in the Synoptic Gospels—Matthew, Mark, and Luke—and 25 times in the Gospel According to John) had no parallel in Jewish practice. Such amens expressed the certainty and truthfulness of the statement that followed.

Use of the amen in Jewish temple liturgy as a response by the people at the close of a doxology or other prayer uttered by a priest seems to have been common as early as the time of the 4th century BC. This Jewish liturgical use of amen was adopted by the Christians. Justin Martyr (2nd century AD) indicated that amen was used in the liturgy of the Eucharist and was later introduced into the baptismal service.

A final amen, added by a speaker who offered thanksgiving or prayers, public or private, to sum up and confirm what he himself had said, developed naturally from the earlier usage in which others responded with the amen. Use of the final amen is found in the Psalms and is common in the New Testament. Jews used amen to conclude prayers in ancient times, and Christians closed every prayer with it. As hymns became more popular, the use of the final amen was extended.

Although Muslims make little use of amen, it is stated after every recital of the first sura.

amendment, in government and law, an addition or alteration made to a constitution, statute, or legislative bill or resolution. Amendments can be made to existing constitutions and statutes and are also commonly made to bills in the course of their passage through a legislature. Since amendments to a national constitution can fundamentally change a country's political system or governing institutions, such amendments are usually submitted to an exactly prescribed procedure.

The best-known amendments are those that have been made to the U.S. Constitution; Article V makes provision for the amendment of that document. The first 10 amendments that were made to the Constitution are called the Bill of Rights. (See Rights, Bill of.) A total of 27 amendments have been made to the Constitution. For an amendment to be made, two-thirds of the members of each house of Congress must approve it, and three-fourths of the states must ratify it. Congress decides whether the ratification will be by state legislatures or by popularly elected conventions in the several states (though in only one instance, that of the Twenty-First Amendment, which repealed prohibition, was the convention system used). In many U.S. states, proposed amendments to a state constitution must be approved by the voters in a popular referendum.

Amenemhet, also spelled AMENEMHAT, name of kings of Egypt grouped below chronologically and indicated by the symbol ●.

● **Amenemhet I** (fl. 20th century BC), king of Egypt (reigned 1938–08 BC), founder of the 12th dynasty who, with a number of powerful nomarchs (provincial governors), restored unity to Egypt after the civil war that followed the death of his predecessor, under whom he had served as vizier.

Amenemhet, an experienced administrator, moved the capital from Thebes to a more central location at Itj-towy (near modern Al-Lisht), to the south of Memphis, and appointed his supporters to various posts within the administration. Levying troops from one of the nomarchies, Amenemhet sailed up the Nile River, destroying what resistance remained to his rule. To safeguard the Nile River delta, he built fortresses along the eastern and western frontiers. Amenemhet also added to the Temple of Amon at Thebes and built at various other sites in Upper Egypt.

In the 20th year of his reign, 1918 BC, Amenemhet made Sesostri I, his son, coregent. The younger ruler assumed the task of extending Egyptian control into Nubia to the south, advancing as far as the Second Cataract of the Nile and building fortifications at strategic points. Under Amenemhet, the copper mines in Sinai were worked and punitive raids were made against the local Bedouin tribes. In the 30th year of his father's reign, on returning from a raid against the Libyans in the Western Desert, Sesostri received news of Amenemhet's assassination and hastened back to the capital to assume the kingship.

The Instruction of Amenemhet, a political piece cast as an address of Amenemhet to Sesostri, described the assassination attempt and gave the new king advice concerning government. Another politically motivated work,

The Story of Sinuhe, described Sesostris' receipt of the news, his reaction, and the glory of his reign.

• **Amenemhet II** (fl. 19th century BC), king of Egypt (reigned 1876–42 BC), grandson of Amenemhet I (founder of the 12th dynasty). He furthered Egypt's trade relations and internal development.

While he was coregent with his father, Sesostris I, Amenemhet led a gold-mining expedition to Nubia. Later, during his own reign, more expeditions went to Nubia and Sinai for gold and copper, a new mine shaft was opened in Sinai, and a trade venture was made to Punt, on the African coast near modern Ethiopia. Statues of Amenemhet have been found at several Syrian cities; and treasure of his reign discovered in a temple at Tawd, a town in Upper Egypt, reveals Cretan and Syrian stylistic patterns, verifying foreign contacts. Within Egypt the provincial governors continued to play key administrative roles, and fine tombs were provided them near their hometowns. Amenemhet's pyramid tomb, built at Dahshūr, south of Memphis, was patterned after his father's, with a fine limestone casing built over mud-brick retaining walls and a rubble core. Near it was found the jewelry belonging to a daughter of Amenemhet, revealing the artistic heights of his reign.

• **Amenemhet III** (fl. 19th–18th century BC), king of Egypt (reigned 1818–1770 BC) of the 12th dynasty, who brought Middle Kingdom Egypt (comprising also the 11th and 13th dynasties) to a peak of economic prosperity by completing a system to regulate the inflow of water into Lake Moeris, in the Al-Fayyūm depression southwest of Cairo. The resulting stabilization of the water level also drained some of the marshes that had surrounded the old lake. As part of this great work, the labyrinth described by the Greek historian Herodotus was probably built nearby. It was probably a multifunctional building—palace, temple, town, and administrative centre; ruins of the structure exist south of Amenemhet's pyramid at Hawara, in Al-Fayyūm. To celebrate the reclamation of 153,600 acres (62,200 hectares) of land for agricultural use, Amenemhet erected two colossuses of himself nearby, later described by Herodotus.

Amenemhet also worked the turquoise mines at Sinai with unprecedented intensity. Permanent quarters were erected for the miners, with wells nearby and fortifications to repel Bedouin raiders. A temple to the goddess Hathor was also built. Quarries throughout Egypt and Nubia, to the south, likewise were the site of much activity to support the king's building enterprises. Except for minor punitive raids, his reign was peaceful.

In Nubia Amenemhet retained the empire won by his predecessors. Artifacts of his reign have been found from as far south as the Third Cataract of the Nile to as far northeast as Byblos, an important seaport in Lebanon, an indication of Egypt's primacy as a com-

mercial power. His was the last long and successful reign of the 12th dynasty.

Amenhotep, also called AMENOPHIS, name of Egyptian kings grouped below chronologically and indicated by the symbol ●.

• **Amenhotep I** (fl. 16th–15th century BC), king of Egypt (reigned 1514–1493 BC), son of Ahmose I, the founder of the 18th dynasty. He effectively extended Egypt's boundaries in Nubia (the modern Sudan).

The biographies of two soldiers confirm Amenhotep's wars in Nubia. As shown by a graffito from the seventh year of his reign, he reached the frontier at the Second Cataract of the Nile, probably establishing a frontier farther south on Sai Island. Amenhotep also raided Libya, but no details of the operation are recorded. His only confirmed activities in Asia are the reopening of the mines at Sinai and the reoccupation of the fortress erected there during the Middle Kingdom, but there is indirect evidence that he held territory in Syria.

Little is known about Amenhotep's building activity, because ancient Egyptian buildings were often demolished for stone. A fine, small limestone chapel of the king has been recovered, and the king's official in charge of construction credits another temple to Amenhotep. His tomb was probably a rock-cut structure separated from its temple, a departure from earlier royal practice. He founded the cemetery workers' village at Dayr al-Madinah in western Thebes, and in later periods both the king and his mother were worshiped there.

• **Amenhotep II** (fl. 15th century BC), king of Egypt (reigned c. 1426–1400 BC), son of Thutmose III. Ruling at the height of Egypt's imperial era, he strove to maintain his father's conquests by physical and military skills.

Amenhotep II offering sacrifices, statue, 15th century BC; in the Egyptian Museum, Cairo

By courtesy of the Egyptian Museum, photograph, Himer Fotoarchiv, München

Amenhotep II's upbringing was carefully guided by his warrior father, with great emphasis on physical strength, skills of warfare, and sportsmanship. Amenhotep never tired of boasting of his feats in these skills, and he was even buried with his great bow.

Amenhotep's first campaign was against uprisings in northern Syria, during which he extracted loyalty oaths from other Asiatic princes. Returning from Asia, he forwarded the body of a rebel Asiatic chief to the Nubian capital, where it was hung on the town wall as an example; the gesture was sufficient to maintain peace in Nubia. His second campaign was smaller, reaching only to the Sea of Galilee, but after it Amenhotep received gifts from Mitanni, Babylon, and the Hittites. No further northern war occurred, which suggests that a balance of power had been achieved.

Within Egypt, many of his father's administrators continued to serve Amenhotep, and

the king completed some buildings begun by Thutmose III. He also built new sanctuaries in Lower Egypt and added his mortuary temple in western Thebes. Amenhotep's mummy was discovered in the Valley of the Tombs of the Kings at Thebes, in his fine, well-preserved tomb.

• **Amenhotep III**, byname AMENHOTEP THE MAGNIFICENT (fl. 14th century BC), king of Egypt (reigned 1390–53 BC) in a period of peaceful prosperity, who devoted himself to expanding diplomatic contacts and to extensive building in Egypt and Nubia.

Amenhotep III, head of a statue from western Thebes, c. 1390 BC

Reproduced by courtesy of the trustees of the British Museum

In the fifth year of his reign Amenhotep conducted campaigns against a territory called Akuyata, far to the south of Egypt. Thereafter his reign was peaceful, except for some disturbances in the Nile River delta, which Amenhotep, son of Hapu, the king's most prominent official, quelled by carefully regulating access into Egypt by land and sea.

Amenhotep III in his early years enjoyed hunting in the tradition of his father, Thutmose IV, and grandfather, Amenhotep II, and on two occasions issued large commemorative scarabs to proclaim his feats. Early in his reign he married Tiy, who, though a commoner, was a shrewd and able woman. She became the chief queen and the mother of the reforming king Akhenaton. In the 11th year of his reign, Amenhotep ordered the excavation of a large artificial basin near her native city, Akhmim, 100 miles (160 km) north of Luxor.

Utilizing the talents of Amenhotep, son of Hapu, the king engaged in a great construction program, which included the mortuary temple in western Thebes, of which only the Colossi of Memnon survive, and a major temple in Nubia. The king also built the main portions of the temple of Luxor and a pylon in the temple of Karnak, both in ancient Thebes. He also constructed many buildings in Memphis.

Amenhotep carried on lively diplomatic exchanges with the other great contemporary powers, as confirmed by the Amarna Letters (diplomatic archive of Amenhotep III and Akhenaton), which reveal that Egyptian gold was exchanged for horses, copper, and lapis lazuli from Asia. He contracted political marriages with the sisters and daughters of the kings of Mitanni (a powerful empire on the Euphrates River in northern Syria) and Babylon, to consolidate alliances, and sought to marry a Hittite princess as well. Diplomatic correspondence was also sent to Assyria, Cyprus, and a number of Egypt's Syrian vassals. Late in Amenhotep's reign, Tushratta, the ruler of Mitanni, forwarded a divine image to Egypt, to cure the ailing king. Queen Tiy played a great role in his last days, and Tushratta even corresponded with her after her husband's death.

Amenemhet III, granite statue from Bubastis; in the British Museum

• **Amenhotep IV:** see Akhenaton.

Amenhotep, SON OF HAPU (b. c. 1440 BC, Athribis, Lower Egypt—d. c. 1360 BC), high official of the reign of Amenhotep III of Egypt, who was greatly honoured by the king within his lifetime and was deified more than 1,000 years later during the Ptolemaic era.

Amenhotep rose through the ranks of government service, becoming scribe of the recruits, a military officer, under Amenhotep III. While in the Nile River delta, Amenhotep was charged with positioning troops at checkpoints on the branches of the Nile to regulate entry into Egypt by sea; he also checked on the infiltration of Bedouin tribesmen by land. On one of his statues, he is called a general of the army.

Some time later, when he was placed in charge of all royal works, he probably supervised the construction of Amenhotep III's

Amenhotep, son of Hapu, black stone statue, c. 1360 BC; in the Egyptian Museum, Cairo

By courtesy of the Egyptian Museum, Cairo, photograph, Hirmer Fotoarchiv, München

mortuary temple at Thebes near modern Luxor, the building of another temple in Nubia (the modern Sudan), and the transport of building material and erection of other works. Two statues from Thebes indicate that he was also an intercessor in Amon's temple and that he supervised the celebration of one of Amenhotep III's Sed festivals (a renewal rite celebrated by the pharaoh after the first 30 years of his reign and periodically thereafter). The king honoured him by embellishing Athribis, his native city. Amenhotep III even ordered the building of a small funerary temple for him next to his own temple, a unique honour for a nonroyal person in Egypt.

Amenophis (Egyptian king): see Akhenaton.

Amenophis (kings of Egypt): see under Amenhotep.

amenorrhea, also spelled AMENORRHOEA, failure to menstruate. Menstruation is the normal cyclic bleeding from the uterus in the female reproductive tract that occurs at approximately four-week intervals. Primary amenorrhea is the delay or failure to start menstruating upon reaching the age of 16, while secondary amenorrhea is the abnormal cessation of cycles once they have started. Amenorrhea is not itself a disease. It reflects some failure in the intricate balance between the hypothalamus, the pituitary, the ovaries, and the uterus. The pituitary stimulates the ovaries by means of a hormone known as gonadotropin, which causes the ovaries to produce the reproductive hormones estrogen and progesterone. Estrogen, when released to the uterus (womb), regulates the menstrual (monthly reproductive) cycle and produces periods of bleeding if fertilization of the egg released from the ovary has not occurred. Any

disturbance in this chain of events can cause amenorrhea.

Hypothalamic amenorrhea is caused by emotional shock, anxiety, fear, or injuries to the midbrain. Amenorrhea may be the main or the only symptom in these disturbances.

Disorders that disrupt secretion by the pituitary include tumours, systemic diseases, and dietary deficiencies. When amenorrhea is primary, the reproductive organs remain infantile, the breasts do not develop, there is no pubic hair, there is dwarfism, and muscle development is deficient. When amenorrhea is secondarily caused by tumours, destructive lesions, or hemorrhagic shock, the genitals atrophy; pubic hair diminishes; there may be lethargy, weight loss, or obesity; and masculine traits may develop. Treatment is directed toward the underlying cause.

The ovarian disturbances causing amenorrhea include cysts, tumours, and excessive or deficient secretion of hormones. Most of the same genital symptoms occur as with the pituitary, but the growth pattern is different.

Other causes of amenorrhea include general obesity, obstructions of the vagina, and the normal bodily states of pregnancy, lactation, and menopause.

Amenouzume, in full AMENOZUME NO MIKOTO, in Japanese mythology, the celestial goddess who performed a spontaneous dance enticing the sun goddess Amaterasu out of the cave in which she had secluded herself and had thus deprived the world of light.

Amenouzume decorated herself with club moss and leaves of the *sakaki* tree, lit bonfires, and made a platform of an upturned tub. Her inspired cries and divine dancing, in the course of which she exposed herself, so delighted the assembled gods that they roared in laughter, thus awakening the curiosity of the sun goddess.

Amenouzume is the patron goddess of dancers. The classical music and dancing used in Shintō religious ceremonies, *kagura*, is said to have originated with her performance. In popular mythology, as the embodiment of the female principle, she is often associated with Sarudahiko (*q.v.*), who represents male sexuality and who offered himself as a guide to the divine grandchild Ninigi when he descended to earth. Amenouzume and Sarudahiko are sometimes pictured as husband and wife.

amensalism, association between organisms of two different species in which one is inhibited or destroyed and the other is unaffected. There are two basic modes: competition (*q.v.*), in which a larger or stronger organism excludes a smaller or weaker one from living space or deprives it of food, and antibiosis, in which one organism is unaffected but the other is damaged or killed by a chemical secretion.

The classic demonstration of antibiosis is the destructive effect that the bread mold *Penicillium* has upon certain bacteria; the secretion, known as penicillin, has become a potent medicine in combating bacterial infections. Some higher plants secrete substances that inhibit the growth of—or kill outright—nearby competing plants. An example is the black walnut (*Juglans nigra*), which secretes juglone, a substance that destroys many herbaceous plants within its root zone. The composition of chaparral and desert in the western United States is largely dependent on such antibiotic associations between species, which results in stable communities that have been freed of competition for scarce water.

Āmer, also called AMBER, town, east-central Rājasthān state, northwestern India. Āmer is part of the Jaipur urban agglomeration and is noted for its magnificent palace. The town is entirely surrounded by hills and stands at the foot of a rocky gorge. Āmer was made the capital of the state of the Kachwāhā Rājputs

(warrior rulers of the historical region of Rājputāna) in the 12th century and for 600 years continued to be a political centre. The palace, an example of Rājput architecture, was begun about 1600 and was the royal residence until the capital was transferred to Jaipur in 1728. The palace's Mughal-influenced architecture includes the maharaja's apartments, a hypostyle hall, and several temples, all grouped around an imposing courtyard. Jaigarh fort stands on a hill summit overlooking the town. Pop. (1991) 23,289.

America (Western Hemisphere): see Americas.

America, Volunteers of: see Volunteers of America.

America First Committee, influential political pressure group in the United States (1940–41) that opposed aid to the Allies in World War II because it feared direct American military involvement in the conflict. The committee claimed a membership of 800,000 and attracted such leaders as General Robert E. Wood, the aviator Charles A. Lindbergh, and Senator Gerald P. Nye. Though failing in its campaigns to block the Lend-Lease Act, the use of the U.S. Navy for convoys, and the repeal of the Neutrality Act, its public pressure undoubtedly discouraged greater direct military aid to a Great Britain beleaguered by Nazi Germany. After the Japanese attack on Pearl Harbor (Dec. 7, 1941), the committee dissolved and urged its members to support the war effort.

American Academy of Arts and Sciences, honorary society incorporated on May 4, 1780, in Boston, Mass., U.S., for the purpose of cultivating "every art and science." Its membership—some 3,300 fellows in the United States and about 550 foreign honorary fellows (all scholars and national leaders)—is divided into four classes: the physical sciences, the biological sciences, the social arts and sciences, and the humanities and fine arts. Offices are in Cambridge, Mass.

The society was established in 1779 by a group of Harvard College graduates—including John Adams, Samuel Adams, John Hancock, and James Bowdoin—and incorporated in 1780. It evolved largely as a rival to the earlier American Philosophical Society established in Philadelphia in 1743 but ultimately became the larger society, claiming to represent the United States nationally. Its publications include the *Bulletin* (eight times a year) and *Daedalus* (quarterly). The academy holds a convention each May in Cambridge, conducts various other conferences and seminars, and presents the Emerson-Thoreau Medal, the Amory Prize, the Rumford Premium, the Sarton Fellowship, the Scholar Patriot Award, the Talcott Parsons Prize, and the American Academy Award for Humanistic Studies.

American Airlines, Inc., major American airline serving cities in several states of the continental United States and in Canada, Hawaii, Mexico, Central and South America, the Caribbean, Europe, and the western Pacific. Its parent, or holding, company, AMR Corp. (created in 1982), also has holdings in food-catering services, hotels and inns, airport ground-transportation and baggage-handling services, airport maintenance services, and other related businesses. Corporate headquarters are in Dallas, Texas.

American Airlines developed over the years out of the union or merger of some 85 companies. Two nucleate companies were Robertson Aircraft Corporation and Colonial Air Transport. Robertson Aircraft, first organized in 1921 in Missouri as a general flying service and manufacturer, flew its first mail route on April 15, 1926, between Chicago and St. Louis, Mo.; the pilot on the first flight was Charles

A. Lindbergh. Colonial Air, which developed out of a charter service called The Bee Line formed in 1923, flew mail between New York City and Boston, beginning June 18, 1926. In 1929 these airlines were combined under a holding company, The Aviation Corporation, which was reorganized as an operating company and renamed American Airways, Inc., in 1930. In that year, in the amalgamation of several airlines, the company had routes extending from Boston and New York City to San Diego and Los Angeles, via Cleveland and Kansas City. In 1934, when most American airlines were compelled to reorganize owing to new congressional guidelines and the loss of mail contracts, the company thoroughly reworked its routes into an integrated system and was renamed and reincorporated as American Airlines, Inc. Cyrus Rowlett Smith was elected president in that year and, as president or chairman of the board, guided the company's fortunes until 1968, when he became U.S. secretary of commerce. Returning briefly as chief executive officer in 1973, he retired in 1974.

The airline expanded greatly from the 1970s to the '90s, developing from a basically domestic American airline into an international carrier reaching the Caribbean, South America, Europe, and the Pacific, largely by buying routes of other airlines. In 2001 it acquired the American carrier Trans World Airlines.

American Anti-Slavery Society (1833-70), promoter, with its state and local auxiliaries, of the cause of immediate abolition of slavery in the United States.

As the main activist arm of the Abolition movement (see abolitionism), the society was founded in 1833 under the leadership of William Lloyd Garrison. By 1840 its auxiliary societies numbered 2,000, with a total membership ranging from 150,000 to 200,000. The societies sponsored meetings, adopted resolutions, signed antislavery petitions to be sent to Congress, published journals and enlisted subscriptions, printed and distributed propaganda in vast quantities, and sent out agents and lecturers (70 in 1836 alone) to carry the antislavery message to Northern audiences.

Participants in the societies were drawn mainly from religious circles (e.g., Theodore Dwight Weld) and philanthropic backgrounds (e.g., businessmen Arthur and Lewis Tappan and lawyer Wendell Phillips), as well as from the free black community, with six blacks serving on the first Board of Managers. The society's public meetings were most effective when featuring the eloquent testimony of former slaves such as Frederick Douglass or William Wells Brown. The society's antislavery activities frequently met with violent public opposition, with mobs invading meetings, attacking speakers, and burning presses.

In 1839 the national organization split over basic differences of approach: Garrison and his followers were more radical than other members; they denounced the U.S. Constitution as supportive of slavery and insisted on sharing organizational responsibility with women. The less radical wing, led by the Tappan brothers, formed the American and Foreign Anti-Slavery Society, which advocated moral suasion and political action and led directly to the birth of the Liberty Party (q.v.) in 1840. Because of this cleavage in national leadership, the bulk of the activity in the 1840s and '50s was carried on by state and local societies. The antislavery issue entered the mainstream of American politics through the Free-Soil Party (1848-54) and subsequently the Republican Party (founded in 1854). The American Anti-Slavery Society was formally dissolved in 1870, after the Civil War and Emancipation.

American arborvitae, also called EASTERN ARBORVITAE, or NORTHERN WHITE CEDAR (*Thuja occidentalis*), ornamental and timber evergreen conifer of the cypress family (Cupressaceae), native to eastern North America.

In the lumber trade it is called, among other names, white cedar, eastern white cedar, and New Brunswick cedar.

Often 20 m (65 feet) tall, the tree is the most common and probably the hardiest of the arborvitae. Its trunk is sometimes forked near the ground into several main stems covered

American arborvitae (*Thuja occidentalis*)

G.J. Chalans

with reddish brown bark. The cones have 8 to 10 scales, of which only four are usually fertile. Most cultivated varieties are narrow, densely pyramidal shrubs, and many have interesting variations in foliage colour.

American Association for the Advancement of Science (AAAS), the largest general scientific society in the United States. It was founded in 1847 in Boston, Mass., by a number of geologists and naturalists and held its first meeting in Philadelphia, Pa., in 1848. Its goals are to further the work of scientists, to facilitate cooperation among them, to improve the effectiveness of science in the promotion of human welfare, and to increase public understanding and appreciation of the role of science in human progress. By the late 20th century the AAAS had more than 130,000 individual members. The organization represents all the major branches of science and is divided into sections representing most of them. The AAAS conducts conferences and meetings in coordination with its formal affiliates, which include nearly 300 scientific societies, professional organizations, and state and city scientific academies.

The headquarters of the AAAS are in Washington, D.C. Its major publications are the weekly journal *Science*; *Science Education News*, published six times a year; *Science Books & Films*, which appears six times a year; and a series of symposium volumes.

American Association of Retired Persons (AARP), nonprofit, nonpartisan organization that works to address the needs and interests of middle-aged and elderly people in the United States. Its membership is open to all persons age 50 or older, whether working or retired. It is headquartered in Washington, D.C.

The AARP was founded in 1958 by a retired teacher, Ethel Percy Andrus, with the goal of helping older Americans remain physically and intellectually active by serving others. In 1982 the AARP merged with the National Retired Teachers Association (NRTA), an organization that Andrus had founded in 1947 to obtain pension and health insurance benefits for retired educators.

The AARP offers a broad range of services and benefits to its members. Among these are a group health insurance program; special discounts on automobile rental, airline, and hotel rates; automotive insurance; a credit union; and pharmacy and travel services. It sponsors community-service programs in such areas as crime prevention, defensive driving, adult education, consumer affairs, and the counseling of widowed persons. A program on retirement planning is also offered, and special services to retired teachers are provided through the NRTA. The AARP issues video programs and

printed materials on various health topics and on other aging-related issues. Its publications include a bimonthly magazine, *Modern Maturity*, and the monthly *AARP Bulletin*. Volunteers implement most of the community service and other programs through the local chapters of the AARP. The AARP's board of directors serve on a voluntary basis and are elected at a biennial convention.

One of the AARP's major functions is as a legislative advocate for the elderly at the federal and state levels, working to influence the passage of legislation that affects older citizens. The steadily rising proportion of elderly in the American population had given the AARP a membership of more than 30 million by the beginning of the 21st century. This large membership, coupled with the higher voting rates of elderly Americans, helped make the AARP one of the most powerful advocacy groups in American politics.

American Ballet, company founded in conjunction with the School of American Ballet in 1934 by Lincoln Kirstein and Edward Warburg, with George Balanchine as artistic director. Its initial performances were held in 1934 in Hartford, Conn., U.S. In 1935 it became the resident ballet company for the Metropolitan Opera in New York City, whose disapproval of Balanchine's unconventional choreography caused the ballet company to disband temporarily in 1938.

Ballet Caravan, founded by Kirstein in 1936 to produce works by young American choreographers, presented many American Ballet dancers in the early works of Eugene Loring, Lew Christensen, and William Dollar. The company toured the United States in 1938. Its dancers rejoined the American Ballet, renamed the American Ballet Caravan, in 1941 for a government-sponsored tour of South America. After the tour the companies disbanded, but they formed the nucleus for the founding of the New York City Ballet (q.v.) in 1946 (then called Ballet Society). The School of American Ballet continued to be a creative centre of American ballet as a part of the latter company.

American Ballet Theatre, formerly (1939-57) BALLET THEATRE, ballet company based in New York City and having an affiliated school. It was founded in 1939 by Lucia Chase and Richard Pleasant and presented its first performance on Jan. 11, 1940. Chase was director, with Oliver Smith, from 1945 to 1980; the dancer Mikhail Baryshnikov was artistic director from 1980 to 1989; dancer Kevin McKenzie assumed that role in 1992.

Works were created for the company by such choreographers as Antony Tudor, Agnes de Mille, Jerome Robbins, Michael Kidd, Eliot Feld, Twyla Tharp, Glen Tetley, and Mikhail Baryshnikov; Michel Fokine revived many of his masterpieces for the company and created *Bluebeard* (1941) and *Russian Soldier* (1942). Such dancers as Alicia Alonso, Baryshnikov, Erik Bruhn, Anton Dolin, André Eglevsky, Cynthia Gregory, Rosella Hightower, Nora Kaye, John Kriza, Hugh Laing, Natalia Makarova, Alicia Markova, Ivan Nagy, Janet Reed, Violette Verdy, and Igor Youskevitch were members of the company.

American Baptist Association, fellowship of autonomous Baptist churches, organized in 1905 by Baptists who withdrew from the Southern Baptist Convention. Originally known as the Baptist General Association, the fellowship adopted its present name in 1924. It was a development of the Landmarkist (or Landmarkist) teaching of some Southern Baptists in the mid-19th century. They believed that early Christians were Baptists who baptized only adult believers by immersion and

who were organized in local autonomous congregations. The Landmarkers wished to retain what they considered the "old landmarks" of early Christianity, and, therefore, they refused to cooperate or associate with non-Baptist churches and other Baptists with whom they disagreed. As the Southern Baptist Convention adopted a more centralized denominational church government, the Landmarkers believed the local church was losing its autonomy, and eventually they withdrew to form their own fellowship.

American Baptist Churches in the U.S.A., association of Baptist churches organized in 1907 as the Northern Baptist Convention, which became the American Baptist Convention in 1950 and took its present name in 1973. It grew out of Baptist associations and societies organized by Baptist churches in the United States in the 18th and 19th centuries.

Through the missionary activity of the Philadelphia Baptist Association, which was organized in 1707 by five Baptist churches in Pennsylvania, Delaware, and New Jersey, many other Baptist churches were organized. More associations of local churches were formed, and by 1800 about 48 such associations existed in the United States. In the 19th century the Baptists began cooperating in national organizations formed for specific purposes, mainly overseas missionary work. In 1824 the American Baptist Publication Society was organized and in 1832, the American Baptist Home Mission Society (since 1973 called the Board of National Ministries).

Disagreements between Southern and Northern Baptists over slavery led the Southern Baptists to form an independent organization in 1845, the Southern Baptist Convention. The mission and publication societies continued to operate independently in the North and West until they became part of the Northern Baptist Convention in 1907.

Generally considered more liberal than the Southern Baptist Convention, the American Baptist Churches in the U.S.A. is a member of the National Council of Churches of Christ in the U.S.A. and of the World Council of Churches. It has taken an active part in ecumenical affairs and has worked for closer union among the various Baptist groups.

The denomination meets annually and carries out its work through various divisions and societies. The basic units are the autonomous local churches, which are grouped into state conventions. Headquarters are in Valley Forge, Pa.

American Bar Association (ABA), voluntary association of American lawyers and judges. The ABA was founded in 1878, and by the late 20th century it had about 375,000 members. Its headquarters are in Chicago, Ill.

Nongovernmental in nature, the ABA seeks to encourage improvements in the legal profession, to ensure the availability of legal services to all citizens, and to improve the administration of justice. It conducts educational and research projects toward these ends. The ABA's work is principally carried out by a number of sections and standing and special committees, each of which is devoted to a special field of practice or to subjects of special concern to the bar and the public. The various sections and committees debate and research legal and professional questions and then submit the resolutions they have adopted to the ABA's governing bodies, the House of Delegates and the Board of Governors, which then act upon them. The ABA publishes the *American Bar Association Journal* monthly.

American Basketball Association (ABA), former professional basketball league formed in the United States in 1967 to rival the

older National Basketball Association (NBA). George Mikan, a former star player in the NBA, was the ABA's first commissioner. The ABA fielded 11 teams in its first season.

At a proposed merger between the ABA and the NBA, a class action was instituted by ABA players alleging violations of the antitrust laws. The settlement in 1976 resulted in the dissolution of the ABA, with four ABA teams absorbed into the NBA, a dispersal draft of certain ABA players by NBA teams, and the remaining players granted permission to act as free agents.

American bear: see black bear.

American Bible Society (ABS), international agency under lay control, formed in New York in 1816 as a union of 28 local Bible societies "to encourage the wider circulation of the Holy Scriptures throughout the world, without note or comment, through translation, publication, distribution, and stimulation of use." Early in its history it set as its goal the placing of a Bible in every home, including those on the frontier. The ABS is supported by more than 80 Protestant denominations.

American Brands, Inc., American industrial conglomerate that was once the world's largest cigarette maker. It was formed in 1969 as the parent company for the American Tobacco Company (founded 1890). Corporate headquarters are in Old Greenwich, Conn.

The history of the American Tobacco Company traces to the post-Civil War period in North Carolina, when a Confederate veteran, Washington Duke, began trading in tobacco. In 1874 he and his sons, Benjamin N. Duke and James Buchanan Duke, built a factory and in 1878 formed the firm of W. Duke, Sons & Co., one of the first tobacco companies to introduce cigarette-manufacturing machines.

Entering the "cigarette war," the Dukes eventually established the American Tobacco Company in 1890, with James as president. Through mergers and purchases, the Duke brothers eventually acquired corporate control of virtually the entire American tobacco industry—some 150 factories in all. In 1911, however, after five years of litigation, a U.S. Court of Appeals judged this tobacco trust in violation of the Sherman Anti-Trust Act and ordered it dissolved. The main manufacturers to emerge, in addition to American, were R.J. Reynolds, Liggett & Myers, and Lorillard.

In 1916 American introduced its most popular cigarette brand, Lucky Strike, and in 1939 it introduced one of the first king-size cigarettes, Pall Mall (an old name reapplied to a new cigarette). The sales of these two brands made American Tobacco the most successful cigarette manufacturer in the 1940s. The company failed to establish equally strong brands of filter cigarettes in the 1950s, however, and by the 1970s it had slipped to a minor position among U.S. tobacco makers.

American Tobacco began diversifying in the 1960s with the purchase of Gallaher Ltd., one of the largest tobacco companies in Great Britain. It acquired the Franklin Life Insurance Company in 1979, and its other subsidiaries make Jim Beam whiskey, Master locks, and Acco office supplies. In 1994 American Brands sold its tobacco unit, American Tobacco Company, to the British conglomerate B.A.T. Industries PLC.

American Broadcasting Company (ABC), major American television network that is a division of the Walt Disney Company. Its headquarters are in New York City.

The company's history traces to 1926, when the Radio Corporation of America (RCA) and several other firms founded the National Broadcasting Company (NBC) to operate a nationwide radio broadcasting network. NBC expanded so rapidly that by 1928 it found itself with an excess of affiliates in the same cities, so it split its programming into two

separate networks called the Red and the Blue networks. After the Federal Communications Commission declared in 1941 that no company could own more than one radio network, NBC sold the Blue Network to Edward J. Noble, the millionaire maker of Life Savers candy, who named it the American Broadcasting System. The following year he changed the company's name to American Broadcasting Company, Inc. (ABC).

In 1953 United Paramount Theatres, the movie theatre arm of Paramount Pictures, merged with ABC, which thereby became the owner of several hundred American movie houses (many of which were sold in 1974). The merger provided ABC with the capital it needed to expand its presence in the new medium of television, and it quickly became one of the three major television networks. From the early 1960s the ABC television network was a major broadcaster of sports; instant replay was developed by ABC engineers in 1961. In 1955 ABC entered the phonograph record business with the purchase of a subsidiary and, over the years, under the consolidated ABC Records Division, developed such labels as ABC, Westminster, Dot, and Impulse. In 1979 the record division was sold and a video division was begun. In 1985 ABC Companies was purchased by Capital Cities Communications, Inc. In 1995-96 Capital Cities/ABC Inc. was acquired by the Walt Disney Company for \$19,000,000,000, thereby creating the world's largest media and entertainment company.

American Can Company: see Travelers Inc.

American Civil Liberties Union (ACLU), organization founded by Roger Baldwin and others in New York City in 1920 to champion constitutional liberties in the United States. The ACLU works to protect Americans' constitutional rights and freedoms as set forth in the U.S. Constitution and its amendments. The ACLU works in three basic areas: freedom of expression, conscience, and association; due process of law; and equality under the law.

The ACLU seeks to further particular aspects of civil liberties by affecting the outcome of specific legal cases in the courts. From its founding the ACLU has initiated test cases as well as intervened in cases already in the courts. Thus it may directly provide legal counsel in a case, or it may comment on the civil-liberties issues in a case by filing a "friend of the court" (*amicus curiae*) brief.

One of the ACLU's most famous test cases was the *Scopes* trial (1925), in which it supported the decision of a Tennessee science teacher, John T. Scopes, to defy a Tennessee law forbidding the teaching of Charles Darwin's theory of evolution. It has been active in overturning censorship laws, often through test cases resulting from the deliberate purchase of banned material and consequent arrest and trial. The ACLU has not always succeeded in these trials, but the public airing of the issues has often led to success on appeal or in legislative reconsideration later. As a result of its efforts against censorship, such books as James Joyce's *Ulysses*, among others, could be imported into the United States. The ACLU provided defense counsel in the *Sacco-Vanzetti* case in 1921 and the *Scottsboro* case of 1931-35. One of the ACLU's most significant freedom-of-religion cases involved the defense in the late 1930s of Jehovah's Witnesses who refused, on the grounds of conscience, to allow their children to salute the flag in their public classrooms.

In the 1950s and '60s the ACLU handled cases questioning the constitutionality of loyalty oaths and the blacklisting of supposed left-wing "subversives." It also played a role in Supreme Court decisions banning prayer in public schools as a violation of the constitutional principle of the separation of church

and state. In the 1960s the ACLU participated in cases that established the right of indigent defendants to legal counsel in criminal prosecutions, and in the same period it was involved in decisions barring the use in court of evidence that was obtained through illegal searches or seizures by the police.

The work of the ACLU is performed by thousands of volunteers and about 300 full-time staff members, including many lawyers, who provide legal counsel free of charge. The ACLU is headed by a national board of directors and is headquartered in New York City. In the late 20th century the ACLU had about 275,000 members.

American Civil War, also called **WAR BETWEEN THE STATES**, in U.S. history, a four-year war (1861–65) between the federal government of the United States and 11 Southern states that asserted their right to secede from the Union.

A brief treatment of the American Civil War follows. For full treatment, see *MACROPAEDIA: United States of America*.

The secession of the Southern states (in chronological order, South Carolina, Mississippi, Florida, Alabama, Georgia, Louisiana, Texas, Virginia, Arkansas, Tennessee, and North Carolina) in 1860–61 and the ensuing outbreak of armed hostilities were the culmination of decades of growing sectional friction over the related issues of slavery, trade and tariffs, and the doctrine of states' rights. This friction arose out of fundamental differences between the economies of the Northern and Southern states. The North had a growing manufacturing sector and small farms using free labour, while the South's economy was based on large farms (plantations) using slave labour. In the 1840s and '50s the Northern states wanted to prohibit slavery in the Western territories that would eventually become new states. The Southern states opposed all efforts to block the expansion of slavery and feared that the North's stance would eventually endanger existing slaveholdings in the South itself. By the 1850s, some Northerners had begun calling for the complete abolition of slavery, while several Southern states threatened to secede from the Union as a means to protect their right to keep slaves. When Abraham Lincoln, the candidate of the antislavery Republican Party, was elected president in late 1860, the Southern states seceded.

Organized as the Confederate States of America, the Southern states, under President Jefferson Davis, counted on patriotic fervour, the strategic advantage of interior lines of communication, and the international importance of their chief cash crop, cotton, to win a short war of independence. The Northern states of the federal Union, under President Abraham Lincoln, commanded more than twice the population of the Confederacy and held even greater advantages in manufacturing and transportation capacity.

War began in Charleston, S.C., with the firing of Confederate artillery on Fort Sumter on April 12, 1861. Both sides quickly began raising and organizing armies. On July 21 some 30,000 Union troops marching toward the Confederate capital of Richmond, Va., were stopped at Bull Run (Manassas) and then driven back to Washington, D.C., by Confederates under General Thomas J. "Stonewall" Jackson and General P.G.T. Beauregard. The shock of defeat galvanized the Union, which called for 500,000 more recruits. General George B. McClellan was given the job of training the Union's Army of the Potomac.

The first major campaign of the war began in February 1862, when the Union general Ulysses S. Grant captured the Confederate strongholds of Fort Henry and Fort Donelson in western Tennessee; this action was followed by the Union general John Pope's capture of

New Madrid, Mo., a bloody but inconclusive battle at Shiloh (Pittsburg Landing), Tenn., on April 6–7, and the occupation of Corinth and Memphis, Tenn., in June. Also in April, the Union naval commodore David G. Farragut gained control of New Orleans. In the East, McClellan launched a long-awaited offensive with 100,000 men in another attempt to capture Richmond. Opposed by General Robert E. Lee and his able lieutenants Jackson and J.E. Johnston, McClellan moved cautiously and in the Seven Days' Battles (June 25–July 1) was turned back, his Peninsular Campaign a failure. At the Second Battle of Bull Run (August 29–30), Lee drove another Union army, under Pope, out of Virginia and then invaded Maryland. McClellan checked Lee's forces at Antietam (or Sharpsburg, September 17). Lee withdrew, regrouped, and dealt McClellan's successor, A.E. Burnside, a heavy defeat at Fredericksburg, Va., on December 13.

Burnside was in turn replaced as commander of the Army of the Potomac by General Joseph Hooker, who took the offensive in April 1863. He attempted to outflank Lee's position at Chancellorsville, Va., but was completely outmaneuvered (May 1–5) and forced to retreat. Lee then undertook a second invasion of the North. He entered Pennsylvania, and a chance encounter of small units developed into a climactic battle at Gettysburg (July 1–3), where the new Union commander, General George G. Meade, commanded defensive positions. Lee's forces were repulsed at the Battle of Gettysburg and fell back into Virginia. At almost precisely the same time, a turning point was reached in the West. After two months of masterly maneuvering, Grant captured Vicksburg, Miss., on July 4, 1863, and soon the Mississippi River was entirely under Union control. In October, after a Union army under General W.S. Rosecrans had been defeated at Chickamauga Creek, Ga. (September 19–20), Grant was called to take command in that theatre. Aply assisted by General William T. Sherman and General George Thomas, Grant drove Confederate general Braxton Bragg out of Chattanooga (November 23–25) and out of Tennessee; Sherman subsequently secured Knoxville.

In March 1864 Lincoln gave Grant supreme command of the Union armies. Grant took personal command of the Army of the Potomac in the east and soon formulated a strategy of attrition based upon the Union's overwhelming superiority in numbers and supplies. He began to move in May, suffering extremely heavy casualties in the battles of the Wilderness, Spotsylvania, and Cold Harbor, all in Virginia, and by mid-June he had Lee pinned down in fortifications before Petersburg, Va. For nearly 10 months the siege of Petersburg continued, while Grant slowly closed around Lee's positions. Meanwhile, Sherman faced the only other Confederate force of consequence in Georgia. Sherman captured Atlanta early in September, and in November he set out on his 300-mile (480-kilometre) march through Georgia, leaving a swath of devastation behind him. He reached Savannah on December 10 and soon captured it.

By March 1865 Lee's army was thinned by casualties and desertions and was desperately short of supplies. Grant began his final advance on April 1 at Five Forks, captured Richmond on April 3, and accepted Lee's surrender at nearby Appomattox Court House on April 9. Sherman had moved north into North Carolina, and on April 26 he received the surrender of J.E. Johnston. The war was over.

Naval operations in the Civil War were secondary to the war on land, but there were nonetheless some celebrated exploits. David Farragut was justly hailed for his actions at New Orleans and at Mobile Bay (Aug. 5, 1864), and the battle of the ironclads *Monitor* and *Merrimack* (March 9, 1862) is often held

to have opened the modern era of naval warfare. For the most part, however, the naval war was one of blockade as the Union attempted, largely successfully, to stop the Confederacy's commerce with Europe.

The North's victory in the American Civil War resulted in the preservation of the Union, the abolition of slavery, and the granting of citizenship to the freed slaves. The war also marked the new economic and political ascendancy of the rapidly industrializing, increasingly urbanized states of the North.

American Colonization Society, organization founded in the United States in 1817 to transport free-born blacks and emancipated slaves to Africa.

The society's program focused on purchasing and freeing slaves, paying their passage to the west coast of Africa, and assisting them after their arrival there. In 1821, after protracted negotiations with local chiefs, the society acquired the Cape Mesurado area, subsequently the site of Monrovia, Liberia. The society was opposed by many antislavery advocates because it drained off the best of the free black population while still preserving slavery. Reviled by extremists on both sides of the slavery dispute and suffering from a shortage of money, the society declined after 1840. In 1847 Liberia, until then virtually an overseas branch of the society, declared its independence. Between 1821 and 1867 about 6,000 blacks were resettled by the group, which was dissolved in 1912.

American Dictionary of the English Language, **An** (1828), two-volume dictionary by the American lexicographer Noah Webster. He began work on it in 1807 and completed it in France and England in 1824–25, producing a two-volume lexicon containing 12,000 words and 30,000 to 40,000 definitions that had not appeared in any earlier dictionary. Because it was based on the principle that word usage should evolve from the spoken language, the work was attacked for its "Americanism," or unconventional preferences in spelling and usage, as well as for its inclusion of nonliterary words, especially technical terms in the arts and sciences. Despite harsh criticism, the work sold out, 2,500 copies in the United States and 3,000 in England, in little over a year. It was relatively unpopular thereafter, however, despite the appearance of the second, corrected edition in 1840; and the rights were sold in 1843 by the Webster estate to George and Charles Merriam.

American Equal Rights Association (AERA), organization that, from 1866 to 1869, worked to "secure Equal Rights to all American citizens, especially the right of suffrage, irrespective of race, color, or sex."

The AERA was founded in 1866 by Elizabeth Cady Stanton and Susan B. Anthony. It split a short time later over the issue of race, when Stanton and Anthony alienated the Abolitionists by insisting that the suffrage focus be on women rather than blacks. In 1869 Stanton and Anthony formed the exclusively female National Woman Suffrage Association. Lucy Stone, Julia Ward Howe, and other conservative feminists formed the American Woman Suffrage Association, and the AERA was dissolved.

American Evangelical Lutheran Church, church established by Danish immigrants who in 1874 took the name Danish Evangelical Lutheran Church in America and formally organized as a synod in Neenah, Wis., in 1878. A constitution was accepted in 1879, and the present name was adopted in 1954. In 1962 the American Evangelical Lutheran Church (with about 24,000 members), the

United Lutheran Church in America, the Augustana Evangelical Lutheran Church, and the Suomi Synod merged into the Lutheran Church in America.

American Express Company, U.S. company founded on March 18, 1850, as an express-transportation company, but today operating as a worldwide organization providing primarily travel-related and insurance services and international finance operations and banking. Headquarters are in New York City.

The original company resulted from the consolidation of three companies active in the express transport of goods, valuables, and specie between New York City and Buffalo and points in the Midwest: (1) Livingston, Fargo & Company (formerly Western Express), founded in 1845 by Henry Wells (1805-78) and William G. Fargo (1818-81), later of Wells Fargo fame; (2) Wells & Co. (formerly Livingston, Wells & Co.), cofounded by Wells in 1846 and under his ownership at the time of the merger; and (3) Butterfield & Wasson, founded by John Butterfield (1801-69) and James D. Wasson. American Express was at first an unincorporated association of investors headed by Wells as president and Fargo as secretary. By the end of the American Civil War, its business had so flourished, with some 900 offices in 10 states, that it attracted competition in 1866 in the formation of Merchants Union Express Company. For two years the two companies engaged in cutthroat competition and, on the verge of financial exhaustion, finally merged on Nov. 25, 1868, to form the American Merchants Union Express Company, with Fargo succeeding as president. The company was renamed American Express Company in 1873.

On Fargo's death in 1881, his younger brother, James Congdell Fargo (1829-1915), became president and ruled for 33 years, introducing the American Express Money Order (1882) and the American Express Travelers Cheque (1891) and opening the first European office in Paris (1895), where various touring and banking activities were soon handled along with the company's traditional freight business. The first separate Travel Department was established in 1915 in New York City.

On July 1, 1918, the U.S. federal government nationalized the express industry, consolidating all domestic express operations in the American Railway Express Company (reorganized and denationalized in 1929). Deprived of its express business, American Express turned almost wholly to its travel and banking operations (though it continued its international freight business until its sale in 1970).

American Express Company (newly incorporated in 1965) now operates primarily in four areas: travel, insurance, banking, and investment services. In travel, it provides travelers checks, credit cards (American Express and Optima), travel agencies, tour packages, and agencies for motel and car-rental reservations. In insurance, it has owned since 1968 the Fireman's Fund American Insurance Companies group, which offers a wide range of insurance policies for individuals or groups. In banking, its American Express International Banking Corp. and subsidiaries conduct commercial banking in Europe, the Middle East, Asia, and elsewhere. In investment services, the company built a large network of operations through acquisitions made in the 1980s, which resulted in the subsidiary Shearson Lehman/ Brothers, one of the largest investment services firms in the United States, with operations in securities underwriting, and distribution, investment management, options and commodities brokerage, real-estate financing, corporate

finance, and money-markets trading. American Express also has diversified holdings in such areas as education, publishing, research, geophysical exploration, and cable television. In 1984 American Express acquired Investors Diversified Services Inc., a large Minneapolis-based insurance, mutual fund, and financial advisory concern.

American Farm Bureau Federation, largest farmers' organization in the United States, a federation of 49 state farm bureaus and the Puerto Rico farm bureau. It was founded in 1919.

The federation was an outgrowth of the county farm bureau movement. Shortly before World War I, the idea of using county demonstration agents, agricultural experts, or extension workers to provide farmers with the results of scientific study was adopted in a number of areas. In many localities these agents were supported by local groups of farmers who constituted county committees or bureaus. Before the end of the war the county farm bureaus in several states had formed state organizations. In November 1919 representatives of the state farm bureaus met in Chicago and organized the American Farm Bureau Federation.

The federation quickly became active in sponsoring a wide variety of political measures. In the 1930s it took a major part in formulating and obtaining passage of the Agricultural Adjustment Acts of 1933 and 1938. During World War II it opposed price controls. Later, it advocated measures to reduce government farm price supports and return the direction of the farm economy more largely to commercial markets. In general, the federation tended to favour agribusiness, while still maintaining the allegiance of many small farmers.

In the late 20th century membership (mostly on the basis of families) exceeded 3,000,000. The federation holds annual conventions and publishes *Farm Bureau News* (weekly).

American Federation of Labor-Congress of Industrial Organizations (AFL-CIO), American federation of autonomous labour unions formed in 1955 by the merger of the AFL (founded 1886), which was originally based on the principle of organizing workers in craft unions, and the CIO (founded 1935), which organized workers by industries.

History of the AFL. The organization that appeared in 1886 as the American Federation of Labor (AFL, or AF of L) had as its precursor the Federation of Organized Trades and Labor Unions, begun in 1881. The Knights of Labor, the most powerful industrial union of the era, sought to absorb the existing craft unions, to subject them to the loss of autonomy, and to involve them in industrial disputes in which their own direct interests were apparently not at stake. Against this tendency craft unions revolted under the leadership of Samuel Gompers, organizing themselves in 1886 in the loose federation that remained for half a century the sole unifying agency of the American labour movement.

In its beginnings, the American Federation of Labor was dedicated to the principles of craft unionism, so that its approximately 100 national and international unions each retained full autonomy over its own affairs as a labour organization. In return, each union received from the federation protection of the workers and industrial territory over which it claimed jurisdiction. Out of this policy grew bitter jurisdictional disputes among unions affiliated with the federation, but union membership grew.

The 1920s were the first period of economic prosperity that did not witness an expansion of unionism. During the Great Depression that followed the stock market collapse of 1929 and assumed catastrophic proportions in 1932 and early 1933, labour was too benumbed to do more than engage in a few desultory, des-

perate strikes. With the new administration of President Franklin D. Roosevelt came a new dawn for labour.

In the new political climate, with the government's patronage of unionism, the U.S. labour movement achieved unprecedented opportunities to expand its numbers. To facilitate this, the AFL occasionally chartered federal (plant-wide) locals, but, in general, the old craft unionists, representing a majority of the federation's membership, looked askance upon industrial unions in the mass-production industries as being disruptive of the labour movement.

History of the CIO. The craft-industrial issue came to a head in the 1935 convention of the American Federation of Labor. The industrial-unionist resolution stating that "in the great mass production industries . . . industrial organization is the only solution" was voted down. As a result of the convention's defeat of the industrial-union resolution, representatives of eight international unions announced on Nov. 9, 1935, the formation of the Committee for Industrial Organization (CIO). The AFL retaliated by warning and then, in August 1936, suspending all 10 unions (2 others had subsequently joined). But the CIO proceeded to organize such key industries as steel, rubber, and motor cars and reached agreements with such large corporations as U.S. Steel and General Motors. In the following years the CIO and the AFL engaged in a bitter struggle for leadership of American labour.

The CIO held its first convention at Pittsburgh, Pa., on Nov. 14-18, 1938, at which it adopted a new name (Congress of Industrial Organizations) and a constitution and elected John L. Lewis president.

Lewis pledged to resign as CIO president if Franklin D. Roosevelt, whom he had previously supported, was reelected in 1940. He kept his promise and was succeeded in that year by Philip Murray, who had served under Lewis in the United Mine Workers' union. In the following year the CIO organized the employees of the Ford Motor Company, the "little steel" companies (Bethlehem, Republic, Inland, and Youngstown), and other big industrial corporations that previously had refused to enter into signed agreements with it.

In 1943 the CIO established the Political Action Committee (PAC), which supported Roosevelt in his successful campaign for reelection in 1944.

Merger of the AFL and the CIO. The passage of the Taft-Hartley Act in 1947 and the growing conservatism in national labour policies implicit in the statute aroused unions to renewed political activity. The CIO joined the AFL in opposition to the new law, but political unity was only gradually translated into union unity. After the death of Philip Murray late in 1952, Walter P. Reuther, head of the CIO's United Automobile Workers, became president of the CIO; and three years later, in 1955, the AFL and the CIO merged, with George Meany, former head of the AFL, becoming president of the new federation (a post that Meany held until November 1979, a few months before his death).

The new combined union federation exhibited a concern for ethics when, in 1957, it expelled the Teamsters Union, after disclosures of corruption and labour racketeering in what was then the nation's largest union. (Not until 1987 was the Teamsters readmitted.)

The conservative Meany and the liberal Reuther never achieved more than icy cordiality, and in 1968 Meany succeeded in getting Reuther and several others expelled from the federation's executive board. Thereupon, Reuther's United Automobile Workers (UAW) promptly withdrew from the AFL-CIO. (Briefly, from 1968 to 1972, it allied with the Teamsters.) Reuther died in 1970, and, two years after Meany's retirement and Lane Kirkland's accession to the presidency of the

AFL-CIO in 1979, the UAW reaffiliated with the AFL-CIO.

From the AFL-CIO's creation in 1955, its affiliates' membership steadily expanded to reach a high of 17 million in the late 1970s. Membership shrank thereafter to about 13 million in the mid-1990s as employment in American manufacturing industries declined, a loss only partly offset by union growth in service industries such as government, education, and retail trade. Kirkland's elected successor in 1995 was John J. Sweeney, former president of the Service Employees International Union, who led a dissident slate committed to reversing the federation's declining membership and waning political power.

The general organization. The primary governing body of the AFL-CIO is the biennial convention, wherein national unions are allocated delegates in proportion to their membership. These delegates elect the president to a two-year term. The executive council, which meets at least three times a year, consists of the president, executive vice president, secretary-treasurer, and about 50 vice presidents, most of them presidents of national unions affiliated with the AFL-CIO. An executive committee of six vice presidents selected by the council meets more often with the president and secretary-treasurer to discuss policy matters. Also, a general board, consisting of the executive council and a principal officer of each affiliated union, meets at least once a year to decide policy questions referred to it.

The federation is supported by a per capita tax on affiliated unions and organizing committees. The federation engages in organizing efforts, educational campaigns on behalf of the labour movement, and political support of legislation deemed beneficial.

American Football League (AFL), American professional football organization, formed in 1959 to rival the older National Football League (NFL). Three earlier organizations of the same name did not fare well, each surviving only one or two years (1926, 1936-37, and 1940-41). AFL teams in 1960, the first season of play, were the Boston Patriots (later the New England Patriots), Buffalo Bills, Denver Broncos, Houston Oilers, New York Titans (later Jets), Oakland Raiders, Dallas Texans, and Los Angeles Chargers. The Los Angeles team moved to San Diego in 1961, and the team in Dallas became the Kansas City Chiefs in 1963. The Miami Dolphins were added to the league in 1966.

At first the NFL refused to recognize the new league. The two competed in bidding for players, but plans for merger were announced in 1966. In 1967 the first world-championship game, the Super Bowl, was played between the two league champions—Green Bay (NFL) defeated Kansas City (AFL), 35-10. That year the leagues engaged in a common draft of players, and in 1968 preseason interleague play was begun. In 1970 the old AFL teams, with Cleveland, Baltimore, and Pittsburgh of the NFL, became the American Conference of a new 26-team National Football League. See *Sporting Record: Football*.

American Friends Service Committee (AFSC), organization to promote peace and reconciliation through programs of social service and public information, founded by American and Canadian Friends (Quakers) in 1917. In World War I, the AFSC helped conscientious objectors to find work in relief projects and ambulance units as an alternative to military service. In World War II it broadened the scope of alternative-service possibilities to include duty in mental hospitals and other humanitarian work. In peacetime the AFSC continued such national and international programs as community development, racial reconciliation, aid to migrant workers, relief to civilians in war-torn areas, and refugee work. Its program of Voluntary International

Service Assignments (VISA) served as a model for the U.S. Peace Corps. In 1947 the AFSC was awarded the Nobel Prize for Peace jointly with the Friends Service Council, its British counterpart. The AFSC is financed by contributions from individuals, foundations, and, in some cases, governments of countries where its programs are carried out. Headquarters of the organization are in Philadelphia.

American Fur Company, enterprise incorporated in New York state (April 6, 1808) by John Jacob Astor, which dominated the fur trade of the central and western United States during the first third of the 19th century. The company absorbed or crushed its rivals during its search for furs in the Great Lakes region, Missouri River valley, Rocky Mountains, and Oregon. Explorations by the firm's traders and trappers, directed chiefly from its office in St. Louis, did much to prepare the frontier for settlement.

In 1810 Astor organized the Pacific Fur Company as a subsidiary to exploit the fur trade with China by way of the Pacific Northwest. The subsidiary's major post, Astoria, located at the mouth of the Columbia River in the Oregon Territory, was lost during the War of 1812, thus ending the enterprise. By 1834, when Astor sold his interest, the American Fur Company with its subsidiaries had become the largest commercial organization in the United States.

American Hebrew Congregations, Union of, oldest American federation of Jewish congregations, which, since its founding (1873) in Cincinnati, Ohio, has sponsored many programs to strengthen Jewish congregations and promote Jewish education on every level.

The union was organized by Rabbi Isaac Mayer Wise for the immediate purpose of establishing and supporting a seminary for the training of American-born rabbis, who, Wise felt, were the key to the future of Judaism in the United States. Two years later the union established Hebrew Union College, the first successful rabbinic seminary in the United States. In 1950 this college merged with the Jewish Institute of Religion of New York, founded in 1922 by Rabbi Stephen S. Wise.

Both institutions were long-time centres of Reform Judaism and are still supported by the union.

The union, now numbering some 600 Reform congregations (including several in Canada), is affiliated with the World Union for Progressive (Reform) Judaism and maintains headquarters in New York City.

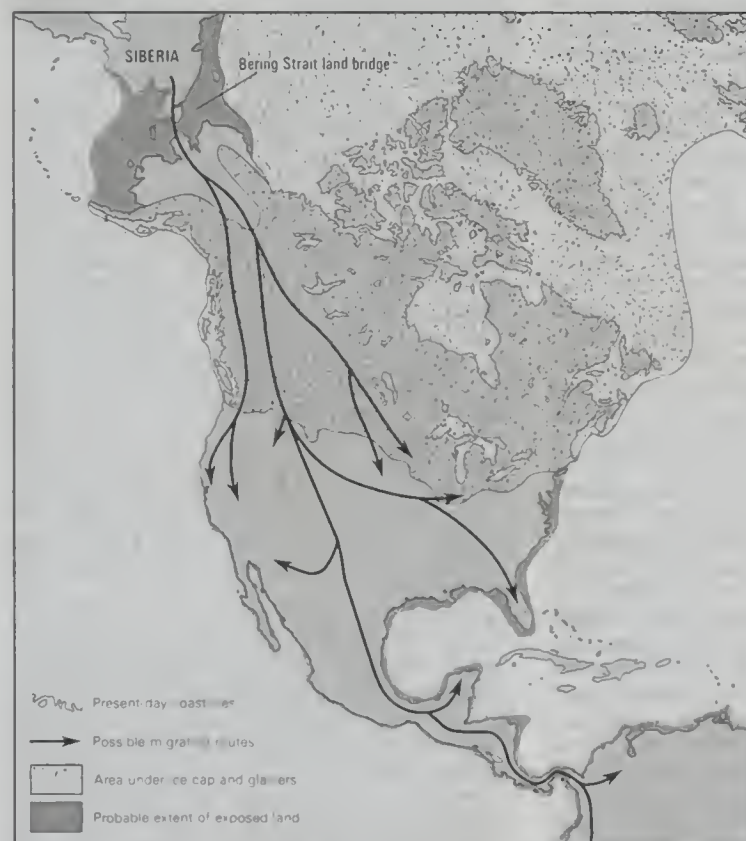

American Highland, interior plateau region of eastern Antarctica. It extends from Enderby Land in the west to Wilkes Land in the east and inland from Ingrid Christensen Coast and Amery Ice Shelf. The ice-capped upland, which averages 7,000-10,000 feet (2,000-3,000 m) above sea level, was discovered and named in 1939 by the American explorer Lincoln Ellsworth. It is the central part of a large area of eastern Antarctica claimed by Australia.

American Indian, also called AMERINDIAN, AMERIND, INDIAN, or NATIVE AMERICAN, member of any of the aboriginal peoples of the Western Hemisphere, with the exception of the Eskimos and Aleuts.

A brief treatment of the American Indians follows. For full treatment, see MACROPAEDIA: American Peoples, Arts of Native; American Peoples, Native; Pre-Columbian Civilizations.

The ancestors of the American Indians were nomadic hunters of Asian Mongoloid stock who migrated chiefly over the Bering Strait land bridge into North America probably during the last glacial period (about 20,000 to 35,000 years ago), though some debated estimates place the earliest migrations much earlier. These migrants shared certain cultural traits with their Asian contemporaries, including the use of fire, the domesticated dog, and particular rites. Other traits of Old World culture (e.g., animal husbandry, cultivation of certain plants, and the wheel and the plow) were absent in the Americas.

North America. The prehistoric settlers of North America belonged to a number of separate traditions. The Paleo-Indian hunting societies of the West, the Great Plains, and eastern North America had similar economies

The Bering Strait land bridge and the possible migration routes of the original settlers of North America

despite environmental differences. Their major food source was meat, and their clothing was made from animal hides. Archaeological remains of this tradition have been discovered on kill sites, areas that were used for slaughtering Pleistocene mammals. One of the most distinctive artifact types is the Clovis fluted projectile point, first discovered on a kill site near Clovis, N.M., and dated at approximately 9000 BC. The lance shaped point was used for killing mammoths.

Desert culture groups were dispersed throughout what is now the western United States—from Oregon to northern Mexico and from the Pacific Coast to the eastern Rockies. Many desert peoples were nomadic hunters and gatherers who dwelt in caves and rock shelters. Artifacts such as the milling stone, which was used for grinding seeds, have indicated the development of primitive agricultural techniques.

The Eastern Archaic period lasted from 8000 to 1500 BC. The cool, moist climate of the Great Plains and the Great Basin became hot and dry, resulting in the eventual extinction of Pleistocene animals. Societal patterns shifted to hunting and collecting economies, and by 6000 BC, coastal and riverine living was common. The Late Archaic was characterized by such technological developments as grooved stone axes, pestles, gouges and plummets; and systems of trade between tribes of different geographical areas evolved. The hunting economy during the Archaic period (8000–3000 BC) was distinguished by Plano projectile points, which were no longer fluted, and the primary game animal was bison. A moderation of climate between 3000 and 2000 BC (Late Plano) caused some groups to follow grazing game animals into Saskatchewan and Alberta and further north to the Arctic tundra zone.

Several societies in the southwestern United States began cultivating corn (maize) around 2000 BC, but it wasn't until after AD 1 that primitive agriculture had a substantial impact on Indian culture. In the Ohio and Illinois river valleys, corn cultivation played a crucial role in the sophisticated Hopewell economy (200 BC–AD 200). Surplus resources designated wealth for a particular, privileged group, and they were also used in elaborate burial rituals. A cold phase between AD 200 and 700 thwarted agricultural progress and resulted in cultural regression. In the Mississippi River Valley area, a village-based culture developed between 700 and 1200, distinguished by improved agricultural methods and intricate religious rituals. The latter involved ceremonial ornaments, which were produced in specialized centres, and an organized priesthood.

The Anasazi, Mogollon, and Hohokam were pre-Pueblo societies interspersed throughout the Southwest between 700 and 1200. Mogollon agricultural techniques—particularly the use of rainfall and stream diversion for watering crops—were improved by the Anasazi. The Hohokam culture of southern Arizona depended on irrigation to maintain an agricultural economy. A period of aridity from 1100 to 1300 inhibited cultural development and substantially depleted the size of these groups.

Pueblo culture began in the first millennium AD, when the techniques for building apartment houses of stone masonry and adobe were developed. Crops included several varieties of corn as well as long-staple cotton. The Classic Pueblo period (1050–1300) was characterized by significant advances in architecture and pottery. The great cliff houses had from 20 to 1,000 rooms and one to four stories, and polychrome pottery in specialized regional styles was created. The Regressive Pueblo period occurred between 1300 and 1700. Many apartment houses were abandoned during this

time of southward and eastward migration. The Modern Pueblo period began with the permanent settlements of the Spanish in the late 1600s. Some aspects of Pueblo culture and agricultural methods still survive.

In colonial times, European nations adopted different formal policies concerning the North American Indians. The Spaniards tried to Christianize native Americans and relocate them to designated areas, but the French were primarily interested in establishing trade relations with the Indians. Early English legislation prohibited unauthorized confiscation of Indian land, and the Proclamation of 1763 appropriated the entire area west of the Appalachians to native Americans. The latter policy held to the end of British rule and was adopted by the United States. The British North America Act of 1867, which created modern Canada, gave the new country exclusive legislative rights regarding the Indians and their lands.

The Indian Removal Act of 1830 marked the beginning of a long series of coercive policies. The discovery of gold in California in 1848 resulted in massive westward migration of the white man, and a number of treaties nullified Indian claims to land along the westward paths. Many gruesome wars ensued, including the Custer massacre by the Sioux and Cheyenne in 1876.

By 1887 most Indian peoples had been moved onto reservations. The Dawes General Allotment Act of that year caused them to lose approximately 134,400 square miles (348,100 square kilometres) of land. The Indian Reorganization Act of 1934 established programs for the advancement of native American peoples. Since the 1950s, new policies and social emphasis on civil rights resulted in the formation of Indian organizations and heightened national awareness of their problems.

Middle America. Indians entered Middle America, the area from Nicaragua to northern Mexico, more than 10,000 years ago. The development of farming techniques can be traced to around 4500 BC, and steady advances in the domestication of such staples as corn and beans led to the establishment of agricultural communities by 2000 BC. During the following centuries an increasingly stable food supply facilitated an evolution from minor settlements to large towns and inspired a growth in ceramics and many other arts.

During the first millennium AD, known as the Classic period, there arose such civilizations as the Maya, the people of which were unified by their ritual practices and ruled by a class of priests whose functions were thought to influence cycles of agricultural fertility. Among their most important divinities was the fertility god Tlaloc, whose symbol, the jaguar, is a recurrent motif on extant carvings. The jaguar was supplanted in later cultures by the traditionally more warlike eagle, and human sacrifice became a common religious practice. These religion-based societies were superseded, beginning around AD 1000 by the empires of the Toltecs and Aztecs, which flourished and expanded until the Spanish invasion of the 16th century. At its apex, the military strength of the Aztec Empire had brought nearly all of Middle America under its dominion.

From the initial race of immigrants several cultural subgroups evolved that can be classified according to the geophysical regions they inhabited. The coastal, desert, and mountainous terrain of the northwestern part of what is now Mexico supported one of these subgroups; another subgroup, the Tarascans, settled in the mountains of Michoacán. The Maya occupied parts of Guatemala, the Yucatan Peninsula, and Mexican Chiapas; the Aztecs were concentrated in the highlands of central Mexico and the site of present-day Mexico City; and a fifth subgroup developed on the coasts and highlands of southern Mexico.

Characteristically, Middle American Indian cultures have settled in small communities, of which the basic units are individual families. Male members and elders are dominant, and inheritance is channelled through the line of paternal descent, though lineage is acknowledged through both paternal and maternal relations. Communal activities are centred in the markets, where agricultural and crafted products are exchanged, and in the political bureaus, whose members also serve in a religious capacity. Each community is also represented by leaders on the national level. Though the primary form of worship is the Roman Catholicism introduced by the Spanish, remnants of earlier ritual practices persist in the devotion of cults to individual Christian saints and in a widespread adherence to animism, superstition, and divination.

Along with Catholicism, the Spanish conquest brought the tools and techniques of European industry and signalled a permanent reorganization of earlier social structures. During the first period of colonization, Jesuits set up religious reservations in northwest areas, and other sectors were settled in *encomiendas*, plots of land developed under Spanish supervision. Later, when the *encomiendas* were dissolved and the reservations removed from the auspices of the church, plantations, cattle herds, and mines became the economic centres of colonial society.

A revolution in 1821 achieved independence from European control for native-born Spaniards and others of mixed extraction in Mexico and Guatemala, who organized the policies of the new republics. During the following periods of industrialization and commercialization, Indian communities became increasingly isolationist in order to preserve their cultural integrity, despite the resulting economic deprivation. A subsequent revolution in Mexico in 1910 effected the removal of exclusionary social and economic policies and marked the beginning of the assimilation of Indian political, cultural, and economic contributions. Major programs were established for the solution of specifically Indian problems, and national attention was given to native Mexican art and tradition. Similar policies were adopted by Guatemala but were soon overthrown. By the late 20th century it appeared that a more complete integration of Indians into both urban and rural communities had occurred in Mexico than in Guatemala, though the native population of Guatemala continued to increase more rapidly.

South America. The civilizations of South America began, according to archaeological records, with the first migrations from North and Middle America at some point after 10,000 BC.

Among the first immigrants, the hunters and gatherers settled in what are now known as Tierra del Fuego, Argentina, southern Chile, the south-central plains of the Gran Chaco region, and portions of the central Andes, where they were later supplanted by more highly developed agricultural societies. The nomadic hunters organized themselves into small groups, which facilitated their frequent movement to areas of more plentiful game or more favourable climatic conditions. Like the agricultural inhabitants of the tropical forests, hunters formed groups based on kinship ties, and stratification within each group was determined by age and sex. Farming societies, located on the coasts of Brazil and Arawak, in the Greater Antilles, and in inland forest regions, however, were able to sustain larger and more stable social units through the successful cultivation of corn, beans and other indigenous crops, supplemented by hunting. Both the nomadic and the forested agricultural societies practiced the ritual magic, designed to attain control over their environment, that is characteristic of many preliterate cultures.

Other agrarian peoples, situated in the regions

bordering the Caribbean and in the northern Andes, developed more complex modes of social organization based on military and ritual leadership and supported by more technologically sophisticated farming practices. Warfare was important among these nations as a vehicle for social advancement within the tribe and as a means of supplying slaves and victims for ritual sacrifices. Rudimentary forms of centralized rule and an eventual transition from magic and ritual to the early stages of religion further distinguish these societies from the forested agricultural communities.

The most advanced of the native South American civilizations took root in the central Andes in approximately 2300 BC and evolved, culturally and technologically, for several thousand years. Beginning around AD 1000 they were organized into a number of kingdoms—the Chimú, the Tiwanaku (Tiahuanaco), and later, the Inca—that flourished until the Spanish invasion of the early 16th century. Occupying a region that extends from Peru through northern Chile, the Inca developed efficient irrigation works and a sophisticated, state-controlled system of food production, storage, and distribution that at the empire's apex supported a population of nearly 3,500,000. Its social hierarchy descended from a hereditary royal class, through strata of nobles and craftsmen, to the agricultural commons. Among the most conspicuous innovations of Inca civilization are the replacement of social regimentation by custom with a system of laws and the attainment of a high standard of artistic production.

These four sociocultural patterns correspond to stages in the historical development of the native South American nations. Several thousand years after the initial influx of a uniformly nomadic hunting population, advances in animal domestication, agriculture, and other technology—achieved in isolation—gave rise to increasingly complex social structures and fostered the emergence of centralized government and rigid class systems. The central Andean empires of the 11th century AD were the culmination of earlier regional prototypes whose origins can be traced to about 500 BC.

The effects of the 16th-century European conquest range from near extinction of some of the southern populations, through degrees of cultural depredation, to full absorption into colonial society. The native civilizations most severely depleted were those dwelling along major navigational routes, while some of the more remote Andean tribes have retained their culture up to the present and have even experienced a steady growth in population. The agricultural and political practices of the Inca Empire, however, were completely replaced by those of the Spaniards, and Inca religion was subjugated to Roman Catholicism. While the Inca aristocratic and artisan classes were to some extent absorbed into the colonial hierarchy, the native farming population was relegated to menial servitude. In less exploited regions, remnants of the Inca nation have preserved some of their cultural heritage and participated in economic exchanges with modern industrial centres. Other South American Indians, such as the Araucanians, successfully resisted Spanish domination until late into the 19th century but have since been suppressed and assimilated or assigned to reservations.

American Indian languages, languages spoken by the original inhabitants of the Western Hemisphere and their modern descendants. The American Indian languages do not form a single historically interrelated stock (as do the Indo-European languages), nor are there any structural features (in phonetics, grammar, or vocabulary) whereby American Indian languages can be distinguished as a whole from languages spoken elsewhere.

A brief treatment of American Indian lan-

guages follows. For full treatment, see *MACROPAEDIA: Languages of the World*.

In the pre-Columbian era, the American Indian languages covered both continents and the islands of the West Indies. There were, however, considerable differences in the distribution of the languages and language groups and in the size of the populations that spoke these languages.

In America north of Mexico, where the Indian population was thinly spread, there were a number of language groups—*e.g.*, the Eskimo-Aleut, Algonkian, Athabaskan, and Siouan—each of which covered large territories and included some 20 or more closely related idioms. Other language groups, however, were smaller and the areas containing them correspondingly more diverse in language. In California alone, for example, more than 20 distinct language groups were represented. These, according to Edward Sapir, exhibited greater and more numerous linguistic extremes than may be found in all of Europe. America north of Mexico, taken as a whole, had about 300 distinct languages, spoken by a population estimated at about 1,500,000.

Meso-America (Mexico and northern Central America) had a much larger Indian population—estimated at about 20,000,000—which spoke at least 80 languages. Some of these languages, *e.g.*, of the Aztecs of central Mexico and the Maya of Yucatan and Guatemala, belonged to large and complexly organized empires and probably accounted for most of the native population. Others were far more restricted in area and numbers of speakers. The area of greatest linguistic diversity appears to have been in southern Mexico and northern Central America.

South America had an aboriginal population of between 10,000,000 and 20,000,000 and the greatest diversity of languages—more than 500 languages. The bulk of the population was in the Andean region, where there was also a powerful Indian empire, that of the Incas. Their Quechuan languages spread beyond their original homeland in the southern Peruvian highlands and resulted in the extinction or reduction of many other Indian tongues.

European conquest and colonization ultimately led to the disappearance of many American Indian language groups and to radical changes in the groups that survived. A number of languages have become extinct: in the West Indies the aboriginal languages have almost entirely disappeared, and in America north of Mexico one-third of the aboriginal languages have become extinct. The situation is somewhat different in Meso-America and South America. Although there are no precise figures, a greater number of languages are still spoken, some of them by large populations.

Of the American Indian languages still spoken, many have only a bare handful of speakers. In America north of Mexico, more than 50 percent of the surviving languages have fewer than 1,000 speakers each. In communities as small as these, most people are bilingual, and the younger people, educated in English, often have little more than a superficial command of the native idiom. In short, even though the Indian population north of Mexico is actually increasing, most of the aboriginal languages are slowly dying out. Only a few languages are flourishing: Navaho, spoken in New Mexico and Arizona; Ojibwa, in the northern United States and southern Canada; Cherokee, in Oklahoma and North Carolina; and Dakota-Assiniboin, in the northern portions of the midwestern United States. Even in these groups, however, there is a high proportion of bilingualism.

In parts of South America and Meso-America there are still a number of widespread and flourishing language groups. Quechuan is one of these: it is estimated that this group of closely related dialects has several million speakers in Ecuador, Peru, and parts of Bolivia and Ar-

gentina. One of these extant languages, the dialect of Cuzco, Peru, was the principal language of the Inca Empire. The Indians of Mexico and Central America also still speak languages that date to the time of the Spanish conquest: Uto-Aztecan, a group of languages in central and parts of southern Mexico; the Mayan languages, spoken in Yucatan, Guatemala, and adjacent territories; and Oto-Manguan, of central Mexico. All three of these were languages of Indian empires before 1500, and both the Maya and Aztec peoples had writing systems.

The Tupí-Guaraní languages, spoken in eastern Brazil and in Paraguay, constitute a major pre-Columbian language group that has survived into modern times. Before the arrival of the Europeans, languages of this group were spoken by a large and widespread population. Tupí of Brazil became, after the conquest, the basis of a lingua geral, the medium of communication for Europeans and Indians throughout the Amazonian region. Guaraní similarly became a general language for much of Paraguay. Tupí was, by the early 21st century, gradually being replaced by Portuguese, but Guaraní remained an important second language of modern Paraguay, and an extensive folk literature has been created.

American Indian Movement (AIM), militant American Indian civil rights organization, founded in Minneapolis, Minn., in 1968 by Dennis Banks, Clyde Bellecourt, Eddie Benton Banai, and George Mitchell. Later, Russell Means became a prominent spokesman for the group. Its original purpose was to help Indians in urban ghettos who had been displaced by government programs that had the effect of forcing them from the reservations. Its goals eventually encompassed the entire spectrum of Indian demands—economic independence, revitalization of traditional culture, protection of legal rights, and, most especially, autonomy over tribal areas and the restoration of lands that they believed had been illegally seized.

AIM was involved in many highly publicized protests. It was one of the Indian groups involved in the occupation (1969–71) of Alcatraz Island, the march (1972) on Washington, D.C., to protest violation of treaties (in which AIM members occupied the office of the Bureau of Indian Affairs), and the takeover (1973) of a site at Wounded Knee (*q.v.*) to protest the government's Indian policy. With many of its leaders in prison, and torn by internal dissension, the national leadership disbanded in 1979. Local groups continued to function, however. A branch of AIM occupied part of the Black Hills (South Dakota) in the 1980s and obtained a court ruling that supported the Sioux's religious rights to the mountain region. In the early 21st century, AIM was active in the movement to ban sports teams from using Indian mascots and names.

American ivy: *see* Virginia creeper.

American League, one of the two associations designated as major leagues of professional baseball teams in the United States and Canada. The American League of Professional Baseball Clubs was founded in 1900, and in 1903 it was granted equal status by the older National League. The American League consists of 14 teams (including one Canadian team) aligned in three divisions: the Eastern, comprising the Baltimore Orioles, Boston Red Sox, New York Yankees, Tampa Bay Devil Rays, and Toronto Blue Jays; the Central, comprising the Chicago White Sox, Cleveland Indians, Detroit Tigers, Kansas City Royals, and Minnesota Twins; and the Western, comprising the Los Angeles Angels of Anaheim, Oakland Athletics, Seattle Mariners, and Texas Rangers. *See* *Sporting Record: Baseball*.

American Legion, organization of U.S. war veterans. It was founded in Paris on March 15–17, 1919, by delegates from combat and service units of the American Expeditionary Force. A national charter was granted to it by the U.S. Congress on Sept. 16, 1919; the charter was amended in 1942 to admit World War II veterans, in 1950 to include veterans of the Korean War, and again in 1966 to admit veterans of the Vietnam War. Nonpolitical and nonsectarian, the American Legion's membership requirement is honourable service and an honourable discharge. Its annual conventions are among the largest volunteer group meetings in the United States. The national headquarters are in Indianapolis, Ind.

One of the Legion's major concerns has always been care of disabled and sick veterans; it was instrumental in establishing hospitals and other services for veterans. It champions compensation and pensions for the disabled and for widows and orphans. The Legion successfully sponsored the creation of the U.S. Veterans Administration in 1930. In 1944 it played an important role in the enactment of the GI Bill of Rights for World War II veterans, and later in supporting similar legislation for Korean War veterans. These measures afforded college or vocational training to more than 10,500,000 veterans and enabled more than 5,600,000 veterans to purchase homes under the loan provisions of the act.

The Legion's Americanism and youth programs include projects in which groups of young people are given practical instruction in the functions of democratic government. It also sponsors thousands of Boy Scout troops and junior baseball teams. At the turn of the 21st century the total membership of the Legion was about 3,000,000 enrolled in 15,000 local posts, or groups, worldwide.

American lion: see puma.

American literature, the body of written works produced in the English language in the United States.

A brief treatment of the literature of the United States follows. For full treatment, see MACROPAEDIA: American Literature.

The origins of American literature lie in the 17th century, in the earliest colonial days of America, but it was only after the American Revolution that writers created a characteristically American literature. As the country developed its own distinctive national character and institutions, a literary tradition that would reflect those unique characteristics—social, economic, geographic, and linguistic—began to evolve. Some themes derived from the vast size of the country, its diversity of people, and its frontier.

The earliest American writings were based on European models and included not only fiction and poetry but also treatises on political and religious subjects. Of the poets, Anne Bradstreet and Edward Taylor wrote verse of high literary quality, and both were strongly influenced by English poets.

The two leading literary figures of the middle part of the 18th century, both of whom wrote nonfiction on subjects of political importance, were Benjamin Franklin and Thomas Paine. Franklin began his career as a journalist, and his popular almanac series entitled *Poor Richard's*, with its epigrams displaying both wit and common sense, spoke meaningfully to the colonial society and examined the conflict between the colonies and Great Britain. Paine's pamphlet *Common Sense* (1776) continued to inspire Americans throughout the Revolutionary period.

After the Revolution, the quest for a characteristic American literature began. Important writers of the early part of the 19th century in-

cluded Washington Irving, James Fenimore Cooper, and Edgar Allan Poe. Cooper's *Leatherstocking Tales* (1823–41) explored native American life and the frontier; Irving was a satirist; while Poe was the first great American poet and one of the inventors of the horror and detective story genres.

The first great period of American literature came between about 1830 and the beginning of the Civil War, when many writers were inspired by the mood of expansion and democracy that characterized the presidency of Andrew Jackson and the new spirit of hope and adventure that pervaded the country. They took as their subject the common man instead of the aristocratic figures found in English literature. The greatest of this group were the novelist Herman Melville, whose major work was the epic moral tale *Moby Dick* (1851); Nathaniel Hawthorne, author of such novels as *The Scarlet Letter* (1850); and the poet Walt Whitman, whose progressive and unconventional poetic autobiography was entitled *Leaves of Grass* (1855). During this time Harriet Beecher Stowe published her sensational *Uncle Tom's Cabin* (1852), the book Abraham Lincoln credited with starting the Civil War. Many Transcendentalists were also writers, notably the liberal philosopher Ralph Waldo Emerson and the individualist Henry David Thoreau, whose book *Walden* (1854) describes his experience of learning self-reliance. Emily Dickinson, who is probably America's greatest poet, also wrote during the Civil War period though its great issues had little impact on her brief, intense poetry.

Westward expansion during the 19th century resulted in the creation of much regional and humorous literature. The most important contributor to these genres was Mark Twain, whose *The Adventures of Tom Sawyer* (1876) and *The Adventures of Huckleberry Finn* (1884) described life along the Mississippi River. Toward the end of the 19th century there emerged a group of writers known as naturalists, who saw man as a victim of his fate and treated everyday subjects unromantically and in unflinchingly realistic detail. Among the greatest of this group were Theodore Dreiser, whose novels *Sister Carrie* (1900) and *The Financier* (1912) explored new social problems in a rapidly industrializing America, and Stephen Crane, whose masterful account of Civil War combat was *The Red Badge of Courage* (1895). Other notable writers of naturalist fiction included Frank Norris and Jack London.

Though she wrote in a somewhat different vein, Willa Cather, too, described the lives of immigrants and settlers of the plains. Henry James's novels of the same period were quite different, dealing with the psychological processes of upper-middle-class characters and the social and moral conflicts arising between Europeans and Americans. James's enormous productivity, mastery of style, and psychological subtlety made him perhaps the greatest of all American novelists. Edith Wharton, author of *The House of Mirth* (1905), took James as her model.

After World War I an important group of novelists and poets, collectively known as the "Lost Generation," reflecting their disillusionment with postwar society, won acclaim. The most important novelists of this interwar period included F. Scott Fitzgerald, Ernest Hemingway, William Faulkner, Sinclair Lewis, John Steinbeck, and Thomas Wolfe. Fitzgerald's *The Great Gatsby* (1925) and other books show the disillusionment and moral decay of American society in the 1920s. Hemingway's *A Farewell to Arms* (1929) and *For Whom the Bell Tolls* (1940) treat American expatriates in Europe during war or its aftermath. Also notable is the expatriate Modernist Gertrude Stein, who gained her greatest audience with her least typical work, *The Autobiography of*

Alice B. Toklas (1933). In such novels as *The Sound and the Fury* (1929) and *As I Lay Dying* (1930), Faulkner offered a fictional rural Mississippi county as a microcosm of human society.

The two most influential American poets of the first half of the 20th century, Ezra Pound and T.S. Eliot, both lived abroad for much of their careers, where they exercised a decisive influence on modern Anglo-American verse. Other notable poets of the period included Robert Frost, Carl Sandburg, William Carlos Williams, Wallace Stevens, and E.E. Cummings. Eugene O'Neill was the dominant figure in American drama during the interwar period, and one of the most important playwrights writing in any language during the century. His plays, among which are *Long Day's Journey into Night* (produced posthumously, 1956), generally display a tragic vision.

After World War II a number of fiction writers came to prominence who, in the aftermath of World War II and the coming of atomic weapons and the Cold War, tended to reinterpret traditional American values. Norman Mailer, James Jones, Joseph Heller, and Kurt Vonnegut, Jr., all documented American participation in World War II and its accompanying horrors and absurdities. A subtle, nuanced perception of how the war was felt at home was offered by Janet Flanner (Genêt), who wrote a periodic "Letter From Paris" for *The New Yorker* magazine. Fiction turned increasingly to fantasy and black humour in works by John Barth, Donald Barthelme, and Thomas Pynchon. The novels of the Russian-born Vladimir Nabokov were celebrated for their use of irony, parody, and linguistic innovation. Saul Bellow, Bernard Malamud, Philip Roth, and the Yiddish-language writer Isaac Bashevis Singer tended to treat the human condition more optimistically, emphasizing humour and forgiveness. Such writers as John Updike, J.D. Salinger, and John Cheever tended to focus on the sexual and moral confusion of the middle class. Among the writers who carried on the Southern tradition in American letters were Robert Penn Warren, William Styron, Eudora Welty, Flannery O'Connor, and Carson McCullers. Black American writers in the 20th century, notably Richard Wright, Ralph Ellison, James Baldwin, Alex Haley, and Toni Morrison, tended to explore themes of racism and race relations from a black point of view.

American poets of the mid-20th century were pioneers of new techniques and styles of expression. Of these, Robert Lowell, Theodore Roethke, Gwendolyn Brooks, Robert Penn Warren, Randall Jarrell, Allen Ginsberg, Sylvia Plath, Anne Sexton, and Adrienne Rich were among the most prominent. In drama, Arthur Miller and Tennessee Williams emerged to prominence in the years after World War II with such works as *Death of a Salesman* (1949) and *A Streetcar Named Desire* (1947), respectively. The playwrights of the second half of the 20th century were many. Edward Albee came to prominence in the 1960s and remained active throughout the next decades. Sam Shepard, David Mamet, Wendy Wasserstein, and many other dramatists made their mark on American theatre. At the turn of the 21st century, poetry, too, flourished in the hands of such writers as Robert Pinsky, Rita Dove, and Wendell Berry.

An increasing number of contributions in all genres focused on the immigrant experience in America. Several genres of popular literature—including science fiction and its various offshoots and detective novels, or murder mysteries, which saw a rise in female protagonists—appealed to a growing audience.

American Lutheran Church, Lutheran church in North America that in 1988 merged with two others to form the Evangelical Lutheran Church in America (q.v.).

American Medical Association (AMA), organization of American physicians, the objective of which is "to promote the science and art of medicine and the betterment of public health." It was founded in Philadelphia in 1847 by 250 delegates representing more than 40 medical societies and 28 colleges. The AMA includes 54 state or other medical associations; at the turn of the 21st century it had about 300,000 members. Its headquarters are in Chicago.

The AMA disseminates health and scientific information to its members and to the public and carries out a broad range of public health education programs via the mass media and lectures. It keeps its members informed of significant medical and health legislation, and it represents its profession before the U.S. Congress and other governmental bodies and agencies, advocating its own views in the process. It helps set standards for medical schools and internship programs.

In the AMA headquarters office are various departments concerned with a wide variety of medical topics, including geriatrics, maternal and child care, hospital facilities, medical education, nutrition, drugs, insurance plans, scientific exhibits, health in rural areas, mental health, the cost of medical care, the health of industrial workers, and medical publications. Much of the work of the AMA is carried out under the guidance of committees and scientific councils, which collect and analyze data concerning new medical discoveries and therapies. Such bodies include the council on medical education and hospitals (created in 1904), the council on drugs (founded in 1905 as the council on pharmacy and chemistry), the bureau of investigation (which investigates suspected quackery and charlatanry; founded in 1906), the chemical laboratory (1906), and the bureau of health education (1910).

Publications of the AMA include the weeklies *Journal of the American Medical Association* and *American Medical News* and several journals issued monthly and devoted to medical specialties.

American Mercury, American monthly literary magazine known for its often satiric commentary on American life, politics, and customs. It was founded in 1924 by H.L. Mencken and George Jean Nathan.

The periodical, under the editorship of Mencken, fast gained a reputation for Mencken's vitriolic articles directed at the American public (the "booboisie") and for Nathan's excellent theatrical criticism. Its fiction and other articles were the work of the most distinguished American authors and often the sharpest satirists of the day. Under Eugene Lyons, the *American Mercury* generated much of the pressure exerted on the U.S. Congress for funding of air power at the beginning of World War II. Later, the magazine passed through the hands of several publishers and over a period of time developed a militant anticommunist stand and a strident right-wing tone.

American Missionary Association (AMA), nondenominational society that works to develop educational opportunities for blacks and other minorities in the United States. The society originally grew out of a committee organized in 1839 to defend a group of African slaves who had mutinied against their Spanish owners and had brought their slave ship (*Amistad*) into U.S. waters to seek protection there. The AMA itself was incorporated in 1846 by the merger of three missionary anti-slavery societies whose goal was to establish missions for freed slaves overseas. After 1850 the AMA turned primarily to abolitionist activities. When the Union armies began freeing slaves during the American Civil War, the AMA opened schools for them. The AMA founded more than 500 schools for freed slaves in the South in the decades following the Civil War. These schools were actually

open to all students and often operated as integrated institutions during the Reconstruction period.

As the South recovered from the effects of the war and developed public school systems, the AMA gave its elementary and secondary schools to the public systems and instead concentrated on improving and expanding colleges for blacks in the South. Ten predominantly black colleges arose from the AMA's efforts: Atlanta University, Berea College, Dillard University, Fisk University, Hampton Institute (now Hampton University), Howard University, Huston-Tillotson College, Le Moyne College, Talladega College, and Tougaloo College. Six of these institutions are still closely affiliated with the AMA.

American mole shrew: see short-tailed shrew.

American Motors Corporation (AMC), American company that was primarily engaged in the manufacture of automobiles and other automotive products. It produced AMC compact cars, Jeeps, AM General trucks and buses, garden tractors and mowers, and various molded-plastic parts for cars, appliances, and other products. From 1936 until the sale of the division in 1968, Kelvinator appliances were a major product line. In 1987 AMC became a subsidiary of Chrysler Corporation.

American Motors descended from two pioneering automobile manufacturers—Nash Motors Company, incorporated in 1916, and Hudson Motor Car Company, founded in 1909. Nash Motors in 1916 had taken over the automotive business of the Thomas B. Jeffery Company, which had produced its first Rambler automobile in 1902. In 1937 the Nash company merged with Kelvinator Corporation, resulting in the Nash-Kelvinator Corporation, which produced both automotive vehicles and appliances. In 1950 Nash-Kelvinator produced the first modern American compact car, the Rambler. Meanwhile, the Hudson company produced three major makes of automobiles over the years: the Hudson, the Essex, and the Terraplane. In 1954 the company merged with Nash-Kelvinator, and the American Motors Corporation was created. In 1970 American Motors purchased the Jeep Corporation (then known as Kaiser-Jeep Corporation), a company dating to 1903. In 1979 AMC, as it was then known, began an ill-fated joint venture with the French automaker Renault, which the following year purchased a controlling stake in AMC. In 1987 the company was purchased by the Chrysler Corporation.

American Museum of Natural History, institute established in New York City in 1869. It is a major centre of research and education on the natural sciences. It pioneered in mounting field expeditions and in creating dioramas and other lifelike exhibits showing natural habitats and their plant and animal life. The museum's collections of research specimens number in the tens of millions, and its collections of fossils and of insects are among the largest in the world. It conducts research in anthropology, astronomy, entomology, herpetology, ichthyology, invertebrates, mammalogy, mineralogy, ornithology, and vertebrate paleontology, and it maintains permanent research stations in the Bahamas, New York, Florida, and Arizona. The museum has a 485,000-volume library on natural history, as well as photo, film, and manuscript collections. It also conducts a wide range of educational activities for the public. The American Museum-Hayden Planetarium, one of the world's largest, forms part of the museum; it has a 10,000-volume library on astronomy and a 75-foot- (23-metre-) diameter Sky Theater.

American Muslim Mission: see Islam, Nation of.

American organ (musical instrument): see melodeon.

American Party: see Know-Nothing Party.

American Philosophical Society, oldest extant learned society in the United States, founded under the impetus of Benjamin Franklin in 1743. At the turn of the 21st century, it had more than 850 members, elected for their accomplishments in any of five areas—the mathematical and physical sciences; biological sciences; social sciences; the humanities; and the arts, professions, and leaders in public and private affairs. Its headquarters are in Philadelphia, Pa.

From a group of young men called the Junto, formed in Philadelphia by Franklin in 1727, when he was only 21, there grew an interest in experiment and inquiry that resulted in his publication in 1743 of *A Proposal for Promoting Useful Knowledge Among the British Plantations in America*. This proposal was so favourably received that the American Philosophical Society was organized with Thomas Hopkinson (1709–51) as president and Franklin as secretary. In 1769 it was united with another scientific society founded by Franklin (the American Society), and Franklin was elected president (an office he held until his death in 1790); the new society was incorporated in 1780. The astronomer David Rittenhouse was the society's second president, and Thomas Jefferson was its third.

The American Philosophical Society occupies two buildings in Independence National Historical Park, Philadelphia—the Philosophical Hall (erected 1787–89) and the Library, a replica of the original home of the Library Company of Philadelphia (1798); the library and meeting rooms contain rich collections of manuscripts (almost 6,000,000 items) and books on American science and culture. The society's publications include *Memoirs*, *Proceedings*, *Transactions*, and *Year Book*.

American plum weevil: see plum curculio.

American Protective Association (APA), in U.S. history, an anti-Catholic, anti-immigrant group that briefly acquired a membership greater than 2,000,000 during the 1890s. A successor in spirit and outlook to the Pre-Civil War Know-Nothing Party, the American Protective Association was founded by Henry F. Bowers at Clinton, Iowa, in 1887. It was a secret society that played upon the fears of rural Americans about the growth and political power of immigrant-populated cities.

Following William McKinley's election as president in 1896 and the restoration of agricultural prosperity in the Midwest, membership dwindled. By 1900 the APA no longer exerted any noticeable political power, and it had disappeared entirely by 1911.

American Quarter horse, breed of horse developed for racing a quarter mile. Originating in the American colonies as a fast, quarter-mile racer, it was overshadowed by the Thoroughbred but eventually found acceptance in the western and southwestern United States as a stock horse. It was bred for performance and had considerable Thoroughbred blood as well as traits of other lines. Important sires include Janus, an English Thoroughbred imported to Virginia in 1756; Steel Dust (b. 1843); and Peter McCue (b. 1895), called the most influential sire in improving the breed.

Modern American Quarter horses are short and stocky, with a heavy muscular development and deep, broad chests. Since these horses are used to cut cattle from herds, fast starting, turning, and stopping ability and speed for short distances are essential qualities. Colours are variable; height of mature animals

American Quarter horse

By courtesy of the American Quarter Horse Association, photograph: Sheryl Curtis

varies from 14.3 to 16 hands (about 57 to 64 inches, or 145 to 163 cm) and weight from 950 to 1,200 pounds (431 to 544 kg). They have a calm, cooperative temperament.

For years little attempt was made to develop a distinct breed. In 1940 the American Quarter Horse Association was organized, and in 1950 it was reorganized to include other Quarter horse organizations. It controls the *American Quarter Horse Stud Book and Registry*.

American Railway Express Company: see REA Express, Inc.

American Renaissance, also called *NEW ENGLAND RENAISSANCE*, period from the 1830s roughly until the end of the American Civil War in which American literature, in the wake of the Romantic movement, came of age as an expression of a national spirit.

The literary scene of the period was dominated by a group of New England writers, the "Brahmins," notably Henry Wadsworth Longfellow, Oliver Wendell Holmes, and James Russell Lowell. They were aristocrats, steeped in foreign culture, active as professors at Harvard College, and interested in creating a genteel American literature based on foreign models. Longfellow adapted European methods of storytelling and versifying to narrative poems dealing with American history. Holmes, in his occasional poems and his "Breakfast-Table" series (1858-91), brought touches of urbanity and jocosity to polite literature. Lowell put much of his homeland's outlook and values into verse, especially in his satirical *Biglow Papers* (1848-67).

One of the most important influences in the period was that of the Transcendentalists (see Transcendentalism), centred in the village of Concord, Mass., and including Ralph Waldo Emerson, Henry David Thoreau, Bronson Alcott, George Ripley, and Margaret Fuller. The Transcendentalists contributed to the founding of a new national culture based on native elements. They advocated reforms in church, state, and society, contributing to the rise of Free Religion and the Abolition movement and to the formation of various utopian communities, such as Brook Farm. The Abolition movement was also bolstered by other New England writers, including the Quaker poet John Greenleaf Whittier and the novelist Harriet Beecher Stowe, whose *Uncle Tom's Cabin* (1852) dramatized the plight of the black slave.

Apart from the Transcendentalists, there emerged during this period great imaginative writers—Nathaniel Hawthorne, Herman Melville, and Walt Whitman—whose novels and poetry left a permanent imprint on American literature. Contemporary with these writers but outside the New England circle was the Southern genius Edgar Allan Poe, who had a strong impact on European literature.

American Revolution: see United States War of Independence.

American round, in archery, a target-shooting event consisting of five ends (six arrows each), shot from distances of 60, 50, and 40 yards (55, 46, and 37 m). Two American rounds and two York rounds, consisting of 12 ends of 6 arrows each, constituted the U.S. men's championship until 1968, when other combinations of rounds were introduced. In the junior American round for boys and girls, 30 arrows each are shot from distances of 50, 40, and 30 yards.

American Saddlebred horse, breed of riding horse possessing several easy riding gaits and great vigour and style. It is the prevailing riding horse of horse shows in the United States. The Thoroughbred, Morgan, Standardbred, Arabian, pacers, and easy riding horses of a mixed background contributed various qualities to this American breed. Selection for an easy riding gait, style, and beauty, accompanied by line breeding, shaped them into a breed.

Average height and weight for the breed are 15 to 16 hands (about 60 to 64 inches, or 152 to 163 cm) and 1,000 to 1,200 pounds (about 450 to 540 kg). The American Saddlebred horse is characterized by a short, strong back; the barrel is rounder than in most light breeds. The neck is long, slender, and well-arched; it blends smoothly into a well-shaped shoulder. The croup is long and almost level. American Saddlebred horses have most of the solid colours with white markings and are shown under flat saddles as either three- or five-gaited horses. The three gaits are the walk, trot, and canter. The five-gaited horse has these three gaits plus the rack and one slow gait. The slow gait is usually the stepping pace but may be the running walk or foxtrot. Three-gaited horses are shown with a roached (clipped, standing) mane and a clipped tail. Five-gaited horses are shown with a full mane and tail. American Saddlebreds are also used as pleasure horses, as driving horses, and quite often as hunters and jumpers.

American Saddlebred horse

By courtesy of the American Saddlebred Association

American Saddlebred horses were recognized as a distinct breed in 1891, when the American Saddle Horse Breeders' Association (now American Saddlebred Horse Association, Inc.) was organized. It publishes the *American Saddle Horse Register* and *The American Saddlebred* magazine.

American Samoa, officially TERRITORY OF AMERICAN SAMOA, unincorporated territory of the United States in the central Pacific Ocean. It comprises the eastern Samoan islands of Tutuila, Aunuu (Aunu'u), and Rose; three islands (Tau [Ta'u], Olosega, and Ofu) of the Manua (Manu'a) group; and Swains Island. The territorial capitals are Fagatogo (legislative and judicial seat) and Utulei (executive), both of which are villages within the urban agglomeration of Pago Pago, on Tutuila. Area 77 square miles (199 square km). Pop. (2000 est.) 65,400.

American Samoa

A brief treatment of American Samoa follows. For full treatment, see *MACROPAEDIA: Pacific Islands: American Samoa*.

The land. The largest island, Tutuila, accounts for over two-thirds of American Samoa's total land area and lies in the westernmost region of the island group, less than 50 miles (80 km) from the Samoan (formerly Western Samoan) island of Upolu. The Manua island group, about 60 miles (97 km) east of Tutuila, constitutes the second largest land area; Tau is the largest of the three islands in the group. The remaining islands are quite small; Aunuu lies off the southeastern tip of Tutuila, and Rose Island is an uninhabited coral atoll about 250 miles (400 km) east of Tutuila. Swains Island is a privately owned coral atoll some 280 miles (450 km) northwest of Tutuila.

Except for the low-lying coral atolls of Swains and Rose, the islands are rocky and were formed from the remains of extinct volcanoes. Central mountain ranges dominate the landscapes of Tutuila and the islands of Manua. The highest peak of Tutuila is Mount Matafao (2,141 feet [653 m]), but the most noted is Mount Pioa (1,847 feet [563 m]), known as the "Rainmaker" because of its frequent cloud cover. Tau is a cone-shaped island, rising to 3,170 feet (966 m) at Lata Mountain, the highest peak in the territory. The islands are surrounded by coral reefs, which in some cases form barriers that create lagoons. The mountain ranges and the coral reefs tend to limit the width of the coastal plains in most areas.

The tropical climate is moderated by oceanic trade winds and frequent rains; Pago Pago receives about 200 inches (5,000 mm) of rain annually. Temperatures are remarkably constant throughout the year. Daily lows average about 68° F (20° C), and afternoon highs reach about 90° F (32° C). About 70 percent of the islands' land area is covered by rain forests with tall ferns and trees such as the *Barringtonia asiatica*, the breadfruit, the pandanus, and abundant coconut trees.

The people. Samoan or part-Samoan individuals form the overwhelming majority of the population. They are a Polynesian people whose language belongs to the Oceanic subgroup of the Austronesian (Malayo-Polynesian) language family. Most American Samoans also speak English. Citizens of American Samoa are considered U.S. nationals, but not U.S. citizens. Traditional religions have essentially disappeared on the islands. Nearly three-fourths of the population is Protestant, and most of the remainder is Roman Catholic.

About 95 percent of the total population is concentrated on Tutuila, and more than half of that island's residents live on the eastern part of the island, which contains the largest settlement, Pago Pago. Virtually all the remaining population lives on the islands of Manua. Since the 1950s thousands of American Samoa residents have migrated to Hawaii and the continental United States.

The economy. Although fishing and tourism are major industries, the U.S. administration is the main employer in American Samoa. The territory's gross national product (GNP) is growing about as rapidly as the popu-

lation; the GNP per capita is one of the highest among the Pacific Islands. Fish are caught for processing and canning in American-owned factories, and canned tuna accounts for almost all of American Samoa's export income. Only about one-fifth of the islands' total land area is arable, and about half the arable land is under permanent cultivation. Agricultural production is primarily used for domestic consumption. The principal crops are coconuts, taro, yams, bananas, papayas, pineapples, and breadfruit.

Local commerce caters to the tourist trade, and Pago Pago is an important mid-Pacific stopover for passenger airplanes. The American Samoan government, which employs one-third of the islands' labour force, is financed by local revenues and by the U.S. government. The United States is the source of the vast majority of American Samoa's imports. Tutuila has most of the islands' roads and an international airport, while smaller airports operate from Tau and Ofu islands. Pago Pago is the major port.

Government and social conditions. The structure of the American Samoan government closely resembles that of the United States. The executive is headed by an elected governor, who until 1977 was appointed by the U.S. Department of the Interior. The legislature, or Fono, has a Senate, whose members are chosen by councils of chiefs, and a House of Representatives, whose members are popularly elected. Education in American Samoa is conducted mostly in English. The American Samoan Community College offers a wide range of vocational training. In 1972 the government instituted a social-security program for its workers; the fishing industry followed suit. A hospital on Tutuila is supplemented by health clinics throughout the islands.

History. The islands that are now American Samoa were probably inhabited by Polynesians more than 2,500 years ago. Prior to European contact and exploration, Tutuila was a subordinate district of the island of Upolu (now part of Western Samoa), and the Manua Islands were ruled by their own powerful chief. The Dutch navigator Jacob Roggeveen sighted the Manua Islands in 1722 and made contact with the islanders. French explorers arrived in 1768, and, in 1787, 11 members of a French expedition were massacred. For the next 40 years European explorers avoided the islands, during which time the islands became a haven for runaway sailors and escaped convicts. The first missionaries of the London Missionary Society arrived on the islands in the 1830s, and more Christian missionaries followed as Tutuila and later the Manua Islands were brought under missionary influence.

In January 1872 the United States signed a treaty with the kingdom of Samoa obtaining rights to establish a naval station at Pago Pago. In 1889 the United States, Britain, and Germany agreed to Samoan neutrality and created a tripartite protectorate over the islands. A convention in 1899 recognized the paramount interests of the United States in the islands east of longitude 171° W and of the Germans in the islands west of the meridian. By deeds of the high chiefs, the eastern group was ceded to the United States in 1904 but was not accepted by the U.S. Congress until 1929 (Swains had been granted to the United States by Britain in 1925). The islands were placed under the jurisdiction of the U.S. Navy until 1951, when their administration was transferred to the U.S. Department of the Interior. In 1960 a constitutional convention of American Samoans approved the first constitution of the territory. In 1978 the territory's first elected governor took office.

American spikenard (plant): *see* spikenard.

American States, Organization of (OAS), organization formed to promote economic, military, and cultural cooperation among its

members, which include almost all of the independent states of the Western Hemisphere. (Cuba's membership was suspended in 1962.) The OAS's main goals are to prevent any outside state's intervention in the Western Hemisphere and to maintain peace between the various states within the hemisphere.

The OAS grew out of an earlier U.S.-sponsored international organization for the Western Hemisphere, the Pan-American Union, which held a series of nine Pan-American conferences from 1889-90 to 1948 to reach agreement on various commercial and juridical problems common to the United States and Latin America. (*See* Pan-American conferences.) In World War II, most Latin American nations sided with the United States and declared war against the Axis powers. After this global conflict, all 21 independent nations of the Western Hemisphere agreed in 1947 on a formal mutual-defense pact called the Inter-American Treaty of Reciprocal Assistance. By 1948, with the start of the Cold War, it had become apparent that a stronger security system was needed in the Western Hemisphere to meet the perceived threat of international communism. At the urging of the United States, the OAS Charter was signed on April 30, 1948, at the conclusion of the Ninth Pan-American Conference held in Bogotá, Colombia. The aims of the organization were to strengthen the peace and security of the Western Hemisphere, to promote the peaceful settlement of disputes among member states, to provide for collective security, and to encourage cooperation in economic, social, and cultural matters. Most of the newly independent nations of the Caribbean joined the OAS in the 1960s, and the last major holdout, Canada, joined in 1990. The OAS has traditionally been strongly anticommunist in its orientation.

The founding of the OAS was based on the general acceptance of the principles of the U.S. Monroe Doctrine by the countries of the Western Hemisphere, especially the principle that an attack upon one American state would be considered as an attack upon all. The OAS attempted to "continentalize" the Monroe Doctrine, creating obligations for the other states without restricting the right of the United States to take immediate action in self-defense.

The General Secretariat is the administrative backbone of the OAS and is headed by a secretary-general elected to a five-year term. The chief policy-making body of the OAS is the General Assembly, which holds annual meetings at which member states are represented by their foreign ministers or chiefs of state. The General Assembly controls the OAS's budget and supervises various specialized organizations. In case of attack or an act of aggression within or between member states, the Permanent Council, composed of an ambassador from each member state, acts as the provisional organ of consultation until all the member states' ministers of foreign affairs can assemble. At this consultation meeting of foreign ministers, collective action cannot be undertaken without the approval of two-thirds of the foreign ministers present. The General Secretariat and the Permanent Council are based in Washington, D.C.

The OAS provided the framework for a truce and subsequent resolution of the Soccer War (1969) between Honduras and El Salvador, and it has settled border conflicts between various other Latin American nations since the late 1940s. After Cuba declared itself Marxist-Leninist in 1961, its membership in the OAS was suspended, and the OAS supported U.S. President John F. Kennedy in 1962 in the quarantine against the shipment of Soviet missiles to Cuba. In the face of Cuban attempts to subvert neighbouring countries, the OAS ordered trade sanctions and the breaking of diplomatic ties with that nation from 1964 to

1975. The OAS supported the United States' unilateral military intervention in the Dominican Republic in 1965 to prevent a left-wing government from coming to power. In the wake of the U.S. invasion, the OAS created an inter-American military force that kept the peace in the Dominican Republic until new elections were held there in 1966.

The left-wing Sandinista movement that held power in Nicaragua between 1979 and 1990 was not opposed by the OAS because it did not seem to offer any potential for Soviet intervention in the Western Hemisphere, despite the United States' claims to the contrary. Since the end of the Cold War in the early 1990s, the OAS has become more active in encouraging democratic government in member states, and it has become a leader in observing and monitoring elections to safeguard against fraud and irregularities. In the economic and social field, its most notable achievement was its adoption of the Charter of Punta del Este (1961), establishing the Alliance for Progress. The Inter-American Court of Human Rights was established at San José, Costa Rica, in 1979.

American Stock Exchange (AMEX), second largest stock exchange in the United States. Originally known as "the Curb" because its transactions took place outdoors during much of its existence, the marketplace is believed to have begun about 1849. By 1908 it was known officially as the New York Curb Agency. From 1929 to 1953 it was known as the New York Curb Exchange, and in 1953 its name was changed to its present form. The market first moved indoors in 1921, at a location it still occupies in New York's Wall Street area. For a number of years it was a marketplace for securities not considered reputable enough for listing on the New York Stock Exchange, but it is now considered an equally respectable exchange with its own listing requirements for securities and admissions requirements for members.

American University, private, coeducational institution of higher learning in Washington, D.C. The American University was incorporated in 1891 as a graduate school and research centre with ties to the Methodist church. It was chartered by an act of the U.S. Congress in 1893 but did not begin to function until 1914, when graduate-level courses were begun. An undergraduate division was founded in 1925, and in 1949 the university became affiliated with the Washington College of Law. The American University has schools of public affairs, international service, and communication, colleges of education and of arts and sciences, the Kogod College of Business Administration, and the Washington College of Law, all of which offer professional degrees. Students can study abroad at centres located throughout Europe and South America or in Beijing. Total enrollment is approximately 9,400.

American yew, also called CANADA YEW, DWARF YEW, GROUND HEMLOCK, or CREEPING HEMLOCK (*Taxus canadensis*), a prostrate, straggling evergreen shrub of the family Taxaceae, found in northeastern North America. American yew also is a lumber trade name for the western yew. The American yew, the hardiest of the yew species, provides excellent ground cover in forested areas. Usually growing about 1 m (about 3 feet) high, it has small yellowish green leaves that taper abruptly to a tiny point.

Americana, formerly (1868–1938) VILA AMERICANA, city, in the highlands of east-central São Paulo *estado* ("state"), Brazil. Americana lies near the Piracicaba River at 1,732 feet (528 m) above sea level. It was settled in 1868 by immigrants from the former Confederate States of America. The settlement was made a seat of a municipality in 1924. Agriculture is the main local source of income, and foodstuffs are processed in the city. Highways and railroads link Americana to São Paulo, the state capital, 68 miles (109 km) to the southeast. Pop. (1991 prelim.) 153,592.

Americanization, those activities that were designed to prepare foreign-born residents of the United States for full participation in citizenship. It aims not only at the achievement of naturalization but also at an understanding of and commitment to principles of American life.

Before the outbreak of World War I in 1914, the American public generally took it for granted that the constant flow of newcomers from abroad brought strength and prosperity to the country. The metaphor of the "melting pot" had been introduced to symbolize the mystical potency of the great democracy, whereby people from every corner of the earth were fused into a harmonious and admirable blend. After the war began, however, American reactions to European hostilities produced an intense awareness of the aliens and "foreigners" in their midst. Assimilation, it was believed, must be achieved by deliberate, purposeful means.

The Americanization movement that came into being was primarily a program of education, in schools, voluntary associations, and various public programs. The teaching of foreigners became a favourite form of patriotic service, particularly after the entry of the United States into the war.

In its earliest days the program was directed toward the correction of the most obvious deficiencies. The core of the curriculum was the English language, American history, and the governmental structure of the United States, understanding of which was necessary for naturalization. Those who were interested in teaching other subjects began to capitalize on the popularity of the movement. Soon the offering included courses in millinery, cooking, social amenities, and the care of children, all presented, of course, as essential elements of American culture.

Enthusiasm for Americanization persisted throughout World War I and was prolonged into the postwar period. Gradually, however, popular interest diminished. Wartime apprehensions subsided, and new legislation severely limited the influx of immigrants. Before long, Americanization became no more than a fairly obscure but continuing effort to prepare people for naturalization by teaching them English, civics, and history or even English alone.

Meanwhile, there had developed a thorough reexamination of the concept of Americanization. The idea of the melting pot and the early belief that all foreigners should be transformed into typical Americans began to appear naive. Who is the typical American? Are American cultural habits (as defined in any particular curriculum) necessarily better than the way of life with which the foreign resident is familiar? The United States was built by people who came from many backgrounds; is not the effort to impose conformity itself un-American? These and other questions proved hard to answer in the 1920s. So deeply did the disillusionment penetrate that within less than a decade after the Armistice, "Americanization" was a term to be shunned, not used.

In the years that followed, it never regained its earlier lustre.

In place of the old idea of supplanting all foreign traits by a standard pattern there grew up the idea of cultural "pluralism." It was argued by some that assimilation in its accepted sense was not a desirable goal but that American civilization would benefit by preserving many separate cultures side by side. Still others contended that this pluralism would gradually disappear over the years, that the American character was still in the process of formation, and that, as this character gradually emerged, it would be enriched by the blending of the admirable features of the various foreign nationalities.

Americans for Democratic Action (ADA), a liberal independent political organization in the United States. It was formed in 1947 by a group of labour leaders, civic and political leaders, and academics who were liberal in their views on national affairs, internationalist in world outlook, and anticommunist in conviction. The ADA is devoted to the propagation of liberal ideas, the election of liberal public officials, and the passage of liberal legislation. The ADA reached the height of its influence after John F. Kennedy's election to the presidency in 1960, when a number of ADA leaders and members were appointed to key positions in his administration. The ADA supported the domestic legislative agenda of Kennedy's successor, Lyndon B. Johnson, but broke with him over the issue of American involvement in the Vietnam War, which the ADA opposed. The ADA has traditionally cultivated close ties with elements of the Democratic Party. It is headquartered in Washington, D.C.

Americas, also called AMERICA, the two continents, North and South America, of the Western Hemisphere. The climatic zones of the two continents are quite different. In North America, subarctic climate prevails in the north, gradually warming southward and finally becoming tropical near the southern isthmus. In South America, the climate in the north is tropical, becoming cooler southward, and finally becoming a cold, marine climate at Cape Horn.

The Americas can be roughly divided into two major cultural regions: Latin America, which includes North America south of the Rio Grande, the Hispanic islands of the West Indies, and all of South America; and Anglo-America, which includes Canada and the United States. The term Middle America (or Mesoamerica) is sometimes used to designate Mexico, Central America, and the West Indies collectively.

The name America is derived from that of the Italian explorer and friend of Christopher Columbus, Amerigo Vespucci, who made several voyages to the Western Hemisphere and, perhaps more important, described his travels there in letters to friends in Italy. One of these letters, published in 1504, used the term "Mundus Novus" ("New World") in referring to South America. The letter circulated from hand to hand, and a copy reached the German cartographer Martin Waldseemüller, who was apparently unaware of Columbus' voyage of 1498, during which he had discovered the continent of South America. Waldseemüller included some of Vespucci's writings in his *Cosmographiae introductio* (1507; *Introduction to Cosmography*) and observed that "another fourth part [of the inhabited earth] had been discovered by Americus Vesputius," and he suggested that the new land be called America, in recognition of that explorer's voyages. Waldseemüller's book was widely read, and the new appellation was eventually universally accepted.

Americas, pony of the, riding-pony breed used as a child's mount, developed in the

United States in the 1950s by crossing ponies with Appaloosa horses. To qualify for registration with the Pony of the Americas Club, a pony must have the dappled Appaloosa (*q.v.*) patterning and measure from 11.2 to 13.2 hands (46 to 54 inches, or 117 to 137 cm) tall at maturity.

America's Cup, one of the oldest and best-known trophies in international sailing yacht competition. It was first offered as the Hundred Guinea Cup in 1851 by the Royal Yacht Squadron of Great Britain for a race around the Isle of Wight. The cup was won by the *America*, a 100-foot (30-metre) schooner from New York City, and subsequently became known as the America's Cup. The American winners of the cup donated it to the New York Yacht Club in 1857 for a perpetual international challenge competition. In 1987 the San Diego Yacht Club took control of the U.S. competition.

Since the 1920s the America's Cup race has been between one defending vessel and one challenging vessel, both of which are determined in separate series of elimination trials. Each competing vessel must be designed, built, and, insofar as possible, outfitted solely in the country that it represents. The original terms of the America's Cup donation imposed many

(Left) *America*, about 1885, and (right) the America's Cup

By courtesy of (right) the New York Yacht Club; photograph (left), Morris Rosenfeld & Sons, Inc.

disadvantages on challenging yachts. Not until 1956 was a clause eliminated that required a challenger to sail on its own bottom to the scene of the contest, forcing a heavier style of construction than that of the defender. Until 1995, the America's Cup competition was a best four of seven races; from that year it required five of nine races to win. From 1958 to 1987 each race was run over a six-leg 24-mile (39-kilometre) course by yachts of the so-called 12-metre class. (No measurement on the 12-metre yacht was actually 12 m. The "12" was a result of a complicated mathematical formula used in the yacht's construction.) In 1983, after American yachts (sponsored by the New York Yacht Club) had successfully defended the cup 24 times without a loss since the first defense in 1870, the Australian yacht *Australia II* won the cup. In the next race, in 1987, the Americans (now from San Diego) regained the cup. The controversial race of 1988, between the winning American 60-foot (18-metre) catamaran and a New Zealander 132-foot (40-metre) monohull, had to be decided in the courts and provoked a redefinition of the rules governing future races. For 1992, a new and faster yacht was designated as the International America's Cup Class (IACC)—75 feet (23 m) in overall length—to race over an eight-leg 22.6-mile (36.4-kilometre) course. The 1995 event was run over a six-leg, 18.55-nautical-mile (34.4-kilometre) course. It was won by the Royal New Zealand Yacht Squadron, only the second victory by a non-American challenger in the history of the competition. See *Sporting Record: Yachting*. See also yacht.

americium (Am), synthetic chemical element (atomic number 95) of the actinide series in Group IIIb of the periodic table. Undetected in nature, americium (as the isotope americium-241) was artificially produced from plutonium-239 (atomic number 94) in 1944 by Glenn T. Seaborg, Ralph A. James, Leon O. Morgan, and Albert Ghiorso in a nuclear reactor. It was the fourth transuranium element to be discovered (curium, atomic number 96, was discovered a few months previously). The metal is silvery white and tarnishes slowly in dry air at room temperature. The isotope americium-241 is the most important because of its availability; it has been prepared in kilogram amounts from plutonium and has been used industrially in fluid-density gauges, thickness gauges, aircraft fuel gauges, and distance-sensing devices, all of which utilize its gamma radiation. All isotopes of americium are radioactive; the stablest isotope, americium-243, has proved more convenient for chemical investigations in view of its longer half-life (7,370 years as compared with 458 years for americium-241).

Americium reacts with oxygen to form the dioxide AmO_2 and with hydrogen to form the hydride AmH_2 . There is some evidence that the ion Am^{2+} has been prepared in trace amounts, its existence suggesting that americium is similar to its lanthanide homologue, europium, which can be reduced to its divalent state. Americium has four oxidation states, from +3 to +6, in acidic aqueous solution with the following ionic species: Am^{3+} , pink; Am^{4+} , rose (very unstable); AmO_2^+ , yellow; and AmO_2^{2+} , light tan. In the common tripositive state, americium is very similar to the other actinide and lanthanide elements.

atomic number	95
stablest isotope	243
melting point	above 850° C (1,550° F)
specific gravity	13.67 (20° C)
valence	2,3,4,5,6
electronic config.	2-8-18-32-25-8-2 or (Rn)5f ⁷ 7s ²

Americus, city, seat (1831) of Sumter county, southwest-central Georgia, U.S., on Muckalee Creek. Founded in 1830, it was named for Amerigo Vespucci or, legend says, for the "merry cusses" who were its first settlers. It is a trade and processing centre for agriculture, livestock, and timber, with some light industry, and kaolin and bauxite are mined nearby. To the northeast is Andersonville National Historic Site, where many Union soldiers who were prisoners of war died in a Confederate camp during the American Civil War (1861–65). The aviator Charles A. Lindbergh made his first solo flight at nearby Souther Field. Americus is the seat of Georgia Southwestern College (1906). Plains, the hometown of Jimmy Carter, former president of the United States, is 10 miles (16 km) west-southwest. Inc. 1855. Pop. (2000) 17,013.

Amerindian, also called **AMERIND**: see American Indian.

Amersfoort, *gemeente* (commune), in Utrecht *provincie* ("province"), central Netherlands, on the Eem (formerly Amer) River. The

The Koppelpoort across the Eem River, Amersfoort, Neth.

Van Phillips—Shostal

site (the name means "ford on the Amer") was fortified in the 12th century. Its medieval street pattern and some old walls remain, as does the Koppelpoort (a water gate dating from about 1400 and spanning the Eem). Landmarks include the 13th–16th-century Sint Joris Church and the Gothic Tower of Our Lady (the bell tower of a church destroyed in 1787). There is a regional museum, a government archaeological research station, and a Jansenist college.

Amersfoort is now a centre for poultry raising and market gardening, and since World War II there has been rapid development of light industry, chiefly the manufacture of metals and chemicals. Johan van Oldenbarnevelt, the Dutch statesman, was born in the town in 1547. Pop. (1999 est.) 123,367.

Amersham, town ("parish"), Chiltern district, county of Buckinghamshire, England, in the Misbourn River valley. The wide High Street of the old town is flanked by half-timbered coaching inns, Georgian houses, and a 17th-century town hall. The parish church of St. Mary dates from the 14th century. Amersham lies on a main rail line from London (26 miles [42 km] southeast) and has attracted commuters. Pop. (1991) 21,711.

Amery, L.S., in full LEOPOLD CHARLES MAURICE STENNETT AMERY (b. Nov. 22, 1873, Gorakhpur, India—d. Sept. 16, 1955, London, Eng.), British politician who was a persistent advocate of imperial preference and tariff reform and did much for colonial territories. He is also remembered for his part in bringing about the fall of the government of Neville Chamberlain in 1940.

Amery was educated at Harrow and at Balliol College, Oxford. In 1899–1900 he was chief correspondent for *The Times* from the South African War and remained on the staff of that paper until 1909, editing *The Times History of the South African War*, 7 vol. (1900–09). He entered Parliament in 1911. He became undersecretary of state for the colonies in 1919 and was moved to a junior post at the Admiralty in 1921.

Amery was made a privy councillor in 1922; and thereafter, apart from a term as first lord of the Admiralty (1922–24), he spent the rest of his career as a minister in imperial departments. In 1925 he created the Dominions Office, which later became the Commonwealth Relations Office. He was excluded from office by the national government (1931–40) and was a sharp critic of the Munich Agreement with Adolf Hitler and Benito Mussolini. In 1940 Amery's voice was influential in breaking the Chamberlain government, to which he applied Oliver Cromwell's injunction to the Long Parliament: "In the name of God, go!" From 1940 to 1945 he was secretary of state for India and Burma (Myanmar).

Amery Ice Shelf, large body of floating ice, in an indentation in the Indian Ocean coastline of Antarctica, west of the American Highland. Though its exact dimensions are unknown, it extends inland from Prydz and MacKenzie bays more than 200 miles (320 km) to the foot of Lambert Glacier. The region in which the ice shelf is located was claimed by Australia in 1933.

Ames, city, Story county, central Iowa, U.S. It lies along the Skunk River, 30 miles (48 km) north of Des Moines. It was laid out in 1865 near the right-of-way of the Cedar Rapids and Missouri Railroad (now part of the Union Pacific system) and was named for Oakes Ames, a railroad financier and Massachusetts congressman. It became the seat of Iowa State

University of Science and Technology, which was established in 1858 and formally opened in 1868. The university's College of Veterinary Medicine (1879) is the oldest in the United States. The National Animal Disease Center (1961), the Ames Laboratory (1942), and other federal and state institutions are in the city. There is some light industry. Inc. town, 1870; city, 1893. Pop. (2000) 50,731.

Ames, Fisher (b. April 9, 1758, Dedham, Mass. [U.S.]—d. July 4, 1808, Dedham), American essayist and Federalist politician of the 1790s who was an archopponent of Jeffersonian democracy.

After graduating from Harvard College in 1774, Ames taught school for five years before turning to law, and in 1781 he was admitted to the bar. Supporting the drive for a new, more powerful federal government, Ames became known for his uncompromising advocacy of the rights of property and his protective attitude toward commercial interests, which he argued for in trenchant writing and commanding speech. He argued for ratification of the U.S. Constitution at the Massachusetts convention, and in 1788 he defeated Samuel Adams for a seat in the first session of the U.S. House of Representatives. Ames was reelected in 1790, 1792, and 1794.

Certain that the country could survive only with a strong central government, Ames supported the financial measures of Secretary of the Treasury Alexander Hamilton. He argued against retaliation for British violations of American rights during 1793 and 1794 when American vessels were seized and American sailors impressed into British service. He gave the greatest speech of his life in favour of the Jay Treaty (1794), which preserved peace with Great Britain, when he swayed the House to pass an enabling appropriation.

Ames declined to run for reelection in 1796 and returned to Dedham the following year. Citing failing health, he refused the presidency of Harvard College. He wanted war with France (1797–98), to cleanse the United States of "Jacobinism," and he approved the Sedition Act of 1798. Following Thomas Jefferson's election as president in 1800, Ames was sure that the republic would sink into anarchy and mob rule. He urged Federalists to gain control of state governments, and—in the years just prior to his death—he became a leader in creating a New England sectional consciousness.

Ames, Leslie, in full LESLIE ETHELBERG GEORGE AMES (b. Dec. 3, 1905, Elham, Kent, Eng.—d. Feb. 26, 1990, Canterbury, Kent), one of the outstanding all-round English cricketers.

At the age of 17 Ames became a batsman for Kent; he became a wicketkeeper in 1927. He began playing in test matches in 1929, and in 1931–38 he was the first-choice keeper for England. His finest season was in 1933, during which he scored 3,059 runs (average 58.80). During World War II he served in the Royal Air Force; subsequently he seldom kept wicket. After his retirement in 1951 he continued with Kent as coach, then as secretary-manager (1960–74). He also was an England test selector in 1950–56 and 1958, and he managed England on tour three times.

In a playing career that spanned 1926–51, the quick, aggressive Ames, as a batsman, scored 37,248 runs (average 43.51) and 102 centuries, including 2,434 runs (average 40.56) and eight centuries in test matches. As a wicketkeeper he dismissed 1,121 batsmen (including 418 stumped, a world record in his lifetime, and 703 caught); he recorded seasonal doubles (at least 1,000 runs and 100 dismissals) in 1928, 1929, and 1932.

Ames, Oakes (b. Jan. 10, 1804, Easton, Mass., U.S.—d. May 8, 1873, Easton), leading figure in the *Crédit Mobilier* scandal following the U.S. Civil War.

Ames left school at age 16 to enter his father's shovel company, Oliver Ames & Sons. Assuming progressively more responsible positions in the firm, he eventually took over management of the company (along with his brother Oliver [1807–77]) upon his father's retirement in 1844.

The gold rushes in California and Australia, along with agricultural development of the Mississippi Valley, created enormous demand for Ames's shovels. By the outbreak of the Civil War, the business was worth \$4,000,000. Drawn to the Republican Party by his ardent beliefs in free soil and free enterprise, Ames ran for a Massachusetts congressional seat in 1862. He won—and then won reelection four times. He was, however, an inconspicuous member of the House.

In 1865, along with brother Oliver and railroad executive T.C. Durant, Ames helped create the *Crédit Mobilier of America*—a company formed to build the Union Pacific Railroad. The *Crédit Mobilier* allowed a small number of individuals to reap vast fortunes from the construction of the line. By early 1868, Congress seemed certain to investigate charges of improper use of government grants to the railroad. But Ames, through shrewd sale of *Crédit Mobilier* stock at bargain prices to appropriate members of Congress, induced his colleagues to abandon the investigation.

A quarrel between Ames and a *Crédit Mobilier* investor led, in 1872, to the publication of documents detailing Ames's misuse of company stock to derail the congressional investigation of 1868. An immediate congressional investigation ensued, concluding with a vote of 182–36 in favour of censuring Ames. He returned to Easton in 1873, a disgraced and broken figure.

Ames, William (b. 1576, Ipswich, Suffolk, Eng.—d. Nov. 14, 1633, Rotterdam), English Puritan theologian remembered for his writings on ethics and for debating and writing in favour of strict Calvinism in opposition to Arminianism.

As a student at Cambridge, Ames viewed cardplaying as an offense to Christian living—no less serious than profanity. In 1609 his dispute with the Church of England's customs of conduct came to a head in his sermon attacking what he saw as the debauchery attending the feast of St. Thomas. Obligated to leave England, he sailed in 1610 to Rotterdam. There, in the fisherman's habit donned for the passage, he debated Nicolaas Grevinckhoven (Grevinckhovius), minister to the local Arminian Church, on the doctrines of atonement and predestination. The Calvinists emphasized that salvation is limited to those who are foreordained by God to receive it and are not capable of falling out of his grace. The Arminians, on the other hand, believed that all men are capable of receiving God's grace if they are believers and if they fulfill certain other conditions.

Ames, considered triumphant in the debates, became widely known throughout the Low Countries. Subsequently, he entered into written disputes with Grevinckhoven on universal redemption and related questions. He served as an observer at the Synod of Dort (1618–19), at which Arminianism was firmly denounced, and as professor of theology at Franeker, in Friesland (1622–33). Among his more important works are *Medulla Theologiae* (1623; *The Marrow of Sacred Divinity*, 1642) and *De Conscientia et Ejus Jure vel Casibus* (1632; *Conscience*, 1639). The latter text was considered for many years by the Dutch Reformed

Church to be a standard treatise on Christian ethics and the variety of ethical situations faced by believers.

Ames, Winthrop (b. Nov. 25, 1870, North Easton, Mass., U.S.—d. Nov. 3, 1937, Boston), theatrical producer, manager, director, and occasional playwright known for some of the finest productions of plays in the United States during the first three decades of the 20th century.

Though his interests lay in the theatre, to please his family Ames entered the publishing business for a few years after completing his education in 1896. He travelled to Europe in 1904, however, to study the management of 60 opera and theatrical companies and returned to Boston to manage the Castle Square Theatre with Loren F. Deland. He became known for his experiments with the stock company there, though they were not a financial success.

In 1908 he became managing director of the New Theatre, largest in New York and intended to house a repertory company producing the very finest in drama, free from commercial pressures. Opening on Nov. 6, 1909, with *Antony and Cleopatra*, Ames went on to produce *The Blue Bird* by Maurice Maeterlinck, John Galsworthy's *Strife*, and others—*Twelfth Night*, *The Winter's Tale*, and *The School for Scandal*—over a two-year period. The plays received much praise, but costs of production were too high and the theatre closed.

Ames then bought the Little Theatre in New York and the Booth Theatre. Productions in the two theatres, which he managed into the 1930s, included *The Philanderer* (1913), by George Bernard Shaw, Galsworthy's *Old English* (1924), George S. Kaufman and Marc Connelly's *Beggar on Horseback* (1924), an extremely successful series of Gilbert and Sullivan revivals at the Booth (1926–29), and *Snow White and the Seven Dwarfs* (1913), the first play designed especially for children and which Ames himself wrote under a pseudonym. Ames also directed the plays he produced. He retired in 1932 because of ill health.

Amesbury, parish, Salisbury district, county of Wiltshire, England, in the valley of the River Avon. It is rich in prehistoric remains, including Stonehenge, 1.5 mi (2.5 km) west, the greatest surviving megalithic structure in the British Isles. At Amesbury (Ambresbyrig, or Ambresbery) a Witan, or Witenagemot, the Anglo-Saxon kings' council of wise men, was held in 932. Now a small market town, Amesbury also caters to the needs of tourists visiting Stonehenge and serves such neighbouring army camps as Larkhill. Pop. (1991) 6,333.

Amesbury, urban town (township), Essex county, northeastern corner of Massachusetts, U.S., on the Merrimack River, at the New Hampshire border. Settled in 1642 as part of Salisbury, it was named for Amesbury, Eng., became a separate precinct in 1654, and was incorporated as a township in 1666. In 1693 the town was a focus of witchcraft hysteria. Amesbury thrived as a shipbuilding port and was an early manufacturing centre (iron, nails, hats, carriages). Textile production flourished after 1812 but declined in the 1920s. The town's economy is now based on light manufacturing. John Greenleaf Whittier lived in Amesbury from 1836 to 1876, and many of his poems describe the surrounding country and life of the community; his house is preserved and his grave is in Union Cemetery. Pop. (2000) 16,450.

amesha spenta (Avestan: "beneficent immortal"), Pahlavi AMSHASPEND, in Zoroastrianism, any of the six divine beings or archangels created by Ahura Mazda, the Wise Lord, to help govern creation. Three are male, three female. Ministers of his power against the

evil spirit, Ahriman, they are depicted clustered about Ahura Mazda on golden thrones attended by angels. They are the everlasting bestowers of good. They are worshipped separately and are said to descend to service on paths of light. Each has a special month, festival, and flower and presides over an element in the world order. In later Zoroastrianism each is opposed by a specific archfiend.

Of the six, Asha Vahishta and Vohu Manah are by far the most important. Asha Vahishta (Avestan: Excellent Order, or Truth) is the lawful order of the cosmos according to which all things happen. He presides over fire, sacred to the Zoroastrians as the inner nature of reality. To the devotee he holds out the path of justice and spiritual knowledge. Vohu Manah (Avestan: Good Mind) is the spirit of divine wisdom, illumination, and love. He guided Zoroaster's soul before the throne of heaven. He welcomes the souls of the blessed in paradise. Believers are enjoined to "bring down Vohu Manah in your lives on Earth" through profound love in marriage and toward one's fellowman. He presides over domestic animals. Khshathra Vairya (Desirable Dominion), who presides over metal, is the power of Ahura Mazda's kingdom. The believer can realize this power in action guided by Excellent Order and Good Mind. Spenta Armaiti (Beneficent Devotion), the spirit of devotion and faith, guides and protects the believer. She presides over Earth. Haurvatāt (Wholeness or Perfection) and Ameretāt (Immortality) are often mentioned together as sisters. They preside over water and plants and may come to the believer as a reward for participation in the natures of the other *amesha spentas*.

amethyst, a transparent, coarse-grained variety of the silica mineral quartz (*q.v.*) that is valued as a semiprecious gem for its violet colour. It contains more iron oxide (Fe₂O₃) than any other variety of quartz, and experts

White-tipped amethyst from Guerrero, Mexico
Lee Boltin

believe that its colour arises from its iron content. Other theories attribute the colour to contained manganese or hydrocarbons. Heating removes the colour from amethyst or changes it to the yellow of citrine; most commercial citrine is made in this manner. Notable occurrences include Brazil, Uruguay, Ontario, and North Carolina.

The name, derived from the Greek *amethystos*, "not intoxicated," expresses the ancient folk belief that the stone protects its owner against drunkenness. In ancient writings the Latin name *amethystus* was used for amethyst, purple corundum, and purple garnet. Amethyst, the birthstone for February, is usually faceted with step cuts or emerald cuts, but has been used for carved intaglios since ancient times. Amethyst is mentioned in the Bible (Ex. 28:19; 39:12) as one of the 12

stones adorning the breastplate (*hoshen*) of the high priests of Yahweh. Its physical properties are those of quartz.

Ameura, genus of trilobites (extinct arthropods) found as fossils in North America rocks dating from the Late Carboniferous to the Late Permian Period (from 320 to 245 million years ago). *Ameura* is characterized by a well-developed cephalon (head) and a long pygidium (tail region) that includes many segments of the central axial lobe. Fossil specimens of these trilobites are frequently found rolled up in a defensive position, as if the animals were attempting to shield their vulnerable undersides.

Amhara, people of the Ethiopian central highlands. The Amhara are one of the two largest ethnolinguistic groups in Ethiopia (the other group being the Oromo). They constitute almost one-third of the country's population. The Amharic language is an Afro-Asiatic language belonging to the Southwest Semitic group. It is related to Ge'ez, the sacred literary language of the Ethiopian Orthodox church, an ancient religion preserved virtually intact from the Monophysite Christianity of the Byzantine church of the 5th century. The Amhara, along with the Tigray peoples, are the principal adherents of this church.

The Amhara long managed to dominate the history of their country; Amharic was the official language of Ethiopia until the 1990s, and it remains important. As descendants of a southward movement of ancient Semitic conquerors who mingled with indigenous Cushitic peoples, they inhabit much of the central and western parts of present-day Ethiopia. All except one of the country's emperors from 1270 to 1974 were Amhara; this dominance created

Selling cotton at the Amhara market in Lalibela, Ethiopia

Victor Englebert

competitive quarrels between the Amhara and their northern neighbours, the Tigray, and other Ethiopian ethnic groups, such as the Oromo. Tensions rose between the Amhara and the Oromo during the period of Marxist rule (1974–91), as the Oromo claimed an increasingly prominent role in the nation's social and political affairs. After 1991 a measure of Amhara sentiment was directed against the Tigray, who had gained influence during the struggle against the Marxists.

The Amhara are primarily agriculturists, producing corn (maize), wheat, barley, sorghum, and teff, a cereal grass (*Eragrostis abyssinica*) that is grown for its grain and is a staple of the region. Traditionally, Amhara social structure was dominated by strong personalized ties between patrons and clients, superiors and inferiors. Generally, a man's importance was in direct proportion to the amount of land he owned. A man of wealth who owned no land, such as a merchant, had little influence. Under the imperial system, land was granted to titled nobles in return for military service to the emperor. The land was farmed by tenant clients. Even in family life all privilege and authority devolved from the patriarch.

Descent is reckoned patrilineally, and married couples usually reside near the husband's home. The Amhara practice three types of marriage: *kal kidan*, *qurban*, and *damoz*. *Kal kidan* (also called *serat*, or *semanyä* ["eighty"]) is marriage by civil contract. It is by far the most common form, though a great percentage of such unions end in divorce. *Qurban* marriages are performed in church and are regarded as sacred; they cannot be dissolved, even after the death of one partner, except in extraordinary circumstances. Because of these restrictions, it is the least common form of marital union. First marriages of the *kal kidan* or *qurban* types are normally arranged by the parents. The third type of marriage—that with the lowest status—is *damoz*, an arrangement by which the woman is paid to be a temporary wife, most often for a period of one or two months. While the woman in a *damoz* relationship receives no claim to the estate of her transient husband, children born under such unions are considered legitimate. *Damoz* unions were outlawed from the mid-20th century, but they continued in practice.

Amharic language, also called AMARINYA, AMHARINYA, or KUCHUMBA, one of the two main languages of Ethiopia (along with the Oromo language). It is spoken principally in the central highlands of the country. Amharic is an Afro-Asiatic language of the Southwest Semitic group and is related to Ge'ez, or Ethiopic, the liturgical language of the Ethiopian Orthodox church; it also has affinities with Tigré, Tigrinya, and the South Arabic dialects.

Although the oldest extant records in Amharic are songs and poems dating from the 14th century, significant literature in any quantity did not begin until the 19th century.

Amharic is written in a slightly modified form of the alphabet used for writing the Ge'ez language. There are 33 basic characters, each of which has seven forms depending on which vowel is to be pronounced in the syllable. The language has been strongly influenced by the Cushitic languages, especially Oromo. The dialects of Amharic are not strongly differentiated from one another. Nearly one-third of the population of Ethiopia spoke Amharic in the late 20th century.

Amherst, town, seat of Cumberland county, northern Nova Scotia, Canada. It is situated near the Cumberland Basin, an arm of Chignecto Bay, and lies just south of the New Brunswick border and Fort Beauséjour National Historic Park, 38 miles (61 km) southeast of Moncton, N.B. Standing on rising ground above the Tantramar Marshes, it was once a village site for Micmac Indians. The

town was called La Planche by 17th-century Acadian settlers, but after its repopulation by New England colonists it was renamed (1759) to honour Jeffrey (later Baron) Amherst, who captured Louisbourg on Cape Breton Island from the French in 1758. Historic structures include the ruined Fort Lawrence, built by the British in 1750, and the town's first Presbyterian church (1788). The Cumberland County Museum is housed in Grove Cottage (1831). Near the town are the Amherst Point Migratory Bird Sanctuary and an experimental farm of the Canadian government. Amherst is a service centre for the surrounding timber, farming, and coal-mining region. Inc. 1889. Pop. (1991) 9,742.

Amherst, town (township), Hampshire county, west-central Massachusetts, U.S. It lies in the Connecticut River valley just northeast of Northampton. Settled as part of Hadley in the 1730s, it was recognized in 1759 as a separate district and named for Jeffrey (later Baron) Amherst, British commander in North America in the French and Indian War. Amherst was incorporated as a town in 1776 and has developed principally as an educational centre.

Noah Webster lived in the town (1812–22) while working on his dictionary and was one of the founders of Amherst College, which was established in 1821. The college's facilities now include the Robert Frost Library, the Mead Art Museum, the Kirby Theatre, and the Pratt Geology Museum. The University of Massachusetts (1947) was founded at Amherst in 1863 as an agricultural land-grant college; its central campus covers 1,100 acres (445 hectares) and contains more than 160 buildings. Hampshire College, which lies south of the town, opened in 1970. The county's academic community also includes the prominent women's institutions of Smith College (1875) and Mount Holyoke College (1837), both within 10 miles (16 km) of Amherst.

A number of homes of literary interest are in the town, including those of the poet Emily Dickinson (born in Amherst, 1830), the poet-novelist Helen Hunt Jackson, and the poet Robert Frost. Pop. (1994 est.) 35,480.

Amherst (Myanmar [Burma]): see Kyaik-kami.

Amherst, Jeffrey Amherst, 1st Baron, also called (1761–87) SIR JEFFREY AMHERST (b. Jan. 29, 1717, Sevenoaks, Kent, Eng.—d. Aug. 3, 1797, Sevenoaks), army commander who captured Canada for Great Britain (1758–60) during the French and Indian War. Amherst, Mass., and several other American towns are named for him.

Amherst received a commission in the foot guards in 1731 and was selected as aide-de-camp first by Lord Ligonier and then by the duke of Cumberland. William Pitt and Ligonier selected him for the Canadian command in 1758. With a force of 14,000 men, he besieged and captured Louisbourg (on Cape Breton Island) and was promoted to chief command in America. He then drew up a plan for a concentric advance on Montreal by three columns, one moving westward up the St. Lawrence River and capturing Quebec, the second northward from Albany by Ticonderoga and Crown Point, and the third westward from Fort Niagara. The first column, under the command of James Wolfe, captured Quebec late in 1759, and the final offensive was launched in 1760, when Montreal surrendered and Canada passed into British hands.

Amherst remained in Canada as governor-general until 1763, quelling the Indian rising under Pontiac in 1761. He acted as commander in chief of the British army almost continuously from 1772 to 1795, but, though

he suppressed the Gordon riots in 1780, his tenure of office was not a successful one, being marred by failure in the war with the Amer-

ican colonies and by the growth of serious abuses in the army.

He was created a baron in 1776 and a field marshal in 1796.

Amherst (of Arracan), William Pitt Amherst, 1st Earl, VISCOUNT HOLMESDALE, BARON AMHERST OF MONTREAL (b. Jan. 14, 1773, Bath, Somerset, Eng.—d. March 13, 1857, Knole, Kent), diplomat who, as British governor-general of India (1823–28), played a central role in the acquisition of Asian territory for the British Empire after the First Burmese War (1824–26).

Amherst inherited in 1797 the baronial title of his uncle Jeffrey Amherst. After serving as British envoy at the court of Naples (1809–11), he was sent to China (1816) to negotiate commercial matters. At the imperial court, however, Amherst declined to perform the kowtow (to strike his forehead on the ground nine times in obeisance), and his mission failed.

Earl Amherst, detail of an oil painting after A. Devis; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery, London

In India he was confronted by a demand from the ruler of Bengal to surrender the whole of eastern Bengal. That demand precipitated the First Burmese War, which Amherst brought to a conclusion with the annexation (1826) of the jungle coastal strips of Arakan and Tenasserim (both in modern Myanmar [Burma]) and Assam (a state of modern India). He was created earl in 1826.

Amherst College, private, independent liberal-arts college for men and women in Amherst, Mass., established in 1821 and chartered in 1825. Noah Webster was one of the founders of the college, which was originally intended to train indigent men for the ministry. It offers flexible programs of study in which students complete two years of courses in the humanities, social sciences, and natural sciences, after which they take seminars and spend their fourth year doing independent re-

search. Originally a men's college, Amherst admitted women as transfer students in 1975 and as first-year students beginning in 1976.

Amhurst, Nicholas (b. Oct. 16, 1697, Marden, Kent, Eng.—d. April 12, 1742, Twickenham, Middlesex), satirical poet, political pamphleteer on behalf of the Whigs, and editor of *The Craftsman*, a political journal of unprecedented popularity that was hostile to the Whig government of Sir Robert Walpole.

Expelled from the University of Oxford in 1719 (probably because of his outspoken views and his satirizing the university in verse), Amhurst settled in London and began a series of satirical papers, *Terrae Filius* ("Son of the Land"). *The Craftsman*, founded in 1726, published articles by Tories as well as by Whigs. In 1737 Amhurst published in it a letter purporting to come from Colley Cibber, then poet laureate, attacking the new (censorship) act for licensing plays; for this "suspected libel," Amhurst and the printer of the journal were imprisoned. After release he was forgotten and passed the rest of his life in obscurity and poverty.

Ami, most numerous indigenous ethnic group on the island of Taiwan, numbering more than 124,000 in the late 20th century and located in the fertile but relatively inaccessible southeastern hilly region and along the eastern coastal plain. Of Malay stock, they speak three dialects of an Indonesian-related language, also called Ami. The Ami traditionally practice slash-and-burn agriculture, growing dry rice, millet, sweet potatoes, tobacco, and betel nut. Today, wet rice cultivation is also important. Composed of extended family units, Ami society revolves around villages (each headed by a chief) containing up to 1,000 people. Men and women have equal rights and responsibilities, but clan organization is actually matrilineal; women own property, and the eldest daughter receives the family inheritance. Daily life is closely bound to religious beliefs; each family group has a hereditary priestess and a

shaman, who practices dream divination. The Ami honour both ancestral and divine spirits; their most important ceremony is held annually after the millet harvest. The Ami have undergone pronounced acculturation, primarily through trading contacts with the Chinese.

amice (derived from Latin *amictus*, "wrapped around"), liturgical vestment worn under the alb. It is a rectangular piece of white linen held around the neck and shoulders by two bands tied at the waist. Probably derived from a scarf worn by the secular classes, it first appeared as a liturgical garment in the Frankish kingdom in the 9th century and was worn by all clergy as a liturgical garment by the 12th century.

The medieval amice was worn as a hood to cover the head and ears. The hood form is retained by some monks.

The Eastern church has no comparable vestment.

Amici, Giovanni Battista (b. March 25, 1786, Modena, Duchy of Modena [Italy]—d. April 10, 1863, Florence), astronomer and optician who made important improvements in the mirrors of reflecting telescopes and also developed prisms for use in refracting spectroscopes (instruments used to separate light into its spectral components).

Amici served as professor of mathematics at the University of Modena from 1815 to 1825 and then became astronomer to the Grand Duke of Tuscany and director of the observatory at the Royal Museum in Florence, where he also lectured at the museum of natural history. He made major advancements in compound-microscope design and introduced (1840) the oil-immersion technique, in which the objective lens is immersed in a drop of oil placed atop the specimen under observation in order to minimize light aberrations.

His name is most often associated with improvements in the microscope and reflecting telescope, but he also put his instruments to good use. His observations of Jupiter's satellites and certain double stars were highly esteemed. Using an improved micrometer of his own design, he made accurate measurements of the polar and equatorial diameters of the Sun. With his improved compound microscope he made discoveries about the circulation of sap in plants and the processes of plant reproduction.

Amicis, Edmondo De: see De Amicis, Edmondo.

amicus curiae (Latin: "friend of the court"), one who assists the court by furnishing information or advice regarding questions of law or fact. He is not a party to a lawsuit and thus differs from an intervenor, who has a direct interest in the outcome of the lawsuit and is therefore permitted to participate as a party to the suit.

An amicus curiae normally may not participate except by leave of the court, and most courts seldom permit persons to appear in such a capacity. The Supreme Court of the United States, however, permits federal, state, and local governments to submit their views in any case that concerns them without obtaining the consent of either the court or the parties. Private persons may appear as amici curiae in the Supreme Court, either if both parties consent or if the court grants permission.

Amida (in Buddhism): see Amitābha.

Amida (Turkey): see Diyarbakır.

amidah, plural AMIDOTH, or AMIDOT, Hebrew 'AMIDA ("standing"), in Judaism, the main section of morning, afternoon, and evening prayers, recited while standing up. On weekdays the amidah consists of 19 benedictions. These include 3 paragraphs of praise, 13 of petition, and another 3 of thanksgiving. Some

call this section of the daily prayer by the ancient name, *shemone 'esre* (Hebrew: "eighteen"), although the 19th benediction was added around 100 CE.

On sabbaths, festivals, and New Moon services, the amidah consists of the first 3 praises and the last 3 thanksgivings, but a special paragraph for the appropriate day replaces the usual 13 benedictions in the middle. Thus the amidah at these services has only 7 sections and is known as *bircath sheva*. The 13 petitions are omitted because it is forbidden to speak of need and sadness at these joyous services.

During the worship service, the amidah is first recited by each individual as a silent prayer, giving any sinner a chance to atone without embarrassment. The prayer is then repeated aloud by the reader. There is never a Jewish service without an amidah.

amide, any member of either of two classes of nitrogen-containing compounds related to ammonia and amines. The covalent amides are neutral or very weakly acidic substances formed by replacement of the hydroxyl group (OH) of an acid by an amino group (NR₂, in which R may represent a hydrogen atom or an organic combining group such as methyl, CH₃). The carboxamides (R'CONR₂), which are derived from carboxylic acids (R'COOH), are the most important group. Sulfonamides (RSO₂NR₂) are similarly related to the sulfonic acids (RSO₃H).

Ionic, or saltlike, amides are strongly alkaline compounds ordinarily made by treating ammonia, an amine, or a covalent amide with a reactive metal such as sodium.

Covalent amides derived from ammonia are solids, except formamide, which is liquid; those containing fewer than five carbon atoms are soluble in water. They are nonconductors of electricity and solvents for both organic and inorganic substances. Covalent amides, even those of low molecular weight, have high boiling points.

There are no practical natural sources of simple covalent amides, although polyamides (amides linked together to form large molecules called polymers) occur in great abundance as the protein of living systems. Simple amides ordinarily are prepared by reaction of acids or acid halides with ammonia or amines. They can also be produced by the reaction of water with nitriles.

The characteristic reaction of covalent amides is hydrolysis (a chemical reaction with water), by which they are converted to acids and amines; this reaction ordinarily is slow unless it is catalyzed by a strong acid, an alkali, or an enzyme. Amides also can be dehydrated to nitriles. Amides are not readily oxidized nor reduced, although hydrogenation (addition of hydrogen at high temperatures and pressures) in the presence of a catalyst will convert most amides of carboxylic acids to amines. The powerful reducing agent lithium aluminum hydride transforms amides into amines. Reaction of amides with acid chlorides or anhydrides produces imides, which are compounds with two carbonyl (CO) groups attached to the same nitrogen atom.

Among the amides of commercial importance are acetamide, also called ethanamide (CH₃CONH₂) and dimethylformamide HCON(CH₃)₂, which are used as solvents, the sulfa drugs, and the nylons. Urea or carbamide [CO(NH₂)₂] is a crystalline compound that is formed as the end product of the metabolism of protein and excreted in the urine of mammals. It is synthesized in large quantities from ammonia and carbon dioxide for use in fertilizers, in animal feed, and in manufacturing a class of polymers known as urea-formaldehyde resins, used in making plastics.

Amidism, sect of Mahāyāna Buddhism centring on worship of Amida (in Japanese; Sanskrit Amitābha; Chinese O-mi-t'ō-fo), Buddha

(Buddha of Infinite Light), whose merits can be transferred to a believer. Amidism holds that the faithful—by believing in Amida, hearing or saying his name, or desiring to share in his Western Paradise—can be reborn in the Pure Land (see Pure Land Buddhism). Originating in India, Amidism emerged in China in the 4th century and by the 9th century was brought to Japan, where, in the 20th century, the Pure Land sects compose one of the two largest Buddhist groups. See also Amitābha.

Amiel, Henri Frédéric (b. Sept. 27, 1821, Geneva, Switz.—d. May 11, 1881, Geneva), Swiss writer known for his *Journal intime*,

Amiel, detail of a heliograph by an unknown artist

J.P. Ziolo

a masterpiece of self-analysis. Despite apparent success (as professor of aesthetics, then of philosophy, at Geneva), he felt himself a failure. Driven in on himself, he lived in his *Journal*, kept from 1847 until his death and first published in part as *Fragments d'un journal intime* (1883–84; later enlarged editions; definitive ed. by L. Bopp, 1939–48). It reveals a sensitive man of great intellectual ability, struggling for values against the skepticism of the age. Widely translated, it gained Amiel lasting fame.

Amiens, city, capital of Somme département, Picardie région, principal city and ancient capital of Picardy, northern France, in the Somme River valley, north of Paris. Famed since the European Middle Ages are its textile industry and its great Gothic Cathedral of Notre-Dame, one of the finest in France. Known as Samarobriua in pre-Roman times and capital of the Ambiani (whence the modern name), Amiens became a Roman city, Christianized in the 4th century by St. Firmin, its first bishop. Its territory became the medieval countship of Amiénois, and its citizens profited from rivalry between bishop and count to gain a charter early in the 12th century. The Peace of Amiens (1802) marked a short pause in the Napoleonic Wars. In 1914, after a brief incursion into the city, the invading Germans dug in 18 miles (29 km) east; their final drive in 1918 was stopped 8 miles (13 km) from the city. In World War II, Amiens was occupied by the Germans. After serious damage in both wars, the city centre was rebuilt.

The old part of Amiens, including the reconstructed 17th-century city hall, the 15th-century Church of Saint-Germain, and the ancient theatre with the Louis XVI facade, is latticed with seven branches of the river.

The cathedral was begun in 1220 on the plans of Robert de Luzarches and was finished about 50 years later (there were subsequent additions). Its galleried and rose-windowed facade, pierced by three portals and topped by twin towers, is splendid. It has a remarkable interior with a soaring nave and bold supporting columns, employing the logic of Romanesque while imposing the open and dramatic qualities of Gothic.

Apart from textiles, there is some manufacturing, including machinery, chemicals, and tires. Truck farmers from the adjacent heavily

watered bottom lands (*hortillons*) hold market in the city from small boats. Longeau, near Amiens, is an important railroad junction. Pop. (1982) 130,302.

Amiens, Treaty of (March 27, 1802), an agreement signed at Amiens, Fr., by Britain, France, Spain, and the Batavian Republic (the Netherlands), achieving a peace in Europe for 14 months during the Napoleonic Wars. It ignored some questions that divided Britain and France, such as the fate of the Belgian provinces, Savoy, and Switzerland and the trade relations between Britain and the French-controlled European continent. Notwithstanding military reverses overseas, France and its allies recovered most of their colonies, though Britain retained Trinidad (taken from Spain) and Ceylon (taken from the Dutch). France recognized the Republic of the Seven Ionian Islands and agreed to evacuate Naples and the Papal States. The British were to restore Egypt (evacuated by the French) to the Ottoman Empire and Malta to the Knights of St. John within three months. The rights and territories of the Ottoman Empire and of Portugal were to be respected, with the exception that France would keep Portuguese Guinea.

'Āmīlī, Bahā' ad-Dīn Muḥammad ibn Ḥusayn, al-, also called SHAYKH BAHĀ'Ī (b. March 20, 1546, Baalbek, Syria—d. Aug. 20, 1622, Iran), theologian, mathematician, jurist, and astronomer who was a major figure in the cultural revival of Ṣafavid Iran.

Al-'Āmīlī was educated by his father, Shaykh Ḥusayn, a Shī'ite theologian, and by excellent teachers of mathematics and medicine. After his family left Syria in 1559 to escape persecution by the Ottoman Turks, al-'Āmīlī lived in Herāt (now in Afghanistan) and Isfahan, Iran. He attached himself to the court of 'Abās I the Great, serving for many years as the *shaykh al-Islām* (chief judge of the Muslim court of law) of Eṣfāhān, and writing during that time a treatise on Shī'ite jurisprudence and its application in Iran (*Jāmi'e Abbāsī*). He made a pilgrimage to Mecca and visited with many scholars, doctors, and mystics on a homeward journey that took him to Iraq, Egypt, the Hejaz, and Palestine.

In his poetry al-'Āmīlī expounded complex mystical doctrines in simple and unadorned verse. His best-known poem, *Nān u-ḥalwā* ("Bread and Sweets"), describes the experiences of an itinerant holy man who may well be al-'Āmīlī himself on the Mecca pilgrimage. *Kashkūl* ("The Beggar's Bowl"), containing both stories and verses, was translated widely. His major work of astronomy is *Tashriḥu'l-aflāk* ("Anatomy of the Heavens").

Al-'Āmīlī was responsible for the revival of mathematical sciences in Iran, the study of which had been neglected for more than 100 years. His *Khulāṣat al-ḥisāb* ("The Essentials of Arithmetic"), written in Arabic, was translated several times into Persian and German. The work was a standard textbook until the beginning of the 20th century.

Amin, (Muhammad) al- (b. April 787—d. Sept. 24/25, 813, Iraq), sixth caliph of the 'Abbāsīd dynasty.

As the son of Hārūn ar-Rashīd, the fifth caliph, and Zubayda, a niece of al-Manṣūr, the second caliph, al-Amin took precedence in the succession over his elder half brother, al-Ma'mūn, whose mother was a Persian slave. In 809, al-Amin succeeded to the caliphate, and al-Ma'mūn was vested with the administration of the eastern Khorāsān region. Relations between the brothers soon broke down, and in 810 al-Amin declared his own son as his direct heir. Open hostilities began in 811, and by 812 al-Amin was besieged in Baghdad, the defense of which lasted more than a year. Al-

Amin was captured and executed, apparently against the wishes of his brother.

Amin, Idi, in full IDI AMIN DADA OUMEE (b. 1924/25, Koboko, Uganda—d. Aug. 16, 2003, Jiddah, Saud.Ar.), military officer and president (1971–79) of Uganda whose regime was noted for its brutality.

A member of the small Kakwa ethnic group of northwestern Uganda, Amin had little education; he joined the King's African Rifles of the British colonial army in 1946 as an assistant cook. He quickly rose through the ranks, serving in the Allied forces' Burma (Myanmar) campaign during World War II and in

Amin
Janet Griffith/Black Star

the British action against the Mau Mau revolt in Kenya (1952–56). Amin was one of the few Ugandan soldiers elevated to officer rank before Ugandan independence in 1962, and he became closely associated with the new nation's prime minister and president, Milton Obote. He was made chief of the army and air force (1966–70). Conflict with Obote arose, and on Jan. 25, 1971, Amin staged a successful coup. He became president and chief of the armed forces in 1971, field marshal in 1975, and life president in 1976.

Amin was noted for his abrupt changes of mood, from buffoonery to shrewdness, from gentleness to tyranny. He was often an extreme nationalist. His expulsion of all Asians from Uganda in 1972 led to the breakdown of the country's economy, and he publicly insulted Great Britain, the United States, and numerous world leaders. A Muslim, he reversed Uganda's amicable relations with Israel and befriended Libya and the Palestinians; in July 1976 he was involved in the Palestinian hijacking of a French airliner to Entebbe (see Entebbe raid). He took tribalism to an extreme by allegedly ordering the persecution of Acholi, Lango, and other ethnic groups. Amin came to be known as the "Butcher of Uganda"; it is believed that some 300,000 people were killed and countless others tortured during his presidency.

In October 1978 Amin ordered an attack on Tanzania. Aided by Ugandan nationalists, Tanzanian troops eventually overpowered the Ugandan army. As the Tanzanian-led forces neared Kampala, Uganda's capital, on April 13, 1979, Amin fled. Escaping to Libya, he finally settled in Saudi Arabia, where he died in 2003.

amine, any member of a family of nitrogen-containing organic compounds that is derived, either in principle or in practice, from ammonia (NH₃).

For full treatment, see MACROPAEDIA: Chemical Compounds.

amino acid, any of a group of organic molecules that consist of a basic amino group (–NH₂), an acidic carboxyl group (–COOH), and an organic R group (or side chain), which is unique to each amino acid. The formula of a general amino acid is

The only exceptions to this basic structure are proline and hydroxyproline, in which the primary amino group is replaced by a secondary amino group present in a cyclic structure.

For full treatment, see MACROPAEDIA: Biochemical Components of Organisms.

Amir Ali, Sayyid (b. April 6, 1849, Cuttack, India—d. Aug. 3, 1928, Sussex, Eng.), jurist, writer, and Muslim leader who favoured British rule in India rather than possible Hindu domination of an independent India.

Amir Ali, who traced his ancestry to Muhammad's daughter Fātimah, took his law degree at the University of Calcutta, was called to the bar (1873) in England, and returned to practice in Calcutta, becoming a judge of the High Court in 1890. A resident of England from 1904, he was appointed to the judicial committee of the Privy Council in 1909.

Amir Ali founded the National Mohammedan Association (1877) to provide Muslims with experience in Western political techniques and to protect their interests, and he helped secure in 1909 the first communal electorates for his people. He founded the British Red Crescent Society, and he furthered Western understanding of Islām by writing the first presentation of Islām by a Muslim in English, *The Critical Examination of the Life and Teachings of Mohammed* (1873). His *Spirit of Islam* (1891) remains a Muslim classic.

Amir Khosrow (b. 1253, Patiali [now in Uttar Pradesh, India]—d. 1325, Delhi), poet and historian, considered one of India's greatest Persian-language poets.

Amir Khosrow was the son of a Turkish officer in the service of Iltutmish, sultan of Delhi, and for his entire life he enjoyed the patronage of the Muslim rulers of Delhi. He became a follower of the saint of Delhi, Muhammad Nizām-ud-Dīn Awliyā, of the Chishtī dervish order; he was buried next to the saint's tomb. Sometimes known as "the parrot of India," Amir Khosrow wrote five *divans*, which were compiled at different periods in his life, and *Khamseh* ("Pentology"), five long idylls in emulation of the *Khamseh* of the Persian poet Nezāmī (c. 1141–1209). Amir Khosrow's pentology deals with themes famous in Islāmic literature. He is also known for a number of prose works, including the *Khazā'in al-futūh* ("The Treasure-Chambers of the Victories"), also called *Tārīkh-e 'Alā'ī* ("The History of Ala"). Two historical poems for which he is known are *Nuh Sipīhr* ("The Nine Heavens") and the *Tughluq-nāmāh* ("The Book of Tughluq").

Amirante Isles, group of coral islands in the western Indian Ocean, about 200 miles (320 km) southwest of the Seychelles group and forming, with the Seychelles and other islands, the Republic of Seychelles. The Amirante Isles were known to Persian Gulf traders centuries ago and were sighted by the navigator Vasco da Gama on his second voyage to India, in 1502, but they are still virtually uninhabited. Individual islands are leased by the Seychelles government to private companies to exploit, usually by harvesting coconut.

Āmirīyah, al-, formerly MARYŪṬ, industrial district of al-Iskandariyah (Alexandria) *muhāfazah* (governorate), northern Egypt. The centre of the 913-sq-mi (2,365-sq-km) district, which adjoins Lake Maryūt (Mareotis) on the southwest, is al-Āmirīyah town. This town was originally a small gypsum-mining centre on the desert roads leading south to Cairo and west along the coast to Marsā Matrūh. Al-Āmirīyah's modern development began in the late 1970s, when construction started on industrial plants in the district.

Amis, Sir Kingsley (b. April 16, 1922, London, Eng.—d. Oct. 22, 1995, London), novelist, poet, critic, and teacher who created in his first novel, *Lucky Jim*, a figure that became a household word in Great Britain in the 1950s.

Amis was educated at the City of London School and at St. John's College, Oxford (B.A., 1949). His education was interrupted during World War II by his service as a lieutenant in the Royal Corps of Signals. From 1949 to 1961 he taught at universities in Wales, England, and the United States.

Amis' first novel, *Lucky Jim* (1954, filmed 1957), was an immediate success and remains his most popular work. Its disgruntled antihero, a young university instructor named Jim Dixon, epitomized a newly important social group that had risen by dint of scholarships from lower-middle-class and working-class backgrounds only to find the more comfortable perches still occupied by the well-born. *Lucky Jim* prompted critics to group Amis with the Angry Young Men, who expressed similar discontent. Amis' next novel, *That Uncertain Feeling* (1955), had a similar antihero. A visit to Portugal resulted in the novel *I Like It Here* (1958), while observations garnered from teaching in the United States were expressed in the novel *One Fat Englishman* (1963).

Amis went on to write more than 40 books, including some 20 novels, many volumes of poetry, and several collections of essays. His apparent lack of sympathy with his characters and his sharply satirical rendering of well-turned dialogue were complemented by his own curmudgeonly public persona. Notable among his later novels were *The Green Man* (1969), *Jake's Thing* (1978), and *The Old Devils* (1986). As a poet, Amis was a representative member of a group sometimes called "The Movement," whose poems began appearing in 1956 in the anthology *New Lines*. Poets belonging to this school wrote understated and disciplined verse that avoided experimentation and grandiose themes. In 1990 Amis was knighted, and his *Memoirs* were published in 1991. His son Martin Amis became a well-known novelist.

Amis, Martin (b. Aug. 25, 1949, Oxford, Oxfordshire, Eng.), English satirist known for his virtuoso storytelling technique and his dark views of 20th-century English society.

As a youth Amis, the son of the celebrated novelist Kingsley Amis (q.v.), thrived literarily on a permissive home atmosphere and a "passionate street life." He graduated from Exeter College, Oxford, in 1971 with first-class honours in English and worked for several years as an editor, on such publications as the *Times Literary Supplement*.

Amis' first novel was *The Rachel Papers* (1973), the tale of a young antihero preoccupied with his health, his sex life, and his efforts to get into Oxford. His other novels include *Other People* (1981), *London Fields* (1989), and *Night Train* (1998). In Amis' works, according to one critic, "morality is nudged toward bankruptcy by 'market forces.'" His short-story collection *Einstein's Monsters* (1987) depicts the stupidity and horror of nuclear weapons.

Amis' autobiography, *Experience* (2000), which often focuses on his father, was acclaimed for an emotional depth and profundity that some had found lacking in his novels.

Amis and Amiles, characters in an Old French metrical romance, based on an older legend of friendship and sacrifice. In its simplest form the story tells of the knights Amis and Amiles and of their devotion to one another.

The tale was introduced to the West by way of Byzantium and found its way into French literature through Latin (hence the characters' names: "Amicus" and "Amelius" in Latin). It became attached to the web of Charlemagne legends in the late 12th-century *chanson de*

geste *Amis et Amiles*, a poem that contains passages of great beauty, and later versions appeared in most European languages. The first English version of the story was *Amis and Amiloun*, composed in the Midlands dialect late in the 13th century.

Amish, also called AMISH MENNONITE, member of a Christian group in North America. The church originated in the late 17th century among the followers of Jakob Ammann.

History and church structure. Jakob Ammann (c. 1644–c. 1730) was a Mennonite leader whose teachings caused a schism. Ammann insisted that any excommunicated Mennonite church member should be shunned and that anyone who lied should be excommunicated. Following Jesus' example, he introduced foot washing into the worship service and taught that church members should dress in a uniform manner, that beards should not be trimmed, and that it was wrong to attend services in a state church. Although Ammann sought reconciliation with the Mennonites, his attempts failed. Amish communities sprang up in Switzerland, Alsace, Germany, Russia, and Holland, but immigration to North America in the 19th and 20th centuries and assimilation with Mennonites eliminated the Amish in Europe.

The Amish began immigrating to North America early in the 18th century; they first settled in eastern Pennsylvania, where a large community remains. Schism occurred after 1850 because of tensions between the "new order" Amish, who accepted social change and technological innovation, and the "old order" Amish, who did not. During the next 50 years, about two-thirds of the Amish formed separate, small churches of their own or joined either the Mennonite Church or the General Conference Mennonite Church.

In the late 20th century there were more than 150,000 Amish living in more than 200 Old Order Amish settlements in the United States and Canada; the largest were in Pennsylvania, Ohio, Indiana, Iowa, Illinois, and Kansas, and others were in Wisconsin, Missouri, and Minnesota. Settlements are divided into church districts, autonomous congregations of about 75 baptized members. If the district becomes much larger, it is again divided, because members meet in each other's homes. There are no church buildings. Each district has a bishop, two to four preachers, and an elder; there are no general conferences, mission groups, or cooperative agencies.

Beliefs and way of life. Humility, family, community, and separation from the world are the mainstays of the Amish. Everyday life and custom are governed by an unwritten code of behaviour called the *Ordnung*, and shunning (*Meidung*) remains an integral way in which the community deals with disobedient members. In religious doctrine the Amish differ little from the Mennonites. Holy Communion is celebrated twice each year, and foot washing is practiced by both groups. Persons are baptized when they are admitted to formal membership in the church at about the age of 17 to 20. Religious services are conducted in High German, and Pennsylvania Dutch—an admixture of High German, various German dialects, and English—is spoken at home and in daily discourse (see Pennsylvania German). Services are held on a rotating basis in family homes and barns. A wagon, filled with benches for the service and dishes and food for the meal that follows, is often pulled to the host's property. In most Amish homes a special place is reserved alongside the Bible for the *Martyr's Mirror*, a book chronicling Amish history and honouring the many Amish, Mennonite, and Anabaptist forebears who died for their faith. *The Budget*, established in 1890, is the national newspaper serving Amish and Mennonite communities; it is published in Sugar Creek, Ohio.

The Amish are known for their clothing, most of it self-made. Men and boys wear broad-brimmed black hats, dark-coloured suits, straight-cut coats without lapels, broad-fall pants, suspenders, solid-coloured shirts, and black socks and shoes. Men grow beards after they marry but are forbidden to have mustaches. Old Order Amish women and girls wear bonnets, long full dresses with capes over the shoulders, shawls, and black shoes and stockings; their capes and aprons are fastened with straight pins or snaps. Amish women never cut their hair, which is worn in a bun, and they are not allowed to wear jewelry. The Amish attire reflects their respect for tradition and their interpretation of biblical strictures against conforming to the ways of the world.

The Old Order Amish shun personal, home-based telephones but will occasionally use a communal one. They also eschew automobiles and ride bicycles and drive horse-and-buggies instead, though many of them will, on occasion and in emergencies, ride in cars, trains, and buses operated by others. Although the buggies are traditional boxlike vehicles, they are not always black; some of them are white, gray, or even yellow, and many Amish and Mennonite groups can be distinguished by the colour of buggy. The buggies may be equipped with such modern conveniences as heaters and windshield wipers. The use of electricity is avoided, as it is a connection to the world that could lead to temptations and worldly amenities detrimental to the community and family life; exceptions to this ban have included the use of electric flashers on buggies in order to drive legally in certain communities and the use of farm equipment that cannot be operated without some electricity and without which the community's economic livelihood would be threatened. Milking equipment, for example, may be impossible to operate without electricity. Bottle gas is often used to operate appliances, and gas-pressured lanterns and lamps might be used for indoor lighting. The New Order Amish permit the use of electricity, the owning of cars, and telephones in the home.

The Amish are excellent farmers, growing and storing the majority of their food and purchasing only staples such as flour and sugar. The Old Order Amish refuse to use most modern farm machinery. What modern machinery they do use is often operated not by electricity but by an alternative power source. The Amish are famous for their barn raisings. These efforts often involve hundreds of men and scores of women who feed the workers. These barns are a reminder of Amish tradition, community, industry, and craft. The hex signs that often adorn the barns—round geometric emblems painted to ward off evil—are synonymous with the communities of the "Pennsylvania Dutch."

The Amish typically accept the photographing of their way of life but forbid photos of themselves, believing such things to be graven images in violation of the Second Commandment. For this reason the dolls young Amish girls play with are traditionally faceless. Musical instruments are forbidden by the Old Order Amish, as playing these, they believe, would be a "worldly" act contrary to the critical *Gelassenheit*: the spirit of humility, modesty, and informality that lies at the heart of the Amish way of life and which the Amish believe was exemplified by Jesus Christ. Other Amish may play an instrument in private, such as the accordion or harmonica, but never in public. Singing is important to Amish life, at home or in church. Selections from the *Ausbund* (their hymnal) are commonly sung. Group singing is always in unison and never harmonized. Hymn singing is popular on Sunday evenings, especially among young Amish, and on these occasions a separate hymnal (with "faster tunes"), called the "thin book," is used.

Amish quilts, meticulously stitched by groups of Amish girls and women, are popular with

tourists and highly prized by collectors. The quilting bees are a form of socialization and relaxation for Amish women, and the group effort reflects the Amish virtues of community. The quilts can be intricate in design and have colourful patterns but may not contain representational images, which are considered fancy and prideful. The selling of quilts, handmade crafts such as hex signs, and baked goods such as friendship bread and shoofly pie is a common source of income for Amish families.

Amish children typically attend one-room schools run by the community, and they attend school only through the eighth grade; this limitation was deemed acceptable in the United States by a 1972 Supreme Court ruling. Instruction is in English and concentrates on the basics of reading, writing, and math. Amish history is also taught, along with practical farming and homemaking skills. As in many of the separatist branches of Protestantism, convincing the children of believers to stay in the faith community can often be a challenge.

The reserved manner that the Amish try to maintain does not prevent them from partaking of common pastimes and games. Volleyball and softball are popular with many Amish families. Once the daily chores are finished and the children's schoolwork completed, Amish families will often read or sing together before going to bed.

The Amish are not involved in state or national politics, and they do not serve in the military. They also disavow social security and most types of insurance, often pooling their resources to help Amish families in need, but they will visit doctors, dentists, and opticians. The Amish are in the world but not really of it, as they try, in their simple and placid ways, to maintain the greatest possible separation from the rest of society.

Amitābha (Sanskrit: "Infinite Light"), Japanese AMIDA, Chinese O-MI-T'O, in Buddhism, the saviour deity worshiped principally by members of the Pure Land sect in Japan. As related in the *Sukhāvati-vyūha-sūtra* (the fundamental scripture of the Pure Land sects), ages ago a monk named Dharmākara made a number of vows, the 18th of which promised that, on his attaining buddhahood, all who believed in him and who called upon his name would be born into his paradise and would reside there in bliss until they had obtained nirvana. Having accomplished his vows, the monk reigned as the buddha Amitābha in the Western Paradise, called Sukhāvati, the Pure Land.

The cult of Amitābha, which emphasizes faith above all else, came to the fore in China about AD 650 and from there spread to Japan,

Great bronze Amida (Daibutsu) at Kamakura, Japan, 1252

where it led in the 12th and 13th centuries to the formation of the Pure Land school and the True Pure Land school, both of which have large followings today.

Amitābha as a saviour figure was never as popular in Tibet and Nepal as he was in East Asia, but he is regarded in those countries as one of the five "self-born" buddhas who have existed eternally. According to this concept he manifested himself as the buddha Gautama and as the bodhisattva ("buddha-to-be") Avalokiteśvara. His colour is red, his posture one of meditation, his symbol the begging bowl, his element water, his direction the west, his sense perception taste, his sense organ the tongue, and his location in the human body the mouth.

As a bestower of longevity, Amitābha is called Amitāyus (Sanskrit: "Infinite Life"). In China and Japan the two names are often used interchangeably, but in Tibet the two forms are never confounded, and Amitāyus is worshiped in a Lamaist ceremony for obtaining long life. See also Pure Land Buddhism.

Amitāyur-dhyāna-sūtra (Sanskrit: "Discourse Concerning Meditation on Amitāyus"), one of three texts basic to Pure Land Buddhism. Together with the larger and smaller *Sukhāvati-vyūha-sūtras* (Sanskrit: "Description of the Western Paradise Sutras"), this text envisions rebirth in the celestial Pure Land of Amitāyus, the Buddha of Infinite Life (virtually identical with Amitābha, "Infinite Light," called Amida in Japan).

This sutra presents 16 forms of meditation as means of reaching the Pure Land and concludes that even the most wicked can attain this paradise by invoking the name of Amitāyus. It contains many references to bodhisattvas, or Buddhas postponing final bliss in order to accomplish the salvation of men.

The *Amitāyur-dhyāna-sūtra* was translated into Chinese under the title *Kuan-wu liang-shou ching* in AD 424 and has inspired many Chinese commentaries. The Japanese version is entitled *Kammuryōju-kyō*. The Sanskrit original has since been lost.

‘Amm (Arabian god): see Ilumquh.

Amman, Arabic ‘AMMĀN, biblical Hebrew RABBAH, or RABBAT BENE ‘AMMON ("Great [or Capital] City of the Sons of Ammon"), ancient Greek PHILADELPHIA, capital of the Hashemite Kingdom of Jordan. The largest city of Jordan, it is the only one with a modern urban infrastructure. Amman is built on rolling hills at the eastern boundary of the ‘Ajlūn Mountains, on the Wadi ‘Ammān and its tributaries.

Its focus of settlement has been the small plateau (modern Mount Al-Qal‘ah) just north of the wadi. Fortified settlements have existed there from the Chalcolithic period (c. 4000–c. 3000 BC). The city became capital of the Ammonites, a Semitic people mentioned in the Bible; the biblical and modern names both trace back to "Ammon." The "royal city" taken by King David's general Joab (II Samuel 12:26) was probably the acropolis atop the plateau. King David sent Uriah the Hittite to his death in battle before the walls of the city so that he might marry his wife Bathsheba (II Samuel 11).

Rabbah declined in later centuries. It was conquered by Egypt's King Ptolemy II Philadelphus (reigned 285–246 BC), and he renamed it Philadelphia after himself; the name was retained through Byzantine and Roman times. Philadelphia was a city of the Decapolis (Greek: "Ten Cities"), a Hellenistic league of the 1st century BC–2nd century AD. It was rebuilt by the Romans.

At the rise of Islām, Amman was taken by the general Yazīd ibn Abī Sufyān in AD 635; by c. 1300 it had disappeared. In 1878 the

Ottoman Turks resettled the site with Circassian refugees from Russia; it remained a small village until after World War I.

After the war Transjordan became part of the Palestine mandate, but the British government, as mandatory, effectively severed it from western Palestine (1921) and established a protected emirate of Transjordan, under the rule of Abdullah, son of Husayn ibn ‘Alī, then king of the Hejaz and sharif of Mecca. Amman became capital of this new state; its modern development began in this period and was accelerated by Jordanian independence (1946). The city grew rapidly; the urban area received a large influx of Palestinian Arab refugees after the Arab-Israeli War of 1948–49. The refugee problem became more serious after the Six-Day War of 1967, when

Dwellings rising behind the Roman amphitheatre, Amman, Jordan
Ara Güler—Istanbul

Jordan lost its territories west of the Jordan River to Israel. Conflict between the Jordanian government and Palestinian guerrillas erupted into open civil war in 1970 in the streets of Amman; although government forces prevailed, the city was severely damaged.

Amman is Jordan's chief commercial, financial, and international trade centre. The royal palaces are to the east; the Parliament is in the western section. The University of Jordan (1962) is at Amman. Chief industries include food and tobacco processing and the manufacture of textiles, paper products, plastics, and aluminum utensils. On the city's outskirts are factories making electrical batteries and cement. Amman is Jordan's chief transportation centre: two highways lead toward Jerusalem, and one of the city's main thoroughfares becomes the road to As-Salt, to the northwest. Jordan's main north-south highway, with its southern terminus at Al-‘Aqabah port, runs through the city. Just east is Amman International Airport, near the tracks of the old Hejaz Railway. Sites of interest include remains of the ancient citadel, the adjoining archaeological museum, and a large finely preserved Roman amphitheatre. Pop. (2000 est.) 1,147,447.

Amman, Jost (b. June 13, 1539, Zürich, Switz.—d. March 17, 1591, Nürnberg, Bavaria [Germany]), painter, printmaker, and skilled book illustrator.

Amman was educated in Zürich and worked for a short time in Basel, where he designed glass paintings for prominent families. About 1560–61 he moved to Nürnberg but retained his citizenship of Zürich until 1577.

His engraving of the poet-dramatist Hans Sachs testifies to his craftsmanship. In drawings, such as "Entry of Maximilian II into Nürnberg in 1570," he revealed himself as a

brilliant and witty recorder of contemporary events. His engravings include historical portraits, such as those of the kings of France; heraldic designs; and scenes of warfare, hunting, and pageantry. He produced woodcuts for various works. The most notable was a book on the arts and crafts with poems by Hans Sachs entitled *Eygentliche Beschreibung aller Stände auff Erden* (1568; "Actual Description of All the Professions in the World").

Ammann, Othmar Herman (b. March 26, 1879, Schaffhausen, Switz.—d. Sept. 22, 1965, Rye, N.Y., U.S.), engineer and designer of numerous long suspension bridges, including the Verrazano-Narrows Bridge over New York harbour, at its completion (1965) the longest single span in the world.

In 1904 Ammann immigrated to the United States, where he helped design railroad bridges. Joining the Pennsylvania Steel Company in 1905, he worked on the Queensboro Bridge, New York City. During his term (1912–23) as chief assistant to the noted bridge engineer Gustav Lindenthal, he helped design and build the Hell Gate (steel arch) Bridge, New York City, and the Ohio River Bridge, Sciotoville, Ohio.

In 1923 Ammann set up his own engineering firm in New York City, and in 1924 the Port of New York Authority agreed to finance his proposed bridge across the Hudson River between New Jersey and upper Manhattan. When finished in 1931, the George Washington Bridge was the longest in the world.

Ammann was chief engineer of the Port of New York Authority from 1930 to 1937 and director of engineering from 1937 to 1939. As chief engineer, he was in charge of building the Bayonne Bridge over the Kill van Kull, N.J., the Outerbridge Crossing and Goethals Bridge across Arthur Kill, and the Lincoln Tunnel under the Hudson River. As director of engineering, he directed the building of the Bronx-Whitestone Bridge and the Triborough Bridge, New York City. He sat on the Board of Engineers in charge of San Francisco's Golden Gate Bridge, which opened in 1937.

In 1939 Ammann returned to private practice, designing bridges and highways in New Jersey and New York. He served on the board that investigated the Tacoma Narrows Bridge aerodynamic failure in 1941. In partnership with Charles S. Whitney from 1946, Ammann designed the Throgs Neck Bridge, New York City, the Dulles International Airport, outside Washington, D.C., and three buildings for New York City's Lincoln Center for the Performing Arts.

Ammannati, Bartolommeo (b. June 18, 1511, Settignano, near Florence [Italy]—d. April 22, 1592, Florence), Italian sculptor and architect whose buildings mark the transition from the Renaissance to the Baroque style.

Ammannati began his career carving statues in various Italian cities in the 1530s and '40s. He trained first under Baccio Bandinelli and then under Jacopo Sansovino in Venice, working with the latter on the Library of St. Mark.

He was called to Rome in 1550 by Pope Julius III on the advice of the architect and art historian Giorgio Vasari. Ammannati's most important work there was in collaboration with Vasari and Giacomo da Vignola on the villa of Pope Julius, the Villa Giulia (begun 1551). Cosimo de' Medici (Cosimo I) brought Ammannati back to Florence in 1555; he was to spend almost all of his remaining career in service to the Medicis. His first commission was to finish the Laurentian Library, begun by Michelangelo. Ammannati interpreted a clay model sent him by Michelangelo in 1558 to produce the impressive staircase, leading from the vestibule into the library proper.

Ammannati's masterpiece in Florence is the Pitti Palace, where, beginning in 1560, he enlarged the basic structure by Filippo Brunelleschi, designing a courtyard and facade

"Doris," detail from the "Fountain of Neptune," executed from Bartolommeo Ammannati's model by Andrea Calamech, 1563-75; in Piazza della Signoria, Florence

Alinari—Art Resource/EB Inc

opening onto the Boboli Gardens, which Ammannati had a part in designing. The facade overlooking the courtyard is very unusual in its rusticated (rough-hewn) treatment of successive levels of Doric, Ionic, and Corinthian attached columns. At the Pitti Palace it provides an appropriately rural yet impressive backdrop for the gardens.

Two other major works by Ammannati in Florence are the Bridge of Santa Trinita (1567-69), which contains elliptical arches, and the Fountain of Neptune (1567-70; destroyed 1944, rebuilt 1957); the latter, in the Piazza della Signoria, features a colossal marble statue of that deity. In his old age Ammannati was strongly influenced by the Counter-Reformation philosophy of the Jesuits. He repudiated his earlier nude sculptures as lustful, and he designed several austere buildings for the Jesuits.

Ammassalik, also spelled ANGMAGSSALIK, town, southeastern Greenland, on the south coast of Ammassalik Island. The island is 25 miles (40 km) long and 12-20 miles (19-32 km) wide, with a high point of 4,336 feet (1,322 m). Although Europeans landed as early as 1472, the region was not explored until 1884, when Gustav Holm, a Dane, mapped the coast. A trading and mission station was established in 1895 to help sustain the Greenlandic (Eskimo) population with imported food and firearms for hunting. It was named for a fish called *angmagssat* (capelin) found in coastal waters. A weather and radio station is located there. Pop. (1990 est.) 1,465.

ammeter, instrument for measuring either direct or alternating electric current, in amperes. An ammeter can measure a wide range of current values because at high values only a small portion of the current is directed through the meter mechanism; a shunt in parallel with the meter carries the major portion.

Ammeters vary in their operating principles and accuracies. The D'Arsonval-movement ammeter measures direct current with accuracies of from 0.1 to 2.0 percent. The electrodynamic ammeter uses a moving coil rotating in the field produced by a fixed coil. It measures direct and alternating current with accuracies of from 0.1 to 0.25 percent. In the thermal ammeter, used primarily to measure alternating current with accuracies of from 0.5 to 3 percent, the measured current heats a thermoconverter (thermocouple); the small voltage thus generated is used to power a milli-

voltmeter. Digital ammeters, with no moving parts, use a circuit such as the dual slope integrator to convert a measured analogue (continuous) current to its digital equivalent. Many digital ammeters have accuracies better than 0.1 percent.

Ammianus Marcellinus (b. c. 330, Antioch, Syria [now Antakya, Tur.]—d. 395, Rome [Italy]), last major Roman historian, whose work continued the history of the later Roman Empire to 378.

Born of a noble Greek family, Ammianus served in the army of Constantius II in Gaul and Persia. He fought against the Persians under Julian the Apostate and took part in the retreat of his successor, Jovian. Leaving the army at Antioch, he traveled to Egypt and Greece, eventually settling in Rome. There he wrote his Latin history of the Roman Empire from the accession of Nerva to the death of Valens, thus continuing the work of Tacitus.

This history, *Rerum gestarum libri* ("The Chronicles of Events"), consisted of 31 books, of which only the last 18, covering the years 353-378, survive. It is a clear, comprehensive account of events by a writer of soldierly qualities, independent judgment, and wide reading. Drawing upon his own experience, Ammianus gave vivid pictures of the empire's economic and social problems. A pagan who was religiously tolerant, he took a detached view of the intellectual trends of the day. His judgment in political affairs was limited only by his own straightforward attitude. He used the regular techniques of later Roman historiography—rhetoric in his speeches, ethnographical digressions in descriptions, such as that of the culture of the Huns, and biographical conventions in character sketches along with fondness for literary allusion, overabundant metaphor, and much ornament. In conscious imitation of Tacitus, he wrote with vivid and striking dramatic power.

Ammon (Egyptian god): see Amon.

ammonia (NH₃), colourless, pungent gas composed of nitrogen and hydrogen. It is the simplest stable compound of these elements and serves as a starting material for the production of many commercially important nitrogen compounds. Pure ammonia was first prepared by Joseph Priestley in 1774, and its exact composition was determined by Claude-Louis Berthollet in 1785.

Ammonia is highly soluble in water, forming an alkaline solution called ammonium hydroxide. Moreover, it becomes highly reactive when dissolved in water and readily combines with many chemicals. Ammonia is easily liquefied by compression or by cooling to about -33° C (-27.4° F). In returning to the gaseous state, it absorbs substantial amounts of heat from its surroundings (*i.e.*, one gram of ammonia absorbs 327 calories of heat). Because of this property, it is frequently employed as a coolant in refrigerating and air-conditioning equipment.

The chief commercial method of producing ammonia is by the Haber-Bosch process, which involves the direct synthesis of the compound from its constituent elements. Ammonia from the Haber-Bosch process is supplemented by ammonia obtained as a by-product of coke ovens.

The major use of ammonia is as a fertilizer. It is most commonly applied directly to the soil from tanks containing the liquefied gas. Additional quantities are converted into ammonium nitrate, ammonium phosphate, and other salts that also are utilized primarily in commercial fertilizers. In the textile industry ammonia is used in the manufacture of synthetic fibres such as nylon and rayon. In addition, it is employed in the dyeing and scouring of cotton, wool, and silk. Ammonia serves as a catalyst in the production of Bakelite and some other synthetic resins. More im-

portantly, it neutralizes acidic by-products of petroleum refining, and in the rubber industry it prevents the coagulation of raw latex during transportation from plantation to factory. Ammonia also finds application in both the ammonia-soda, or Solvay, process, a widely used method for producing soda ash, and the Ostwald process, a method for converting ammonia into nitric acid. Ammonia is used in various metallurgical processes, including the nitriding of alloy sheets to harden their surfaces. Because ammonia can be decomposed easily to yield hydrogen, it is a convenient portable source of atomic hydrogen for welding. Finally, among its minor uses is inclusion in certain household cleansing agents.

ammonia-soda process, also called SOLVAY PROCESS, modern method of manufacturing the industrial alkali sodium carbonate, also known as soda ash. The process was devised and first put to commercial use by Ernest Solvay, who built a plant in Couillet, Belg., and was improved in the 1870s by the German-born British chemist Ludwig Mond.

In the ammonia-soda process, common salt, sodium chloride, is treated with ammonia and then carbon dioxide, under carefully controlled conditions, to form sodium bicarbonate and ammonium chloride. When heated, the bicarbonate yields sodium carbonate, the desired product; the ammonium chloride is treated with lime to produce ammonia for reuse and calcium chloride.

For some years after its introduction, the ammonia-soda process encountered stiff competition from the older Leblanc process, but it ultimately prevailed because it produced soda ash more cheaply.

Ammonite, any member of an ancient Semitic people whose principal city was Rab-bath Ammon, in Palestine. The "sons of Ammon" were in perennial, though sporadic, conflict with the Israelites. After a long period of seminomadic existence, the Ammonites established a kingdom north of Moab in the 13th century BC. With difficulty, their fortress capital was captured by Israel's King David. An Ammonite woman, one of many foreigners taken into Israel's King Solomon's harem, was responsible for inducing the king to worship the Ammonite god Malcom.

During the reign of Jehoiakim (6th century BC), the Ammonites allied themselves with the Chaldeans, Syrians, and others in an attack on Judah and also harassed the Israelites when they attempted to rebuild the Temple of Jerusalem after the Babylonian Exile. In the 2nd century BC they were defeated by Judas Maccabeus.

ammonium chloride (NH₄Cl), also called SAL AMMONIAC, the salt of ammonia and hydrogen chloride. Its principal use is as an electrolyte in dry cells, and it is also extensively employed as a constituent of galvanizing, tinning, and soldering fluxes to remove oxide coatings from metals and thereby improve the adhesion of the solders. It is a component of many proprietary cold medicines and cough remedies. Ammonium chloride is a colourless, crystalline substance. It is highly soluble in water, readily forming a slightly acidic solution. It vaporizes without melting at 340° C (644° F) to form equal volumes of ammonia and hydrogen chloride. Ammonium chloride is yielded as a by-product in the ammonia-soda process for making sodium carbonate. It also is produced by reaction of ammonium sulfate and sodium chloride solutions.

ammonium hydroxide, also called AQUA AMMONIA, solution of ammonia gas in water, a common commercial form of ammonia. It is a colourless liquid with a strong characteristic odour. In concentrated form, ammonium

hydroxide can cause burns on contact with the skin; ordinary household ammonia, used as a cleanser, is dilute ammonium hydroxide.

The water solution is generally represented by the formula NH_4OH , though no appreciable amount of the molecular species NH_4OH is present: the solution consists primarily of large quantities of water (H_2O) and ammonia (NH_3) and smaller quantities of ammonium ion, NH_4^+ , and hydroxide ion, OH^- .

ammonium nitrate (NH_4NO_3), a salt of ammonia and nitric acid, used widely in fertilizers and explosives. The commercial grade contains about 33.5 percent nitrogen, all of which is in forms utilizable by plants; it is the most common nitrogenous component of artificial fertilizers. Ammonium nitrate also is employed to modify the detonation rate of other explosives, such as nitroglycerin in the so-called ammonia dynamites, or as an oxidizing agent in the ammonals, which are mixtures of ammonium nitrate and powdered aluminum.

Ammonium nitrate is a colourless, crystalline substance (melting point $169.6^\circ C$ [$337.3^\circ F$]). It is highly soluble in water; heating of the water solution decomposes the salt to nitrous oxide (laughing gas). Because solid ammonium nitrate can undergo explosive decomposition when heated in a confined space, government regulations have been imposed on its shipment and storage.

Ammonius HERMIAE (fl. c. 550), Greek philosopher whose thinking was primarily oriented toward logic and the sciences. He spent a good part of his intellectual life in writing critical works on Aristotle. As a student, he worked closely with Proclus and, later in life, was appointed the head of the Alexandrian school. His major commentaries, on the *Categoriae* and *Analytica priora* of Aristotle's *Organon*, were well-respected down to the time of the Renaissance. He also wrote on some of the physical treatises of Aristotle.

ammonoid, any of a group of extinct cephalopods (of the phylum Mollusca), forms related to the modern pearly nautilus, that are frequently found as fossils in marine rocks

Polished cross section of a Middle Jurassic ammonoid from southern France; in the Eichstätt Museum, Eichstätt, Ger.

Lilly Stunzi, Zurich-New York

of the Devonian to the Cretaceous periods (408 to 66.4 million years ago). The ammonoids were shelled forms, many predacious in habit. Ammonoid shells, which are either straight or coiled, served as protective and supportive structures as well as hydrostatic devices, enabling the animal to compensate for varying water depths. Ammonoids are characterized and distinguished from nautiloids by the highly crenulated and complex suture that occurs where internal partitioning walls come in contact with the outer shell wall. Ammonoids are important index fossils because of their wide geographic distribution in

shallow marine waters, rapid evolution, and easily recognizable features. Three groups of ammonoids succeeded one another through time, each group having a more complex suture pattern. Ammonoids with a simple suture pattern, called goniatite, flourished during the Paleozoic Era (570 to 245 million years ago). Ammonoids characterized by a more highly folded suture, called ceratite, replaced the goniatites and were most abundant in the Triassic Period (245 to 208 million years ago). Most ammonoid genera became extinct at the end of that period, but a few survived and evolved into many diverse forms during the Cretaceous Period (144 to 66.4 million years ago). These forms are characterized by an interwoven suture called the ammonite pattern.

ammunition, the projectiles and propelling charges used in small arms, artillery, and other guns. Ammunition size is usually expressed in terms of calibre, which is the diameter of the projectile as measured in millimetres or inches. In general, projectiles less than 20 mm or .60 inch in diameter are classified as small-arm, and larger calibres are considered artillery. A complete round of ammunition consists of all the components necessary for one firing of the gun. These normally include a projectile, the propellant, and a primer that ignites the propellant. Other components such as cartridge case, fuze, and bursting charge are frequently included.

In artillery ammunition, a fixed round is a complete round in which all components are securely joined by a cartridge case. (Though brass was used almost invariably for cartridge cases before World War II, it has since been

- A fuze
- B shell
- C bursting charge
- D rotating band
- E cartridge case
- F propelling charge
- G primer

Three basic types of artillery ammunition

largely superseded by steel.) In semifixed ammunition, the projectile is detachable from the cartridge case, an arrangement that allows for the size of the propelling charge to be adjusted, after which the projectile can be inserted loosely into the case. In separate-loading ammunition, a complete round consists of three components: the fused projectile, the propellant (in several combustible cloth bags), and the primer. This type of round is used in the largest-calibre guns because its separated components are easier to handle.

Complete artillery rounds are further classified according to the type of projectile employed, such as high-explosive, armour-piercing, antipersonnel, nuclear, or chemical.

Some types of small-arms cartridges

By courtesy of (left) Sako Works, Riihimaki, Fin (centre left) Dynamit Nobel Aktiengesellschaft, Troisdorf, Ger (others) U.S. Department of the Army

Small-arms ammunition is always of the fixed type; complete rounds are usually called cartridges, and projectiles are called bullets (or shot in shotguns). Cartridge cases are most commonly made of brass, although steel is also widely used, and cases for shotgun pellets are made of brass and cardboard. The cases of most military rifles and machine guns have a bottleneck shape, allowing a small-calibre bullet to be fitted to a large propelling charge.

The most common type of military small-arms ammunition is called general-purpose in Britain and ball in the United States. The bullet of this type usually consists of a steel or lead-alloy core encased in a jacket of copper alloy or of mild steel coated with a copper alloy. Special-purpose ammunition includes armour-piercing rounds, which fire bullets that have cores of hardened steel or some other metal such as tungsten carbide. Tracer bullets have a column of pyrotechnic composition in the base that is ignited by the flame of the propellant; this provides a visible pyrotechnic display during the bullet's flight. Incendiary bullets, intended to ignite flammable materials such as gasoline, contain a charge of chemical incendiary agent. See also bullet; cartridge; gun powder; shell.

amnesia, loss of memory as a result of brain injury or deterioration, shock, fatigue, senility, drug use, alcoholism, anesthesia, illness, or psychoneurotic reaction. Amnesia may be anterograde, in which events following causative trauma or disease are forgotten; or retrograde, in which events preceding the causative event are forgotten.

The condition can often be traced to some severe emotional shock, in which case personal memories (e.g., identity), rather than less personal material (e.g., language skills), are affected. Such amnesia seems to represent a psychoneurotic escape from or denial of memories that might cause anxiety and is thus an example of repression, or motivated forgetting. These memories are not actually lost, since they can generally be recovered through psychotherapy or after the amnesic state has ended.

Occasionally amnesia may last for weeks, months, or even years, during which time the person may begin an entirely new life

pattern. Such protracted reactions are called fugue states. When recovered, the person is usually able to remember events that occurred prior to onset, but events of the fugue period are forgotten. Posthypnotic amnesia, the forgetting of most or all events that occur while under hypnosis in response to a suggestion by the hypnotist, has long been regarded as a sign of deep hypnosis.

The common difficulty of remembering childhood experiences is sometimes referred to as childhood amnesia.

amnesty, in criminal law, sovereign act of oblivion or forgetfulness (from Greek *amnēsia*) for past acts, granted by a government to persons who have been guilty of crimes. It is often conditional upon their return to obedience and duty within a prescribed period. Amnesty is granted usually for political crimes against the state, such as treason, sedition, or rebellion. It is addressed generally to classes or communities and takes the form of a legislative act or other constitutional or statutory act of the supreme power of the state. Thus in 1865 President Andrew Johnson issued a proclamation granting full pardon to all former Confederates (except certain leaders) who would take an unqualified oath of allegiance to the United States. Technically, however, an amnesty differs from a general pardon in that the latter simply relieves from punishment whereas the former declares innocence or abolishes the crime.

Amnesty International (AI), international organization headquartered in London that seeks to inform public opinion about violations of human rights, especially the abridgments of freedom of speech and of religion and the imprisonment and torture of political dissidents, and which actively seeks the release of political prisoners and the relief, when necessary, of their families. In 1977 Amnesty International was awarded the Nobel Prize for Peace.

The organization was founded in London on May 28, 1961, through the principal efforts of Peter Benenson, who had been a defense lawyer for political prisoners in Hungary, South Africa, and Spain and who sought to establish a collective agency for the advancement of human rights. From 1961 to 1975 the chairman of AI's International Executive Committee was Seán MacBride (recipient of the 1974 Nobel Prize for Peace). By the early 1980s AI consisted of an international secretariat of 150 persons, national "sections," or offices, in more than 40 countries, and about 200,000 individual members in some 100 countries.

Aside from generally publicizing governmental wrongdoing in newsletters, annual reports, and background papers, AI relies strongly on the worldwide distribution of "adoption groups," each of which, staffed by three to eight persons, takes on a limited number of cases of "prisoners of conscience" and bargains the offending government with letters of protest until the prisoners are released. The research department at London headquarters is in contact with human-rights activists and other interested parties around the world and provides the network of information for all the organization's activities.

Amnesty International's logo is a burning candle wrapped in barbed wire.

amniocentesis, the surgical insertion of a hollow needle through the abdominal wall and into the uterus of a pregnant female and the aspiration of fluid from the amniotic sac for analysis. Examination of the amniotic fluid itself as well as the fetal cells found in the fluid can reveal such things as fetal sex (the significant factor in inherited diseases that are sex-linked), chromosomal abnormality, and other types of potential problems. The procedure, generally carried out in the 15th to 17th week

of gestation, is relatively painless and can be carried out under local anesthesia.

Once used only in medical management of erythroblastosis fetalis (a blood disorder of the fetus and newborn that is caused by antibodies in the mother's blood), amniocentesis was first performed in the 1930s. More than 50 metabolic diseases can now be diagnosed by use of the procedure, but it is used most often for the identification of chromosomal anomalies and neural tube defects. It is also often recommended for women 35 years or older and for women who have experienced three or more spontaneous abortions.

amnion, in reptiles, birds, and mammals, a membrane forming a fluid-filled cavity (the amniotic sac) that encloses the embryo. The amniotic sac and the fluid it contains are sometimes referred to as the bag of waters.

In development, the amnion arises by a folding of a mass of extra-embryonic tissue called the somatopleure. Lined with ectoderm and covered with mesoderm (both are germ layers), the amnion contains a thin, transparent fluid in which the embryo is suspended, thus providing a cushion against mechanical injury. The amnion also provides protection against fluid loss from the embryo itself and against tissue adhesions.

Amoco Corporation, formerly (1889–1985) STANDARD OIL COMPANY (INDIANA), American petroleum corporation founded in 1889 by the Standard Oil trust (see Standard Oil Company and Trust) to direct the refining and marketing of oil in mid-continental states. In 1911 the U.S. Supreme Court dissolved the nationwide Standard Oil trust, and the Indiana company became independent. Its headquarters are in Chicago.

Following World War I, Standard Oil of Indiana acquired oil lands in Kansas, Louisiana, Arkansas, Wyoming, and Oklahoma in order to add production to its refining and marketing operations. Later it acquired interests in oil fields in Mexico and Venezuela (1925) and Canada (1949). In 1954 it acquired the entire assets of American Oil Company (founded 1910). In 1962 it created a subsidiary, American International Oil Company (now Amoco International Oil Company), which subsequently secured oil rights in the Gulf of Suez, the North Sea, and Trinidad. American operations, nevertheless, account for more than half of its total assets. Amoco has been active in some 40 other countries.

In addition to oil, Amoco's products include natural gas, chemicals, and minerals. Its retail trademark is Amoco.

amodiaquine, synthetic antimalarial drug introduced into medicine in the 1940s. A derivative of quinoline, the drug is administered orally as amodiaquine hydrochloride. It inhibits the development of the malarial parasites *Plasmodium vivax* and *P. falciparum* in the erythrocytic stage, in which they circulate in the bloodstream inside the red blood cells of the host. It is particularly effective against *P. falciparum*, but *P. vivax* is recurring. It is used less often than chloroquine for treatment of overt malaria. Possible side effects include nausea, vomiting, and diarrhea.

amoeba, also spelled AMEBA, plural AMOEBAS, or AMOEBAE, any of the microscopic unicellular protozoans of the rhizopodan order Amoebida. The well-known type species, *Amoeba proteus*, is found on decaying bottom vegetation of freshwater streams and ponds. There are numerous parasitic amoebas. Of six species found in the human alimentary tract, *Entamoeba histolytica* causes amoebic dysentery. Two related free-living genera of increasing biomedical importance are *Acanthamoeba* and *Naegleria*, strains of which have been recognized as disease-causing parasites in several vertebrates, including humans.

Amoebas are identified by their ability to

form temporary cytoplasmic extensions called pseudopodia, or false feet, by means of which they move about. This type of movement,

Amoeba (magnified)
Russ Kinne—Photo Researchers/EB Inc

called amoeboid movement, is considered to be the most primitive form of animal locomotion.

Amoebas are used extensively in cell research for determining the relative functions and interactions of the nucleus and the cytoplasm. Each amoeba contains a small mass of jelly-like cytoplasm, which is differentiated into a thin outer plasma membrane, a layer of stiff, clear ectoplasm just within the plasma membrane, and a central granular endoplasm. The endoplasm contains food vacuoles, a granular nucleus, and a clear contractile vacuole. The amoeba has no mouth or anus; food is taken in and material excreted at any point on the cell surface. During feeding, extensions of cytoplasm flow around food particles, surrounding them and forming a vacuole into which enzymes are secreted to digest the particles. Oxygen diffuses into the cell from the surrounding water, and metabolic wastes diffuse from the amoeba into the surrounding water. A contractile vacuole, which removes excess water from the amoeba, is absent in most marine and parasitic species. Reproduction is asexual (binary fission).

During adverse environmental periods many amoebas survive by encystment: the amoeba becomes circular, loses most of its water, and secretes a cyst membrane that serves as a protective covering. When the environment is again suitable, the envelope ruptures, and the amoeba emerges.

Amoghasiddhi (Sanskrit: "Unfailing Success"), in Mahāyāna and Vajrayāna (Tantric) Buddhism, one of the five "self-born" Buddhas. See Dhyāni-Buddha.

Āmol, also spelled AMUL, town, northern Iran, on the Harhāz River. The exact date of the founding of the town is unknown and enshrouded in legend, but it is certain that there

Mausoleum of Buzurjmihr, Āmol, Iran
Colin Wyatt—Photo Researchers/EB Inc

has been a town on the site since Sāsānian times. During the Sāsānian period, the district of Amol, together with the neighbouring district of Gilān, formed a Nestorian Christian episcopate. After the Arab conquest in the 8th century, the town became an important trading and scholarly centre, and it was the capital of the 'Abbāsīd province of Ṭabaristān, famous for its ceramic industry. Amol was sacked in the 11th century and again in the 14th by Timur (Tamerlane). It recovered, however, and an English traveler in the 17th century described it as a fruitful place with groves and well-built houses. Since then the town has suffered earthquake and flood damage several times but each time has recovered, and it is still a considerable town.

The modern town is slightly east of the extensive ruins of the old city, which includes the mausoleum of Buzurjmīhr, a semilegendary Sāsānian minister. The 17th-century structure is built on the foundations of a 10th-century one, which was destroyed by Timur. Oranges and rice are grown in the area, and there are nearby deposits of coal and iron. Pop. (1986) 118,242.

Amon, also spelled AMUN, AMEN, or AMMON, Egyptian deity who was revered as king of the gods.

Amon, bronze statue, c. 750–c. 550 BC; in the Brooklyn Museum
By courtesy of the Brooklyn Museum

Amon may have been originally a local deity at Khmun (Hermopolis) in Middle Egypt; his cult reached Thebes, where he became the patron of the pharaohs by the reign of Mentuhotep I (2008–1957 BC). At that date he was already identified with the sun god Re of Heliopolis and, as Amon-Re, was received as a national god. Represented in human form, sometimes with a ram's head, or as a ram, Amon-Re was worshiped as part of the Theban triad including a goddess, Mut, and a youthful god, Khons.

Amon's name meant The Hidden One, and his image was painted blue to denote invisibility. This attribute of invisibility led to a popular belief during the New Kingdom (1539–c. 1075 BC) in the knowledge and impartiality of Amon, making him a god for those who felt oppressed.

Amon's influence was, in addition, closely linked to the political well-being of Egypt. During the Hyksos domination (c. 1630–c. 1523 BC), the princes of Thebes sustained his worship. Following the Theban victory over the Hyksos and the creation of an em-

pire, Amon's stature and the wealth of his temples grew. In the late 18th dynasty Akhenaton (Amenhotep IV) directed his religious reform against the traditional cult of Amon, but he was unable to convert people from their belief in Amon and the other gods; and, under Tutankhamen, Ay, and Horemheb (1332–1292 BC), Amon was gradually restored as the god of the empire and patron of the pharaoh.

In the New Kingdom, religious speculation among Amon's priests led to the concept of Amon as part of a triad (with Ptah and Re) or as a single god of whom all the other gods, even Ptah and Re, were manifestations. Under the sacerdotal state ruled by the priests of Amon at Thebes (c. 1075–c. 950 BC), Amon evolved into a universal god who intervened through oracles in many affairs of state.

The succeeding 22nd and 23rd dynasties, the invasion of Egypt by Assyria (671–c. 663 BC), and the sack of Thebes (c. 663 BC) did not reduce the stature of the cult, which had acquired a second main centre at Tanis in the Nile River delta. Moreover, the worship of Amon had become established among the Cushites of the Sudan, who were accepted by Egyptian worshippers of Amon when they invaded Egypt and ruled as the 25th dynasty (715–664 BC). From this period onward, resistance to foreign occupation of Egypt was strongest in Thebes. Amon's cult spread to the oases, especially Siwa in Egypt's western desert, where Amon was linked with Jupiter. Alexander the Great won acceptance as pharaoh by consulting the oracle at Siwa, and he also rebuilt the sanctuary of Amon's temple at Luxor. The early Ptolemaic rulers contained Egyptian nationalism by supporting the temples, but, starting with Ptolemy IV Philopator in 207 BC, nationalistic rebellions in Upper Egypt erupted. During the revolt of 88–85 BC, Ptolemy IX Soter II sacked Thebes, dealing Amon's cult a severe blow. In 27 BC a strong earthquake devastated the Theban temples, while in the Greco-Roman world the cult of Isis and Osiris gradually displaced Amon.

Amontons, Guillaume (b. Aug. 31, 1663, Paris, France—d. Oct. 11, 1705, Paris), French physicist and inventor of scientific instruments, best known for his work on friction and temperature measurement.

Amontons is often credited with having discovered the laws of friction (1699), though in fact his work dealt solely with static friction—*i.e.*, the friction of objects at rest. It was only after the English physicist Sir Isaac Newton formulated his laws of motion that the friction of moving bodies was analyzed.

Amontons also developed an air-pressure thermometer (1702) and published two notable papers on thermometry (1702–03). He devised a method of measuring a change in temperature in terms of a proportional change in pressure of a constant mass and volume of air. This method eventually led to the concept of the absolute zero of temperature in the 19th century.

amora (Hebrew and Aramaic: “interpreter,” or “reciter”), plural AMORAIM, in ancient times, a Jewish scholar attached to one of several academies in Palestine (Tiberias, Sephoris, Caesarea) or in Babylonia (Nehardea, Sura, Pumbedita). The amoraim collaborated in writing the Gemara, collected interpretations of and commentaries on the Mishna (the authoritative code of Jewish oral laws) and on its critical marginal notes, called Tosefta (Addition). The amoraim were thus the successors of earlier Jewish scholars (tanaim), who produced the Mishna and were themselves the creators of the Talmud (the Mishna accompanied by the Gemara). Writing in various Aramaic dialects interspersed with Hebrew, the two groups of amoraim began work about AD 200 on the Gemara section of the Talmud. Because the Babylonian amoraim worked about a century longer than

their counterparts in Palestine, completing their work about AD 500, the *Talmud Bavli* (“Babylonian Talmud”) was more comprehensive and, consequently, more authoritative than the *Talmud Yerushalmi* (“Palestinian Talmud”), which lacks the Babylonian interpretations. In Palestine an ordained amora was called a rabbi; in Babylonia, a *rav*, or *mar*. See also Talmud.

Amorbach, city, Bavaria Land (state), southwestern Germany, in the Odenwald (wooded upland), southwest of Würzburg. It originated around a Benedictine monastery in the 8th century and came under the jurisdiction of the electors of Mainz in 1272. Amorbach became the residence of the princes of Leiningen in 1803 and passed to Bavaria in 1816. The modern city is a health resort and has wood-working and textile industries as well. Pop. (1991 est.) 4,317.

Amorgós Island, modern Greek Νίσος AMORGÓS, island trending northeast-southwest in the Cyclades (Kiklādhēs) group of the Greek Aegean Islands. For the most part mountainous and narrow, it has an area of about 47 square miles (121 square km). Prosperous in the early Bronze Age, in classical times it had three cities, Arcesine, Minoa, and Aegiale. The island produced *amorgina*, fine transparent fabrics made from locally grown flax or cotton. It was used by the Romans as a place for exiles. Today it supports a dwindling agricultural community, chiefly in the Katápolā Plain, which has the only good anchorage for visitors. The principal village is Amorgós (Chora) on the southern coast. There are also two ports on the northern coast, Katápolā and Aiyiáli (Hagios Nicolaos). The latter is situated near the ruins of ancient Amorgós, about 9 miles (14 km) from modern Amorgós. Pop. (1981) 1,718.

Amorite, member of an ancient Semitic-speaking people who dominated the history of Mesopotamia, Syria, and Palestine from about 2000 to about 1600 BC. In the oldest cuneiform sources (c. 2400–c. 2000 BC), the Amorites were equated with the West, though their true place of origin was most likely Arabia, not Syria. They were troublesome nomads and were believed to be one of the causes of the downfall of the 3rd dynasty of Ur (c. 2112–c. 2004 BC).

During the 2nd millennium BC the Akkadian term Amurru referred not only to an ethnic group but also to a language and to a geographic and political unit in Syria and Palestine. At the beginning of the millennium, a large-scale migration of great tribal federations from Arabia resulted in the occupation of Babylonia proper, the mid-Euphrates region, and Syria-Palestine. They set up a mosaic of small kingdoms and rapidly assimilated the Sumero-Akkadian culture. It is possible that this group was connected with the Amorites mentioned in earlier sources; some scholars, however, prefer to call this second group Eastern Canaanites, or Canaanites.

Almost all of the local kings in Babylonia (such as Hammurabi of Babylon) belonged to this stock. One capital was at Mari (modern Tall al-Ḥarīrī, Syria). Farther west, the political centre was Ḥalab (Aleppo); in that area, as well as in Palestine, the newcomers were thoroughly mixed with the Hurrians. The region then called Amurru was northern Palestine, with its centre at Hazor, and the neighbouring Syrian desert.

In the dark age between about 1600 and about 1100 BC, the language of the Amorites disappeared from Babylonia and the mid-Euphrates; in Syria and Palestine, however, it became dominant. In Assyrian inscriptions from about 1100 BC, the term Amurru designated part of Syria and all of Phoenicia and Palestine but no longer referred to any specific kingdom, language, or population.

Amorite language, one of the most ancient of the archaic Semitic languages, distributed in an area that is now northern Syria. Amorite is known almost exclusively from glosses and names, and the only known grammar is the grammar of names. Despite the unknown linguistic characteristics, Amorite is dated from the known chronology of proper names of the period in the last century of the 3rd millennium BC. It was probably the language of the seminomads of the West Semitic area. As a Northern Central Semitic language, Amorite is affiliated with the Hamito-Semitic family of languages.

Amoroso Lima, Alceu, pseudonym TRISTÃO DE ATHAYDE (b. Dec. 11, 1893, Rio de Janeiro, Brazil—d. Aug. 15, 1983, Rio de Janeiro), essayist, philosopher, and literary critic, a leading force in the Neo-Catholic intellectual movement in Brazil. He was also an enthusiastic supporter of the Modernist cultural movement of the 1920s.

Amoroso Lima's multifaceted career included positions as professor of sociology, law, and literature, university president, literary critic for the *Jornal do Brasil* and numerous other periodicals, and director of the Cultural Division of the Pan American Union in Washington, D.C. (1951–53). He was a founder of the Agir Publishing House (1944) and was elected to the Brazilian Academy of Letters (1935). In 1957 he cofounded the Latin American Christian Democrat Movement.

Examples of his varied publications are *Contra-revolução espiritual* (1932; "The Spiritual Counter-Revolution"), *Problema da burguesia* (1932; "The Problem of the Bourgeoisie"), *Mitos de nosso tempo* (1943; "Myths of Our Time"), *Humanismo pedagógico* (1944; "Pedagogical Humanism"), an exposition of Christian humanism, and *Revolução, reação ou reforma* (1964; "Revolution, Reaction, or Reform").

amortization, in finance, the systematic repayment of a debt; in accounting, the systematic writing off of some account over a period of years.

An example of the first meaning is a mortgage on a home, which may be repaid in monthly installments that include interest and a gradual reduction of the principal obligation. Such systematic annual reduction increases the safety factor for the lender by imposing a small annual burden rather than a single, large, final obligation.

In the second sense, the amortization of an asset, such as a building, a machine, or a mine, over its estimated life has the effect of reducing its balance-sheet valuation and charging its cost into the expenses of operation. Such expense is called depreciation or, for exhaustible natural resources, depletion. Some assets, such as property that is abandoned or lost in a catastrophe, may continue to be carried among the firm's assets until their extinction is achieved by gradual amortization.

Accelerated amortization was permitted in the United States during World War II and extended after the war to encourage business to expand productive facilities that would serve the national defense. In the 1950s, accelerated amortization encouraged the expansion of export and new product industries and stimulated modernization in Canada, western European nations, and Japan. Other countries have also shown interest in it as a means of encouraging industrial development, but the current revenue lost by the government is a more serious consideration for them.

The advantage of accelerated amortization for tax purposes lies in the deferment of taxes rather than in their reduction. When amortization is accelerated, the drain of income taxes is reduced for the business during the years immediately after the purchase, thus releasing more funds for the repayment of any

obligations incurred in financing the property. A financial problem may result later from the absence of any deduction in the normal income taxes for depreciation. Income-tax expenses can be equalized, however, by treating taxes not paid in the early years as a deferred tax liability.

Amory, Thomas (b. 1691?—d. Nov. 25, 1788, London, Eng.), British writer of Irish descent, best known for his extravagant "au-

Amory, detail of an engraving by Hopwood after a drawing by G. Baxter
Mary Evans Picture Library London

tobiography," *The Life of John Bunce*, 2 vol. (1756 and 1766), in which the hero marries seven wives in succession, each wife embodying one of Amory's ideals of womanhood. Rich, racy, and eccentric, his works contain something of the spirit of both Charles Dickens and François Rabelais.

A staunch Unitarian and a student of medicine, geology, and antiquities, Amory filled his writings with a variety of information on these and other subjects. He is thought to have lived in Dublin (where he knew the satirist Jonathan Swift) and later at Westminster.

Amos (fl. 8th century BC), the first Hebrew prophet to have a biblical book named for him. He accurately foretold the destruction of the northern kingdom of Israel (although he did not specify Assyria as the cause) and, as a prophet of doom, anticipated later Old Testament prophets.

The little that is known about Amos' life has been gleaned from his book, which was, in all likelihood, partly or wholly compiled by other hands. A native of Tekoa (now a ruin), 12 miles (19 km) south of Jerusalem, Amos flourished during the reigns of King Uzziah (c. 783–742 BC) of Judah (the southern kingdom) and King Jeroboam II (c. 786–746 BC) of Israel. By occupation, he was a shepherd; whether he was merely that or a man of some means is not certain. He actually preached for only a short time.

Under the impact of powerful visions of divine destruction of the Hebrews in such natural disasters as a swarm of locusts and fire, Amos traveled from Judah to the neighbouring richer, more powerful kingdom of Israel, where he began to preach. The time is uncertain, but the Book of Amos puts the date as two years before an earthquake that may have occurred in 750 BC. Amos fiercely castigated corruption and social injustice among Israel's pagan neighbours, Israel itself, and Judah; he asserted God's absolute sovereignty over man; and he predicted the imminent destruction of Israel and Judah. After preaching at Bethel, a famous shrine under the special protection of Jeroboam II, Amos was ordered to leave the country by Jeroboam's priest Amaziah. Thereafter his fate is unknown.

From his book, Amos emerges as a thoughtful, probably well-traveled man of fierce integrity, who possessed a poet's gift for homely but forceful imagery and rhythmic language. So distinctive is his style of expression that in many instances the reader can distinguish those portions genuinely by Amos from parts

probably invented by others, such as the concluding, optimistic section foretelling the restoration of the Davidic kingdom.

As a theologian, Amos believed that God's absolute sovereignty over man compelled social justice for all men, rich and poor alike. Not even God's chosen people were exempt from this fiat, and even they had to pay the penalty for breaking it; hence, Amos also believed in a moral order transcending nationalistic interests.

Amos, Book of, the third of 12 Old Testament books that bear the names of the Minor Prophets, collected in one book under the Jewish canon titled *The Twelve*. Amos, a Judean prophet from the village of Tekoa, was active in the northern kingdom of Israel during the reign of Jeroboam II (c. 786–746 BC). According to 7:14, Amos was neither a prophet nor the son of a prophet; *i.e.*, he was not a member of a professional prophetic guild. His only credential to prophesy to Israel was a summons by Yahweh.

The book is a collection of individual sayings and reports of visions. Whether Amos himself committed any of his sayings to writing is not certain; his words may have been recorded by a scribe from Amos' dictation or by a later writer who knew the sayings from oral tradition. The present arrangement of the sayings reflects the activity of someone other than the prophet.

Amos' message is primarily one of doom. Although Israel's neighbours do not escape his attention, his threats are directed primarily against Israel, which, he contends, has defected from the worship of Yahweh to the worship of Canaanite gods. This belief prompts his polemic against the feasts and solemn assemblies observed by Israel. He also pronounces judgment on the rich for self-indulgence and oppression of the poor, on those who pervert justice, and on those who desire the day of Yahweh on which God will reveal his power, punish the wicked, and renew the righteous. That day, Amos warned, will be a day of darkness for Israel because of its defection from Yahweh.

The book ends unexpectedly (9:8–15) with a promise of restoration for Israel. Because these verses so radically differ from the threatening nature of the rest of the book, many scholars believe them to be a later addition.

amosite, a variety of the silicate mineral cummingtonite, which is a source of asbestos (*see* cummingtonite).

amour courtois: *see* courtly love.

Amoy, Wade-Giles romanization HSIA-MEN, Pinyin XIAMEN, city and port on the coast of southern Fukien *sheng* (province), China. Amoy is situated on the southwest coast of Hsia-men Island at the mouth of the Chiu-lung River. Known as the "garden on the sea," it has an excellent harbour, sheltered by a number of offshore islands, the most important of which, Quemoy (Chin-men), in the mouth of the estuary, has remained a fortress in the hands of the Chinese Nationalist government on Taiwan.

During the Sung (960–1279) and Yüan (1279–1368) dynasties, Amoy was known as Chia-shu Island and formed a part of T'ung-an county. It was notable chiefly as a lair of pirates and a centre of contraband trade. The name Hsia-men first appeared when the island was fortified as one of a series of measures taken against piracy in 1394. During the 1600s it was under the control of Cheng Ch'eng-kung, or Koxinga (1624–62), the ruler of Taiwan, at which time it was called Ssu-ming prefecture. In 1680 it was taken by the forces of the Ch'ing dynasty (1644–1911), after which it became the headquarters of the Ch'üan-chou

naval defense force. Foreign trade there began with the arrival of the Portuguese in 1544, but they were expelled shortly thereafter. Under Cheng Ch'eng-kung's rule, English and Dutch ships had called at Amoy; and British traders continued occasionally to visit Amoy until 1757, when trade was restricted to Canton. After the Opium War of 1839-42 between Britain and China, Amoy was one of the first five ports to be opened to foreign trade and to residence by foreigners. A foreign settlement grew up on Ku-lang Island, in the harbour. Amoy in the 19th century was preeminently a tea port, exporting teas from southeastern Fukien. The peak of this trade was reached in the 1870s but then declined, after which Amoy became the chief market and shipping port for Taiwanese tea produced by local growers who had emigrated to that island.

In the later 19th century, Amoy was the base from which Taiwan was settled and exploited; and the port retained a close link with the island even after the Japanese conquest of Taiwan in 1895; it also was one of the chief ports of departure for Chinese emigrants settling elsewhere in Southeast Asia. With the decline of the tea trade in the early 20th century, Amoy continued to export canned fruits, canned fish, paper, sugar, and timber. From 1938 to 1945 Amoy was occupied by the Japanese.

After 1949 considerable development took place. A causeway was built in 1956, linking the island to the mainland, and a railway line was constructed from Amoy to the border of Chekiang province, with a branch to Fu-chou. The railway was completed in 1956. Industrial development since 1949 has consisted chiefly of light industry. The canning of fruit and fish, the production of cod-liver oil, fish meal, and other fish products, and sisal processing, sugar refining, tanning, and tobacco curing are important industries. There is also a sizable ship repairing and engineering industry. In the 1980s Amoy was made a special economic zone, its harbour and its airport both expanded. The city has a university that was founded in 1921. Pop. (1990) 386,786.

ampere, unit of electric current in the Système International d'Unités (SI), used by both scientists and technologists. Since 1948 the ampere has been defined as the constant current which, if maintained in two straight parallel conductors of infinite length of negligible circular cross section and placed one metre apart in a vacuum, would produce between these conductors a force equal to 2×10^{-7} newton per metre of length. Named for the 19th-century French physicist André-Marie Ampère, it represents a flow of one coulomb of electricity per second. A flow of one ampere is produced in a resistance of one ohm by a potential difference of one volt. See electric current.

Ampère, André-Marie (b. Jan. 22, 1775, Lyon, France—d. June 10, 1836, Marseille), French physicist who founded and named the science of electrodynamics, now known as electromagnetism.

Ampère was a prodigy who mastered all mathematics then extant by the time he was 12 years old. He became a professor of physics and chemistry at Bourg in 1801 and a professor of mathematics at the École Polytechnique in Paris in 1809.

Ampère was not a methodical experimenter; he was subject to brilliant flashes of inspiration, which he would then pursue to their conclusion. For example, when he learned of Danish physicist Hans Christian Ørsted's discovery in 1820 that a magnetic needle is deflected when the current in a nearby wire varies—a phenomenon establishing a relationship between electricity and magnetism—

André-Marie Ampère, detail of an oil painting by an unknown artist
The Mansell Collection

Ampère prepared within a week the first of several papers fully expounding the theory of this new phenomenon. He formulated a law of electromagnetism (commonly called Ampère's law) that describes mathematically the magnetic force between two electric currents. He also performed many experiments, the results of which served to develop a mathematical theory that not only explained electromagnetic phenomena already reported but predicted new ones as well. The first person to develop measuring techniques for electricity, Ampère built an instrument utilizing a free-moving needle to measure the flow of electricity. Its later refinement was known as the galvanometer. His chief published work appeared in 1827 as *Memoir on the Mathematical Theory of Electrodynamical Phenomena, Uniquely Deduced from Experience*.

Ampère, Jean-Jacques (-Antoine) (b. Aug. 12, 1800, Lyon, France—d. March 27, 1864, Pau), French historian and philologist who initiated important studies of the diverse cultural origins of western European languages and mythology. A world traveler, he wrote both scholarly works and Romantic poetry.

The son of the scientist André-Marie Ampère, Jean-Jacques Ampère in 1826 made his first journey to Germany, where his work greatly impressed the poet and philosopher J.W. von Goethe. On the basis of his study of Scandinavian mythology, Ampère was named to a chair in the history of foreign literature at the Sorbonne in Paris in 1830; three years later he became a professor at the Collège de France, where he did the research for his major philological works, *Histoire littéraire de la France avant le douzième siècle*, 3 vol. (1839-40; "History of French Literature before the 12th Century"), and *Histoire de la formation de la langue française* (1841; "History of the Development of the French Language"). In his theories of environmental influences on history, he was a precursor of the French critic and historian Hippolyte Taine. His personal life was largely dominated by his platonic love for the famous beauty and hostess Madame de Récamier, who was much older than he; Ampère carried on a long correspondence with her and was a habitué of her salon. In 1848 he was elected to the French Academy. In the company of the writer Prosper Mérimée, he visited the Middle East and, later, the United States and Mexico. Ampère's major historical work is *L'Histoire romaine à Rome*, 4 vol. (1861-64; "Roman History in Rome"); his other diverse works include *De l'histoire de la poésie* (1830; "On the History of Poetry") and *Promenade en Amérique: États-Unis, Cuba et Mexique* (1855; "Travels in America: The United States, Cuba, and Mexico").

Ampère's law, one of the basic relations between electricity and magnetism, stating quantitatively the relation of a magnetic field to the electric current or changing electric field that produces it. The law is named in honour of André-Marie Ampère, who by 1825 had laid the foundation of electromagnetic theory. An

alternative expression of the Biot-Savart law ($q \cdot v$), which also relates the magnetic field and the current that produces it, Ampère's law is generally stated formally in the language of calculus: the line integral of the magnetic field around an arbitrarily chosen path is proportional to the net electric current enclosed by the path. James Clerk Maxwell is responsible for this mathematical formulation and for the extension of the law to include magnetic fields that arise without electric current, as between the plates of a capacitor, or condenser, in which the electric field changes with the periodic charging and discharging of the plates but in which no passage of electric charge occurs. Maxwell also showed that even in empty space a varying electric field is accompanied by a changing magnetic field. The complete Ampère's law describes all these effects.

amphetamine, prototype of a series of synthetic drugs, all called amphetamines, that have pronounced stimulatory actions on the central nervous system. Amphetamine itself is a colourless liquid with an acrid taste and a faint odour; the most widely used preparation of the drug is amphetamine sulfate, marketed under the name Benzedrine, a white powder with a slightly bitter, numbing taste. Dextroamphetamine sulfate, marketed under the name Dexedrine, is the more active of the two optically isomeric forms in which amphetamine exists. Other members of the amphetamine series include methamphetamine ($q.v.$) and benzphetamine.

These drugs partially reverse the depressant effects of anesthetics, narcotics, hypnotics, and alcohol. All amphetamines cause profound psychic effects, including wakefulness, mental alertness, increased initiative and confidence, euphoria, lessened sense of fatigue, talkativeness, and increased ability to concentrate.

Amphetamine effectively dulls the appetite when taken before meals, so it is widely used as an adjunct to dietary restriction in weight reduction. It is used (sometimes illicitly) by pilots, truckers, and soldiers on long-term missions where prolonged wakefulness is required. The amphetamines have had a major role in the management of hyperactive children because the drugs calm such children and enable them to concentrate, usually within a day after treatment is begun. Amphetamines have also been used in the treatment of narcolepsy.

Amphetamines can produce undesirable effects, the most common of which is overstimulation, with restlessness, insomnia, tremor, tenseness, and irritability. Physical tolerance to amphetamines develops rapidly, so that progressively larger doses must be consumed by the chronic user. The letdown effect that occurs in such users after the drug has worn off consists of a deep mental depression. The most severe aftereffect of large doses of amphetamines is a toxic psychosis whose symptoms resemble those of paranoid schizophrenia. Amphetamine addiction frequently is associated with similar abuse of barbiturates and alcohol.

amphibian, any member of a class (Amphibia) of cold-blooded vertebrate animals that are midway in evolutionary development between fishes and reptiles. Included among the more than 4,400 living species are the frogs and toads, salamanders and newts, and caecilians.

A brief treatment of amphibians follows. For full treatment, see MACROPAEDIA: Amphibians.

Amphibians (from Greek *amphi*, "both"; *bios*, "life") were the first vertebrates to move from an aquatic environment to land, and they are the ancestors of all reptiles, birds, and mammals. Although a few species spend their lives in water, most live at least part of the time on land. They are distributed worldwide, but the majority are found in the tropics.

Most amphibians have an aquatic larval, or

tadpole, stage that metamorphoses into a terrestrial adult. In caecilians and salamanders, fertilization is usually internal. The male caecilian introduces sperm into the female by means of a protrusible portion of the cloaca, the lower end of the digestive track. The male salamander deposits sperm on a gelatinous structure, which the female maneuvers into her cloaca. Fertilization is external in most frogs and toads, with the male clasping the female and releasing sperm over the eggs as the female extrudes them (amplexus). The eggs of amphibians do not have shells and must be deposited in water or in a moist place, such as damp soil or on a female's back.

There are three living groups of amphibians, all of which differ markedly in structure. The caecilians (order Apoda, or Gymnophiona of some authorities) are burrowing, wormlike animals that have no limbs, practically no tail, a simple intestine, and minute eyes buried in a smooth skin. They are confined to moist habitats in the tropics.

The salamanders and newts (order Caudata) belong to a second group, prevalent in the southeastern United States and in Mexico. Salamanders have forelegs, hindlegs, a tail, smooth skin, and a neck. Teeth are found on the jaws and roof of the mouth. Some species remain in the water as permanent larvae with gills. The sirens, one of the two aquatic genera of salamanders, are elongated aquatic animals without hindlimbs but with anterior pectoral girdles to which the front legs are attached. They breathe through gills or gulp air at the surface. The eyes are buried in the smooth skin, and teeth are attached to the roof of the mouth. Tail fins assist locomotion.

Frogs and toads (order Anura) constitute the largest group of amphibians. These animals are distinguished by a segment in the hindleg, formed by two elongated tarsal bones, that is used for hopping and swimming. Teeth are usually found in the upper jaw. The glandular skin, usually smooth and soft, is occasionally dry and rough in terrestrial species.

Amphibians are believed to have evolved from either the lobe-fin fishes (Crossopterygii) or the lungfishes (Dipnoi) of the Early Devonian Period (408 to 387 million years ago). These fishes had lungs, muscular fins supported by bones, and, in some species, passages from nasal sacs to internal openings in the roof of the mouth. In time of drought, these creatures probably propelled themselves out of the drying pools on their muscular fins to search for other water. They then perhaps added insects and other small arthropods to their diet and became less dependent on water. A single caecilian fossil from the Paleocene Epoch (66.4 to 57.8 million years ago) has been found in Brazil. Fossils of sirens have been found in rocks of the Cretaceous Period (144 to 66.4 million years ago) and salamanders in rocks of the Jurassic Period (208 to 144 million years ago). Both sirens and salamanders apparently evolved in the Northern Hemisphere, but the earliest frogs, dating from the Jurassic Period, evolved south of the Equator.

amphibious vehicle, device for transporting personnel and equipment, usually military, that can operate as a wheeled or tracked vehicle on land and as a boat in water. Two principal types appeared during World War II: the LVT ("landing vehicle, tracked"), a tractor developed for the U.S. Marine Corps, and the "duck" (DUKW), an army-sponsored vehicle. The LVT resembled a tank, whereas the duck moved on rubber tires ashore and was propeller-driven when afloat. An air-cushion machine, such as the British Hovercraft, is not considered an amphibious vehicle.

amphibious warfare, military operations characterized by attacks launched from the sea by naval and landing forces against hostile shores. The main form is the amphibious

assault, which may be conducted for any of several purposes: to serve as a prelude to further combat operations ashore; to seize a site required as an advanced naval or air base; or to deny the use of the site or area to the enemy. Landing of expeditionary forces on a shore or at a port already secured by friendly forces is not usually included in the concept.

Amphibious warfare has been conducted since ancient times, although specialized landing vessels are a modern development. The Greeks attacking Troy (1200 BC) had to gain a lodgment on the shore, as did the Persian invaders of Greece in the Bay of Marathon (490 BC). After the decline of Rome and during the European Middle Ages, the most successful practitioners of amphibious warfare, although on a small scale, were the Norse raiders on the coasts of northern, western, and Mediterranean Europe. During the Napoleonic Wars, Napoleon's failure to control the English Channel and invade England is frequently cited as a classic example of the inability of a strong continental force to project its strength over even the narrowest of seas if it lacks sea power. Similarly, Germany was disadvantaged during World War II by its lack of adequate amphibious capability.

The British-led landings at Gallipoli (1915) during the disastrous Dardanelles Campaign was the principal amphibious assault during World War I. By contrast, the Allies' counteroffensives in World War II (with the exception of those of the Soviet Union) were predicated upon a series of amphibious operations that were essential to reentering Axis-held territory. The United States' island-hopping campaigns westward across the Pacific involved amphibious assaults against the Japanese-held islands of Guadalcanal in the Solomons, New Guinea, Kwajalein, Tarawa, the Marianas, the Philippines, Iwo Jima, and Okinawa. In the Western theatre, the Normandy Invasion (1944), in which Allied forces successfully invaded the German-held coast of northern France, ranks as the greatest amphibious assault in history. The outstanding example of amphibious warfare in the Korean War was the landing of U.S. forces at Inchon on the west coast of Korea in 1950.

Modern amphibious warfare integrates virtually all forms of land, sea, and air operations. Its greatest advantage lies in its mobility and flexibility; its greatest limitation is that the attacker must build up his strength ashore from an initial zero. After World War II, new debarkation methods and capabilities were developed to overcome the previously slow and ponderous off-loading process. Helicopters were used for resupply and medical evacuation, as well as for landing troops. To improve tactical air support in the battle area, airfields were developed that in a matter of days provided substantially the same capabilities ashore as an attack aircraft carrier.

amphibole, any of a group of common rock-forming silicate minerals. Amphiboles occur in most igneous rocks as minor and major constituents and form the major component in many metamorphic gneisses and schists. (See Table, page 352.)

A brief treatment of amphiboles follows. For full treatment, see MACROPAEDIA: Minerals and Rocks.

The amphiboles are inosilicates. They have two planes of well-developed prismatic cleavages that intersect at angles of about 124° and 56°. Many amphiboles develop elongate crystals, some becoming needlelike and fibrous. Several of these fibrous forms—riebeckite, cummingtonite, anthophyllite, and tremolite—are collectively called asbestos. In general, amphiboles crystallize in either the orthorhombic or monoclinic system.

The amphiboles show considerable variation in composition. Besides silicon (Si) and oxygen (O), their components include sodium

(Na), calcium (Ca), magnesium (Mg), iron (Fe), aluminum (Al), hydrogen (H), and fluorine (F). The general chemical formula of the amphibole group may be expressed as:

The amphibole structure consists of double chains of silicon-oxygen tetrahedrons in which alternate tetrahedrons link two single chains by sharing an oxygen atom. The double-chain groups are bonded to parallel adjacent double chains by the Na, Ca and Mg, Fe²⁺, Fe³⁺, Al ions of the crystal. There are only small differences between the ionic sizes of Mg, Fe²⁺, Fe³⁺, and Al, so that the positions in the crystal that are occupied by Mg can also be occupied by these similarly sized ions (*i.e.*, they can substitute for each other). The ionic sizes of Ca and Na are similar enough that they can substitute for each other. Moreover, the ionic size of Al is close enough to the size of Si that a limited Al substitution for Si occurs.

amphibole asbestos, a variety of the silicate mineral actinolite (*q.v.*).

amphibolite, a rock composed largely or dominantly of minerals of the amphibole group. The term has been applied to rocks of either igneous or metamorphic origin. In igneous rocks, the term hornblendite is more common and restrictive; hornblende is the most common amphibole and is typical of such rocks. Hornblendite is an ultramafic rock (dominantly dark minerals) and is also ultrabasic (low in silica content). True hornblendites contain little other than amphibole and are probably derived from the alteration of pyroxene and olivine.

Metamorphic amphibolites are a more widespread and variable group of rocks formed through metamorphism. Typically, they are medium- to coarse-grained and are composed of hornblende and plagioclase. These are the diagnostic rocks of the amphibolite facies of regional metamorphism and may be derived from premetamorphic rocks of various types. Basic igneous rocks (*e.g.*, basalts and gabbros) and sedimentary dolomite can be the parent rocks of amphibolite.

amphibolite facies, one of the major divisions of the mineral-facies classification of metamorphic rocks, the rocks of which formed under conditions of moderate to high temperatures (500° C, or about 950° F, maximum) and pressures. Less intense temperatures and pressures form rocks of the epidote-amphibolite facies, and more intense temperatures and pressures form rocks of the granulite facies. Amphibole, diopside, epidote, plagioclase, almandite and grossularite garnet, and wollastonite are minerals typically found in rocks of the amphibolite facies. The disappearance of epidote and increase in calcium in plagioclase are characteristic chemical changes as metamorphic intensity increases through this facies. Water is usually lost from the parent rock as these changes take place. Amphibolite facies rocks are widely distributed in Precambrian gneisses (those 540 million to 3.8 billion years old); they are interpreted as having formed in the deeper parts of folded mountain belts.

amphictyony, also spelled AMPHICTYONY (from Greek *amphiktyones*, "dwellers around"), in ancient Greece, association of neighbouring states formed around a religious centre. The most important was the Amphictyonic League (Delphic Amphictyony). Originally composed of 12 tribes dwelling around Thermopylae, the league was centred first on the shrine of Demeter and later became associated with the Temple of Apollo at Delphi. Member states sent two kinds of deputies

(*pylagoras* and *hieromnēmones*) to a council (*pylana*) that met twice a year and administered the temporal affairs of the shrines and their properties, supervised the treasury, and conducted the Pythian Games. In the 4th century BC the league rebuilt the Delphic temple. Although primarily religious, the league exercised a political influence through its membership oath, forbidding destruction of member cities or the cutting off of water supplies; the *hieromnēmones* could punish offenders and even proclaim a sacred war against them. Other important amphictyonies were the Delian and, in the Archaic period, the Calaurian (composed of states around the Saronic Gulf).

Amphion and Zethus, in Greek mythology, the twin sons of Zeus by Antiope. When children, they were left to die on Mount Cithaeron but were found and brought up by a shepherd. Amphion became a great singer and musician, Zethus a hunter and herdsman. After rejoining their mother, they built and fortified Thebes, huge blocks of stone forming themselves into walls at the sound of Amphion's lyre. Amphion later married Niobe and killed himself after the loss of his wife and children.

amphioxus, plural AMPHIOXI, or AMPHIOXUSES, also called LANCELET, any of certain members of the invertebrate subphylum

Cephalochordata of the phylum Chordata. They are small marine animals found widely in the coastal waters of the warmer parts of the world and less commonly in temperate waters.

A brief treatment of amphioxi follows. For full treatment, see MACROPAEDIA: Chordates. Amphioxi are seldom more than 8 cm (3 inches) long, and in appearance they resemble small, slender fishes without eyes or definite heads. They are grouped in two genera—*Branchiostoma* (also called *Amphioxus*) and *Epigonichthyes* (also called *Asymmetron*)—with about two dozen species. The chordate features—the notochord (or stiffening rod), gill slits, and dorsal nerve cord—appear in both the larval and adult forms.

Amphioxi spend much of their time buried in gravel or mud on the ocean bottom, although they are able to swim. When feeding, they let the anterior part of the body project from the surface of the gravel so that they can filter food particles from water passing through their gill slits. At night they often swim about near the bottom. Burrowing is performed by rapid movements of the body, which is tapered at both ends and is covered by a sheath called the cuticle.

The animals swim by contracting the muscle blocks, or myotomes, that run from end to end on each side of the body. The blocks on each side are staggered, producing a side-to-side movement of the body when swimming. Amphioxi are not buoyant, and they sink

quickly when they stop swimming. A dorsal fin runs along the entire back, becomes a caudal fin around the tip of the tail, and then continues as a ventral fin; there are no paired fins.

The notochord runs through the body from tip to tip, providing a central support. A slight bulge distinguishes the anterior end of the nerve cord, but there is no brain. The blood flows forward along the ventral side and backward along the dorsal side, but there is no distinct heart.

The oral cavity of amphioxi is furnished with a hood whose edges are lined with cirri; these are fringelike structures that form a coarse filter to screen out particles too large to be consumed. Water is directed through the small mouth into the pharynx by the action of cilia on the gill slits. Food particles in the passing water are caught by the mucous lining of the gill basket and passed into the gut, where they are exposed to the action of enzymes. Unlike other chordates, amphioxi are capable of a digestive process called phagocytosis, in which food particles are enveloped by individual cells.

Above the pharynx is the excretory system made up of the nephridia, which opens into an excretory canal leading to the atrium. The endostyle corresponds to the thyroid in vertebrates, since it seems to produce iodinated, tyrosine molecules, which may function as regulatory substances, much like hormones, in amphioxi.

Amphiboles

name formula	colour	lustre	Mohs hardness	specific gravity	habit or form	fracture or cleavage	refractive indices	crystal system space group	remarks
actinolite $\text{Ca}_2(\text{Mg}, \text{Fe})_5[\text{Si}_6\text{O}_{22}(\text{OH}, \text{F})_2]$	colourless to gray; darkens with increased Fe through green to black	silky; oily	5-6	2.9-3.2	fibrous massive	one perfect cleavage of 56°	tremo ferro $a = 1.600-1.672$ $\beta = 1.614-1.686$ $\gamma = 1.627-1.693$	monoclinic C_2/m	tremolite is Mg end-member Mg:Fe>4:1; ferrotremolite is Fe end-member, Mg:Fe<1.4; actinolite is intermediate, 4:1>Mg:Fe>1:4
anthophyllite $(\text{Mg}, \text{Fe})_7[\text{Si}_6\text{O}_{22}(\text{OH}, \text{F})_2]$	white, gray, green, or various shades of brown	vitreous	5½-6	2.9-3.2	fibrous or lamellar masses; bladed and prismatic crystal aggregates	one perfect cleavage of 54°	antho gedr $a = 1.587-1.642$ $\beta = 1.602-1.655$ $\gamma = 1.613-1.661$	orthorhombic Pnma	forms solid solution series with gedrite in which Al partially replaces both Mg and Si
arfvedsonite $\text{Na}_{2.5}\text{Ca}_{0.5}(\text{Fe}^{+2}, \text{Mg}, \text{Fe}^{+3}\text{Al})_5[\text{Si}_{7.5}\text{Al}_{0.5}\text{O}_{22}(\text{OH}, \text{F})_2]$	dark bluish green to greenish black or black	vitreous	5-6	3-3.5	long prisms; prismatic aggregates	one perfect cleavage of 56°	ecker arfv $a = 1.612-1.700$ $\beta = 1.625-1.709$ $\gamma = 1.630-1.710$	monoclinic C_2/m	forms solid solution series with eckermannite in which Mg replaces Fe and which contains Li
basaltic hornblende $\text{Ca}_2(\text{Na}, \text{K})_{0.5-1.0}(\text{Mg}, \text{Fe}^{+2})_{3-2}(\text{Fe}^{+3}, \text{Al})_{2-3}[\text{Si}_6\text{Al}_2\text{O}_{22}(\text{O}, \text{OH}, \text{F})_2]$	brown to black	glassy	5-6	3.2-3.3	massive	one perfect cleavage of 56°	$a = 1.622-1.690$ $\beta = 1.672-1.730$ $\gamma = 1.680-1.760$	monoclinic C_2/m	
common hornblende $(\text{Ca}, \text{Na}, \text{K})_{2-3}(\text{Mg}, \text{Fe}^{+2}, \text{Fe}^{+3}, \text{Al})_5[\text{Si}_6(\text{Si}, \text{Al})_2\text{O}_{22}(\text{OH}, \text{F})_2]$	pale to dark green	glassy	5-6	3-3.4	massive	one good cleavage of 56°	$a = 1.615-1.705$ $\beta = 1.618-1.714$ $\gamma = 1.632-1.730$	monoclinic C_2/m	
cummingtonite $(\text{Mg}, \text{Fe})_7[\text{Si}_6\text{O}_{22}(\text{OH})_2]$	dark green; brown	silky	5-6	3.1-3.6	fibrous or lamellar massive	one good cleavage of 55°	cumm grun $a = 1.643-1.688$ $\beta = 1.658-1.711$ $\gamma = 1.663-1.731$	monoclinic C_2/m	forms solid solution series with grunerite in which Fe:Mg<7:3; natural cummingtonite contains at least 30% Fe
glaucophane $\text{Na}_2\text{Mg}_3\text{Al}_2[\text{Si}_6\text{O}_{22}(\text{OH}, \text{F})_2]$	gray or lavender-blue	vitreous	6	3.1-3.3	fibrous or columnar massive	one good cleavage of 58°	$a = 1.606-1.661$ $\beta = 1.622-1.667$ $\gamma = 1.627-1.670$	monoclinic C_2/m	forms solid solution series with riebeckite and magnesioriebeckite (see below), the intermediate members having physical properties between glaucophane and riebeckite
richterite $\text{Ca}_3\text{Na}_2(\text{Mg}, \text{Mn})_{10}\text{Si}_{16}\text{O}_{44}(\text{OH})_4$	brown, yellow, brownish red, pale to dark green	vitreous	5-6	3-3.4	elongated crystals	one perfect cleavage of 56°	$a = 1.605-1.685$ $\beta = 1.618-1.700$ $\gamma = 1.627-1.712$	monoclinic C_2/m	related to tremolite, but has Na replacing Ca
riebeckite $\text{Na}_3\text{Fe}^{+2}\text{Fe}^{+3}[\text{Si}_6\text{O}_{22}(\text{OH}, \text{F})_2]$	dark blue or black	vitreous	5	3-3.4	longitudinally striated prismatic crystals; fibrous massive	one good cleavage of 56°	magnes riebeck $a = 1.645-1.701$ $\beta = 1.662-1.711$ $\gamma = 1.668-1.717$	monoclinic C_2/m	forms solid solution series with magnesioriebeckite, in which Mg replaces Fe ⁺² , and with glaucophane, in which Mg replaces Fe ⁺² and Al replaces Fe ⁺³ (see above)

Amphioxus (*Branchiostoma*)

Walter Dawn

Male and female amphioxii are identical in outward appearance and differ internally only in the nature of the gonads, or reproductive glands, which form in rows on the wall of the atrial cavity. Breeding takes place several times a year in tropical regions but only once in temperate areas. Sacs containing eggs or sperm burst and discharge their contents into the water through the atriopore, an opening on the underside of the body. Fertilization takes place in the water, and after about two days larvae develop from the fertilized eggs. The larvae drift with ocean currents until they reach a certain size and metamorphose into adults. The animals then sink to the bottom, to live in the gravel, most commonly at depths of not more than 50 fathoms.

Amphioxii are useful in filtering the water, and in areas where they abound the water is usually clean. Along parts of the coast of China, they are so numerous that they constitute the basis of a fishing industry. No fossil has been found that can be definitely classified as an amphioxus, and classification is based wholly on study of living forms.

amphipod, any member of the invertebrate order Amphipoda (class Crustacea) inhabiting all parts of the sea, lakes, rivers, sand beaches, caves, and moist (warm) habitats on many tropical islands. Marine amphipods have been found at depths of more than 9,100 m (30,000 feet). Freshwater and marine beach species are commonly known as scuds; those that occupy sand beaches are called sand hoppers, or sand fleas (see sand flea). About 4,600 species have been described. Extraordinarily abundant in the rocky coastal regions of all seas and often exceeding densities of 10,000 per square m (1,000 per square foot), amphipods are often mistaken for tiny shrimp, which they resemble. They are important food for many fishes, invertebrates, penguins, shore birds, small cetaceans, and pinnipeds. Amphipods are also important as scavengers of carrion.

Body length varies from 1 to 140 mm (0.04 to 5.5 inches), but the amphipod of midlatitude regions is about 4 to 10 mm long (0.16 to 0.4 inch). Many amphipods are brightly coloured—red, pink, yellow, green, or blue. The body is usually compressed from side to side (*i.e.*, height is greater than width), thus in part facilitating rapid sliding movement through algal fronds (leaflike structures). Most amphipods are active swimmers, being propelled by three pairs of abdominal appendages. That they are also strong jumpers is best seen in sand fleas.

The antennae are long and hairy. As in the shrimp, the head and tail ends are often curved downward. The eyes are sessile (without a stalk). Some species with piercing and sucking mouthparts are rather strictly confined to sedentary positions on large, mostly nonmoving invertebrates, such as cnidarians

and sponges. One marine family (Cheluridae) chews wood and is obligatorily associated with the isopod *Limnoria*, another wood borer. Few gammarideans (suborder Gammaridea) are predatory; they are mostly scavengers and herbivores, many species burrowing into the soft mud of the sea bottom. Amphipod gills are partially protected by long coxae, which are ventral extensions of the basal leg segments.

The sexes are separate, males often being characterized by enlarged gnathopods (claws on the second thoracic segment) used to grasp females during copulation. The male presumably emits sperm, or spermatophores (balls of sperm), to fertilize the eggs of the female externally.

The number of eggs in a clutch varies from one to more than 250. The arrangement of gills provides a chamber for fertilized eggs, which are carried externally by the female and held in a cluster near the gills. The gammaridean egg cluster is probably kept fresh with water currents created by beating appendages called pleopods. Eggs hatch in 2 to 59 days, and the young may remain in the brood pouch for from 2 to 35 days. After six to nine molts over an interval of one to four months, sexual maturity is attained. A few cold-water species live at least a year, perhaps far longer.

The generic diversity of amphipods is apparently higher in cool waters than in warm ones. One enigma is the enormous diversity of species, more than 290 in the Siberian Lake Baikal. Fossilization of amphipods is

Amphipod (*Gammarus locusta*)

William H. Amos—Helen Wohlberg, Inc.

poor; only six genera have been recorded, the earliest of which, *Paleogammarus*, is found in Baltic amber of the Early Eocene epoch (57.8 to 52 million years ago); it closely resembles a recent genus, *Crangonyx*.

Amphipolis, ancient Greek city on the Strymon (Strimón) River about three miles from the Aegean Sea, in Macedonia. A strategic transportation centre, it controlled the bridge over the Strymon and the route from northern Greece to the Hellespont, including the western approach to the timber, gold, and silver of Mount Pangaeum in Thrace. Originally a Thracian town (Ennea Hodoi, "Nine Roads"), it was colonized by Athens in 436 BC. The Spartan Brasidas seized it in 424 and defeated the Athenian Cleon, who tried to recapture it in 422. It was officially returned to Athens by the Peace of Nicias (421) but actually remained independent, despite Athenian attempts to regain control (416 and 368–365). Philip II of Macedonia occupied it in 357, and it remained under Macedonian control until 168, when Rome made it a free city and also the headquarters of the Roman governor of Macedonia. Traces of ancient fortifications and a Roman aqueduct are on the city's site, which is occupied by the modern town of Amfípólis.

Amphissa, Modern Greek *ÁMFISSA*, agricultural centre, chief town of the *eparkhia* ("eparchy") of Parnassus (Parnassós), capital of the *nomós* (department) of Fokis (Phocis), central Greece, at the northwestern limit of the fertile, Krissaeen plain between the Gióna

Mountains and the Parnassus massif. The economy includes trade in wheat, livestock, and particularly olives grown on the Crisaeen plain. Bauxite is mined southeast of Amphissa and trucked to an aluminum-reduction plant at neighbouring Antikyra on an inlet of the Gulf of Corinth.

During the European Middle Ages, Itéa, the ancient Chaleion, supplanted the 6th-century-BC port of Cyrrha (Kírra), situated just southeast of Itéa. On Amphissa's acropolis sits a ruined Franco-Catalan fortress supported by ancient foundations. The town is the seat of a metropolitan bishop of the Orthodox Church of Greece.

Close to Delphi, ancient Amphissa was the capital of Ozolian (western) Locris. The ruined acropolis of the modern tiered town dates apparently from about the 5th century BC, or late Archaic period. The city provoked the Third Sacred War when it was denounced (339 BC) for the impiety of cultivating the sacred wooded plain of Crisa, still drained by the stream Pleistus. The following year it was destroyed by Philip II of Macedonia, who undertook the punitive mission on behalf of the Council of the Delphic Amphictyony (a league of Greek states), a task that also gave him an excuse to tighten his control on other Greek cities, leading to their permanent loss of independence after the Battle of Cheronaea (338 BC). The rebuilt city joined the Aetolian League, remaining a member until 167 BC, when it was forced to secede by Roman conquest. The 2nd-century-AD Greek traveler Pausanias reported that Amphissa had a temple to Athena with a very early statue of the goddess. Inscriptions concerning repairs on the city's aqueduct indicate that it remained active through the late Roman period.

Destroyed by the Bulgars about the 10th century, Amphissa was rebuilt by the Franks and became known as Sálona. It was held by the Catalans (1311–35), passing then to Count Alphonse Frederick of Aragon, whose family held it until its fall to the Turks in 1394. Amphissa became part of Greece when it won its independence from Turkey in 1829. Pop. (1991) 7,189.

amphitheatre, also spelled AMPHITHEATER, freestanding building of round or, more often, oval shape with a central area, the arena, and seats concentrically placed around it. The word is Greek, meaning "theatre with seats on all sides," but as an architectural form the amphitheatre is of Italic or Etrusco-Campanian origin and reflects the requirements of the specific forms of entertainment that these people cherished—*i.e.*, gladiatorial games and *venationes*, contests of beasts with one another, or men with beasts. Originally such games took place in the forum, and wooden stands were erected from time to time to accommodate the spectators. The earliest permanent extant amphitheatre is one at Pompeii (c. 80 BC), in which the arena is sunk below the natural level of the surrounding ground. It is built of stone 445 by 341 feet (136 by 104 m) and seated approximately 20,000 spectators.

The great Flavian Amphitheatre, or Colosseum, in Rome was erected by the emperors Vespasian and Titus (c. AD 70–82) on the site of the Golden House of Nero. The name Colosseum was applied to this structure some time after the 8th century because of its immense size and capacity, accommodating nearly 50,000 people.

Great Roman amphitheatres were also built at Verona and at ancient Capua (modern Santa Maria Capua Vetere), where the amphitheatre, built in the 1st century, is second in size to the Colosseum, measuring 560 by 460 feet (170 by 140 m), and 95 feet (30 m) high. Outside Italy, Roman amphitheatres were built at Nîmes and

Arles in France, Pula in Istria (Croatia), and Thysdrus (El Djem) in Africa. The arenas were about 200 to 300 feet (60 to 90 metres) long and about 115 to 200 feet (35 to 60 metres) wide. Fragmentary remains of more than 75 Roman amphitheatres have been found in widely scattered areas throughout the provinces of the Roman Empire. The best preserved in Britain is the Roman amphitheatre at Caerleon in Gwent.

In most of the Roman amphitheatres, an elaborate labyrinth was constructed below the arena. The passages, including the *media via* for scenery, spaces for elevators and machinery that lifted the animals and stage sets, and rooms for the gladiators, were ingeniously arranged to connect, by means of many trapdoors, with the arena above. Around this arena, and separated from it by a high wall topped by a metal screen, rose the spectator seats. These were divided, by passageways running around the amphitheatre, into several sections (*maeniana*). In the lowest section, or podium, the emperor and his retinue had a special box; on the opposite side of the amphitheatre, but still in the podium, the vestal virgins, consuls, praetors, ambassadors, priests, and other distinguished guests were seated; the rest of the first gallery contained senators and those of the equestrian rank. The second gallery was reserved for patricians, the third for plebeians, and the fourth, uppermost, gallery for women, who were seated in boxes. An awning (*velum*, or *velarium*) was manipulated by sailors to shelter the spectators from the sun. Each of these galleries was divided into wedge-shaped sections (*cunei*) by radial walks that led to the many exits (*vomitoria*).

In modern usage the word amphitheatre is sometimes used for a theatre or concert hall whose seats surround the central area, as, for example, the Albert Hall, London, and both the new and the old Madison Square Garden in New York City, or may refer to a stadium where athletic competitions are held.

Outdoor amphitheatres, both ancient and relatively recent (e.g., Chicago's Soldier Field), continue to be used for sports events and

Roman amphitheatre, Verona, Italy

Anderson-Alman from Art Resource

many other kinds of entertainment, although in the mid-20th century, the structure took the form of a vast, roofed stadium (*q.v.*).

Amphitherium, extinct genus of early mammals known as fossils from Middle Jurassic deposits (of 187 to 163 million years ago). *Amphitherium* is the earliest representative of the pantotheres, a group of early mammals that, it is believed, represents the stock that gave rise to all the higher mammals of later times. *Amphitherium* is known from a lower jaw found in Europe and is characterized by the large number and distinctive structure of its teeth.

Amphitrite, in Greek mythology, the goddess of the sea, wife of the god Poseidon, and one

Amphitrite and Poseidon in a chariot, drawn by Tritons, detail of a frieze from an altar in the Temple of Neptune, Rome, 40 bc

Graudon—Art Resource

of the 50 (or 100) daughters (the Nereids) of Nereus and Doris (the daughter of Oceanus). Poseidon chose Amphitrite from among her sisters as the Nereids performed a dance on the isle of Naxos. Refusing his offer of marriage, she fled to Atlas, from whom she was retrieved by a dolphin sent by Poseidon. Amphitrite then returned, becoming Poseidon's wife; he rewarded the dolphin by making it a constellation. In works of art Amphitrite was represented either enthroned beside Poseidon or driving with him in a chariot drawn by sea horses or other fabulous sea creatures.

Amphitryon, in Greek mythology, son of Alcaeus, king of Tiryns. Having accidentally killed his uncle Electryon, king of Mycenae, Amphitryon fled with Alceme, Electryon's daughter, to Thebes, where he was cleansed from the guilt by Creon, his maternal uncle, king of Thebes. Alceme refused to marry Amphitryon until he had avenged the death of her brothers, all of whom except one had fallen in battle against the Taphians. Creon offered his help if Amphitryon would rid him of the uncatchable Cadmeian vixen. Amphitryon

borrowed Cephalus' invincible Creton hound Laelaps, and Zeus changed both Laelaps and the vixen to stone. The Taphians, however, remained invincible until Comaetho, the king's daughter, out of love for Amphitryon, cut off her father's golden hair, the possession of which rendered him immortal. On Amphitryon's return to Thebes he married Alceme.

The more famous portion of the myth concerns Amphitryon's wife. When Amphitryon was once absent at war, Alceme became pregnant by Zeus, who, disguised as her husband, visited her; she became pregnant again by her real husband upon his return. Of these unions were born twin boys, of whom Iphi-

cles was the son of Amphitryon, Heracles the son of Zeus. A number of ancient dramatists presented the theme, notably Plautus, whose comedy *Amphitruo* still survives.

amphiuma, also called CONGO EEL, or CONGO SNAKE (*Amphiuma*), any of three species of North American salamanders belonging to the family Amphiumidae (order Urodela). Because they are long and slender and have inconspicuous legs, they are often mistaken for eels or snakes. The body is gray or brown and paler on the lower side. The usual habitat is swamps and drainage ditches.

Although there are both three-toed and one-toed species, the most widely distributed (Virginia to Louisiana) is *Amphiuma means*, which usually grows to 60–75 centimetres (24–30 inches) in length and has two toes on each foot. Amphiumas have strong jaws and sharp teeth and, unlike most salamanders, can bite viciously. Their diet consists chiefly of crayfish, clams, snails, and other small animals. The female is fertilized internally and lays from 40 to 150 eggs in a single clutch.

amphora, one of the principal vessel shapes in Greek pottery, a two-handled pot with a

Attic red-figure amphora by Euthymides showing revellers, c. 510 bc; in the Staatliche Antikensammlungen und Glyptothek, Munich

By courtesy of the Staatliche Antikensammlungen und Glyptothek, Munich

neck narrower than the body. There are two types of amphora: the neck amphora, in which the neck meets the body at a sharp angle; and the one-piece amphora, in which the neck and body form a continuous curve. The first is common from the Geometric period (c. 900 bc) to the decline of Greek pottery; the second appeared in the 7th century bc. The height of amphorae varies from large Geometric vases of 5 feet (1.5 metres) to examples of 12 inches (30 centimetres) or even smaller (the smallest are called *amphoriskoi*). The average normal height is about 18 inches (45 centimetres). Amphorae, which survive in great numbers, were used as storage and transport vessels for olives, cereal, oil, and wine (the wine amphora was a standard Attic measure of about 41 quarts [39 litres]) and, in outsize form, for funerals and as grave markers. Wide-mouthed, painted amphorae were used as decanters and were given as prizes.

The neck amphora, prefigured in Mycenaean (14th-century-bc) pottery and remodelled as a main shape in the Protogeometric style (1000–c. 900 bc), has about 12 distinct shape variations, determined as much by utilitarian as by aesthetic considerations. Noteworthy are the Nolan type (from Nola, Italy), some of which had triple handles popular in red-figure pottery; the Panathenaic amphora, painted in black-figure and presented as a prize (filled

with olive oil and having the inscription "I am one of the prizes from Athens") at the Panathenaic Festivals from the 6th to the 2nd century BC; and the *loutrophoros*, slender-bodied, with a tall neck and flaring mouth, used from the 6th century for ritual purposes at weddings and funerals. The one-piece amphora maintained a more consistent shape, with cylindrical handles, flaring lip, echinus foot, and amply curved belly. Amphorae, such as wine containers, continued to be made in profusion during the Roman Empire.

ampicillin, semisynthetic penicillin, one of the first such antibiotics developed. It is created by attaching acid radicals to the central structure of 6-aminopenicillanic acid. Similar in action to penicillin G—the most widely used natural penicillin—ampicillin (or alpha-aminobenzylpenicillin) is more stable in stomach acids and therefore may be given orally; it is also more active against certain strains of bacteria.

Because ampicillin is easy to administer, it is a popular penicillin antibiotic. It is used regularly to treat common urinary-tract infections, some respiratory infections, and bacterial meningitis in children, although many strains of *Hemophilus influenzae* (the most common cause of bacterial meningitis) are now resistant to ampicillin, and it commonly is used along with other drugs.

The potential side effects of ampicillin are similar to those of other penicillins—*i.e.*, chiefly allergic reactions ranging from skin rashes and hives to life-threatening anaphylactic shock (very rare). People who are allergic to other drugs in this family are also likely to react to ampicillin. The incidence of skin rashes is higher with ampicillin than with other penicillins, a factor that suggests a possible toxic reaction, as well as a truly allergic response.

amplifier, in electronics, device that responds to a small input signal (voltage, current, or power) and delivers a larger output signal that contains the essential waveform features of the input signal. Amplifiers of various types are widely used in such electronic equipment as radio and television receivers, high-fidelity audio equipment, and computers. Amplifying action can be provided by electromechanical devices (*e.g.*, transformers and generators) and vacuum tubes, but most electronic systems now employ solid-state microcircuits as amplifiers. Such an integrated circuit consists of many thousands of transistors and related devices on a single tiny silicon chip.

A single amplifier is usually insufficient to raise the output to the desired level. In such cases the output of the first amplifier is fed into a second, whose output is fed to a third, and so on, until the output level is satisfactory. The result is cascade, or multistage amplification. Long-distance telephone, radio, television, electronic control and measuring instruments, radar, and countless other devices all depend on this basic process of amplification. The overall amplification of a multistage amplifier is the product of the gains of the individual stages.

There are various schemes for the coupling of cascading electronic amplifiers, depending upon the nature of the signal involved in the amplification process. Solid-state microcircuits have generally proved more advantageous than vacuum-tube circuits for the direct coupling of successive amplifier stages. Transformers can be used for coupling, but they are bulky and expensive.

An electronic amplifier can be designed to produce a magnified output signal identical in every respect to the input signal. This is linear operation. If the output is altered in shape after passing through the amplifier, amplitude distortion exists. If the amplifier does not amplify equally at all frequencies, the result is called frequency distortion, or discrimination

(as in emphasizing bass or treble sounds in music recordings).

When the power required from the output of the amplifier is so large as to preclude the use of electronic devices, dynamoelectric and magnetic amplifiers find wide application.

amplitude, in physics, the maximum displacement or distance moved by a point on a vibrating body or wave measured from its equilibrium position. It is equal to one-half the length of the vibration path. The amplitude of a pendulum is thus one-half the distance that the bob traverses in moving from one side to the other. Waves are generated by vibrating sources, their amplitude being proportional to the amplitude of the source.

For a transverse wave, such as the wave on a plucked string, amplitude is measured by the maximum displacement of any point on the string from its position when the string is at rest. For a longitudinal wave, such as a sound wave, amplitude is measured by the maximum displacement of a particle from its position of equilibrium. When the amplitude of a wave steadily decreases because its energy is being lost, it is said to be damped.

amplitude modulation (AM), variation of the amplitude of a carrier wave (commonly a radio wave) in accordance with the characteristics of a signal, such as a vocal or musical sound composed of audio-frequency waves. *See* modulation.

Amphill, town ("parish"), county of Bedfordshire, Eng., 8 miles (13 km) south-southwest of Bedford. The Church of St. Andrew contains a monument to Richard Nicolls (1624–72), the first English governor of New York. Amphill Park, with its ancient oaks, marks the site of the castle where Catherine of Aragon was forced to reside, pending her divorce from Henry VIII. The current house on the site was built in 1694. Amphill's interests are market gardening and farming. Pop. (1991) 6,230.

Amphill (of Amphill), Odo William Leopold Russell, 1st Baron (b. Feb. 20, 1829, Florence, Italy—d. Aug. 25, 1884, Potsdam, Ger.), British diplomat, the first British ambassador to the German Empire (1871–84).

A member of a prominent family, Russell as a youth became fluent in French, German, and Italian through tutoring and wide travel and also acquired the social gifts for a diplomatic career. He served in a variety of posts in Vienna, Paris, Constantinople, Washington, Florence, Naples, and finally Rome, where he remained 12 years (1858–70) in the official legation and, additionally, was an unofficial British representative to the Vatican, putting up some resistance to the idea of papal infallibility. He was then made ambassador to Berlin, where he attempted to remain on good terms with Otto von Bismarck, though he was aware of the chancellor's unscrupulousness and firmly withstood his deceptions. He was a plenipotentiary at the Congress of Berlin, working strongly behind the scenes (1878) and was afterward rewarded with a knighthood (1879) and a peerage (1881).

ampulla, plural AMPULLAE, a small narrow-necked, round-bodied vase for holding liquids, especially oil and perfumes. It was used in the ancient Mediterranean for toilet purposes and for anointing the bodies of the dead, being then buried with them. In early medieval times in Europe, ampullae were used in anointing kings. Both the name and the function of the ampulla have survived in Western Christianity, where it still designates the vessel containing the oil (chrism) consecrated by the bishop for ritual uses, especially in the sacraments of confirmation, orders, and extreme unction. It is used in the British coronation ceremony and is cited repeatedly by name in

the coronation service; the ampulla of the regalia of the United Kingdom takes the form of a golden eagle with outspread wings. Perhaps the most celebrated ampulla in history was that known as *la sainte ampoule* ("the holy ampulla"), at Reims, from which the kings of France were anointed (legend said that it was brought from heaven by a dove for the coronation of Clovis); this ampulla was destroyed during the French Revolution.

amputation, in medicine, removal of any part of the body. Commonly the term is restricted to mean surgical removal of a part of or an entire limb, either upper or lower extremity. The reasons for surgical amputation in general are injury, infection, tumour, diabetes, or insufficient blood supply. Persons born without a limb or limbs are said to have suffered congenital amputation. Surgical amputation may be a lifesaving measure for injured persons suffering from both loss of blood and infection; for persons with diabetic or arteriosclerotic gangrene, in whom amputation may be the only method of preventing spread of the gangrene; and for persons suffering from malignant tumours of soft tissue or bone.

Modern reconstructive surgery makes possible the rehabilitation of many badly damaged limbs without amputation, and experience gained in World War II of early and thorough treatment of the severely injured, particularly through the use of blood and plasma, has saved many extremities. Furthermore, modern prostheses (artificial parts), particularly for amputations in the lower extremity, have reduced the handicap for the amputee. The congenital amputee seldom requires any corrective surgery but is helped by prosthetic replacement. There is no definitely known causative factor for congenital amputation, but it probably is not a hereditary deformity.

'Amr ibn al-'Āṣ (d. 663, Al-Fuṣṭāṭ, Egypt), the Arab conqueror of Egypt.

A wealthy member of the Banū Sahn clan of the important tribe of Quraysh, 'Amr accepted Islām in 629–630. Sent to Oman, in southeastern Arabia, by the Prophet Muḥammad, he successfully completed his first mission by converting its rulers to Islām. As the leader of one of the three military forces sent to Palestine by the caliph Abū Bakr, he took part in the battles of Ajnādayn (634) and the Yarmūk River (636) and was responsible for the Muslim conquest of southwestern Palestine. He achieved lasting fame, however, for his conquest of Egypt—a campaign that, according to some sources, he undertook on his own initiative. After defeating large Byzantine forces at Heliopolis (now a suburb of Cairo) in 640 and Babylon (a Byzantine town on the site of the present Old Cairo) in 641, he entered the capital, Alexandria, in 642.

A successful general, 'Amr was also a capable government administrator and an astute politician. In Egypt he organized the system of taxation and the administration of justice and founded the garrison city of Al-Fuṣṭāṭ adjacent to Babylon, where he built a mosque (still standing) bearing his name. At the Battle of Ṣiffin (657), fought to decide the succession to the caliphate, he sided with Mu'āwiyah I, governor of Syria, against 'Alī, the fourth caliph of Islām. In the ensuing arbitration, he faithfully represented Mu'āwiyah, who rewarded him with the governorship of Egypt at the advent of the Umayyad caliphate (named for the Banū Umayyah clan of Mu'āwiyah) in 661.

'Amr ibn al-'Āṣ, Mosque of, earliest Islāmic building in Egypt, erected in 641 by 'Amr ibn al-'Āṣ, the leader of an invading Arab army. The mosque was built in Al-Fuṣṭāṭ, a city that

grew out of an Arab army encampment on the site of present-day Cairo.

Though originally a modest structure, it was destroyed and restored so often that it is impossible to know the appearance of the first building. The Umayyad 'Abd al-'Aziz ibn Marwan demolished the mosque and rebuilt it, probably following closely the original dimensions, in 698. In 827 the 'Abbāsids rebuilt it, doubling its size. The mosque was restored by Saladin in 1172 after the city of al-Fuṣṭāṭ was burned by crusaders. After periodic cycles of ruin and restoration, the mosque was left to decay with the coming of Napoleon Bonaparte's troops to Cairo in 1798. The present mosque is a 19th-century reconstruction that still preserves design elements and ornamental work from various periods of the building's history.

'Amr ibn Kulthūm (fl. 6th century), pre-Islāmic Arab poet whose *qaṣīdah* ("ode") is one of the seven that comprise the celebrated anthology of pre-Islāmic verse *al-Mu'allaqāt*.

Little is known of his life; he became chief of the tribe of Taghlib in Mesopotamia at an early age and according to tradition killed 'Amr ibn Hind, the Arab king of al-Ḥīrah, c. 568.

'Amr ibn Kulthūm lived to a very advanced age, highly respected for his noble character, for a poem, allegedly his, praising a Taghlib victory over the Bakr tribe, and for his successfully independent stance against the Lakhmid kings of al-Ḥīrah. 'Amr's *qaṣīdah*, as it appears in *al-Mu'allaqāt*, was probably altered by a later poet. It violently attacks 'Amr ibn Hind for an insult addressed to the poet's mother.

Amram bar Sheshna (d. 875?), head of the Talmudic academy at Sura, Babylonia, traditionally regarded as the first Jewish authority to write a complete domestic and synagogal liturgy for the year, the *Siddur Rav Amram* ("Order of Prayers of Rabbi Amram"). Amram's work, forerunner in this field of those of Sa'adia ben Joseph and Maimonides, laid the foundations for the liturgies of both the Sephardim (Spanish Jews) and Ashkenazim (Germanic Jews). In addition to the prayers, his liturgy included a related Talmudic commentary. Surviving in manuscript form, it was first published (in two parts) in Warsaw in 1865. Neither the first part, composed of the main body of prayers, nor the second, consisting of propitiatory prayers and liturgical poems for the month of Elul (August–September), the New Year, and the Day of Atonement, can be definitely attributed to Amram, and it is obvious that many of the devotions and interpolations are by other hands.

Amram also composed numerous responsa (replies to inquiries about Jewish Law), which, touching upon such subjects as dietary restrictions and regulations for sabbaths and holidays, reveal much of the Jewish Law and custom of his time.

Amratian culture, also called NAQĀDAH I CULTURE, Egyptian predynastic cultural phase, centred in Upper Egypt, its type-site being

Amratian tools and utensils

al-'Amīrah near Abydos in Qīnā *muḥāfaẓah* (governorate). Numerous sites, dating to about 3600 BC, have been excavated and reveal an agricultural way of life similar to that of the preceding Badarian culture, but with advanced skills and techniques, including mud-brick structures in fair-sized towns. Pottery characteristic of this period includes black-topped red ware and a dark-red burnished ware, occasionally decorated in white slip with bold linear designs—human or animal figures; on an Amratian shard excavated at Naqādah the earliest known representation of the pharaonic red crown is drawn. Other important remains include disk-shaped maceheads, slate cosmetic palettes, well-made stone vases and ivory carvings, and numerous figurines of various materials.

Amrāvati, also called AMRAOTI, town, administrative headquarters of Amrāvati district, Mahārāshtra state, western India, in the Be-rār region. The town occupies an important position near passes through the hills that separate the cotton-growing regions of the Pūrna Basin (west) and the Wardha Basin (east). A growing industrial centre, it is expanding toward nearby Badnera; its cotton mills supply Bombay, Calcutta, and Ahmadābād. The town houses seven colleges affiliated with the University of Nāgpur.

Amrāvati district occupies an area of 4,714 sq mi (12,210 sq km). The Melghāt Range forms the northern boundary with Madhya Pradesh state and contains the popular resort town of Chikalda (3,900 ft [1,200 m]). The broad alluvial basin of the Pūrna River in the south is one of India's principal cotton-growing areas. The district's towns are primarily agricultural markets, and its industry is mainly cotton ginning and pressing. The chief industrial centres are Amrāvati town and Badnera. Pop. (1991) town, 421,576; district, 2,200,000.

Amreli, formerly AMARAVALLI, town, administrative headquarters of Amreli district, southwestern Gujarāt state, west central India, on the Kāthiāwār Peninsula, southwest of Ahmadābād. Primarily a commercial centre, its industries include *khādī* (coarse cotton cloth) manufacture, tanning, silverworking, and cotton ginning. Amreli is served by a railway and an airfield.

Amreli district occupies an area of 2,610 sq mi (6,760 sq km). Organized in 1959, it is composed of the Kāthiāwār possessions of former Baroda princely state (acceded to India in 1949); Gogho *mahāl* (subdivision), formerly in Ahmadābād district; and *mahāls* from adjacent districts. Chief crops of the district are millet, peanuts (groundnuts), cotton, wheat, and pulses. Pop. (1991) town, 67,800; district, 1,252,589.

'Amri (Israelite king): see Omri.

Amritsar, city, administrative headquarters of Amritsar district, Punjab state, northwestern India, on the Pakistani border, the largest city in the state. A major commercial, cultural, and transportation centre, it lies approximately 30 mi (50 km) from the border. Amritsar was founded in 1577 by Rām Dās, fourth Gurū of the Sikhs, around a sacred tank, or pool, called Amrita Saras, from which the city's name is derived. A temple was erected on an island in the tank's centre; after its copper dome was covered with goldfoil, it was named the Hari-mandir, or Golden Temple. Amritsar became the centre of the Sikh faith. As the centre of growing Sikh power, it experienced a corresponding increase in trade. It was annexed to British India in 1849. The Amritsar Massacre, in which government troops fired on a political gathering and killed 379 and wounded more, occurred at a park, Jallianwālla Bāgh, in the city on April 13, 1919; the site is now a national monument. Another violent political clash took place in Amritsar in 1984, when troops of the Indian army attacked hundreds

of Sikh separatists who had taken up positions in and heavily fortified the Golden Temple. Conflicting reports indicated that between 450 and 1,200 persons were killed.

Headquarters of the Organization for the Management of the Sikh Temples at Amritsar, Punjab, India

Milt and Joan Mann—CAMERAMANN INTERNATIONAL

Amritsar's varied industries include textiles, food milling and processing, silk weaving, tanning, canning, and manufacturing. The city lies on the main highway from Delhi to Lahore, Pak., and is a major rail hub. An airport is nearby. Besides the Medical College, dental, arts, and technical colleges are located in Amritsar; and Khalsa College (established 1899) is just outside.

Amritsar district, 1,964 sq mi (5,088 sq km) in area, is an almost level plain drained by the Rāvi and Beās rivers. Because of the fairly dry climate the district's agriculture depends on irrigation, chiefly from the Upper Bāri Doāb Canal system; wheat, cotton, pulses, and corn (maize) are the biggest crops. Pop. (1991) city, 708,835; district, 2,503,165.

Amritsar, Massacre of (April 13, 1919), incident in which British troops fired on a crowd of Indian protesters, killing a large number. It left a permanent scar on Indo-British relations and was the prelude to Mahatma Gandhi's Non-cooperation Movement of 1920–22.

In 1919 the British government of India enacted the Rowlatt Acts, extending its World War I emergency powers to combat subversive activities. At Amritsar, Punjab (Pañjāb) district, about 10,000 demonstrators unlawfully protesting these measures confronted troops commanded by Brig. Gen. Reginald E.H. Dyer in an open space known as the Jallianwālla Bāgh, which had only one exit. The troops fired on the crowd, killing an estimated 379 and wounding about 1,200, according to one official report. The shooting was followed by the proclamation of martial law, public floggings, and other humiliations. The Hunter Commission condemned General Dyer (1920), but the House of Lords praised his action, and a fund was raised in his honour.

Amritsar, Treaty of (April 25, 1809), pact concluded between Charles T. Metcalfe, representing the British East India Company, and

Ranjit Singh, head of the Sikh kingdom of Punjab (Pañjāb); it settled Indo-Sikh relations for a generation. The immediate occasion was the French threat to northwestern India, following Napoleon's Treaty of Tilsit with Russia (1807) and Ranjit's attempt to bring the Cis-Sutlej states under his control. The British wanted a defensive treaty against the French and control of Punjab to the Sutlej River. Although this was not a defensive treaty, it did fix the frontier with Ranjit broadly along the line of the Sutlej River.

Metcalf's mission gave Ranjit much respect for the company's disciplined troops and determination never to cross swords with them. His further conquests were to the west and north.

Amroha, town, northwestern Uttar Pradesh state, northern India, west-northwest of Morādābād town, on the Sot River. A marketplace for agricultural produce, its chief industries are handloom weaving, pottery making, and sugar milling. Colleges of Āgra University are located there, as is the shrine of Sheikh Saddu, a Muslim saint. Amroha is connected by rail with Morādābād and Delhi. Pop. (1991) 137,061.

Amrouche, Jean (b. Feb. 7, 1906, Ighil Ali, Alg.—d. April 16, 1962, Paris), foremost poet of the earliest generation of French-speaking North African writers.

Amrouche was born into one of the few Roman Catholic families in the Petite Kabylie mountains but immigrated with his family to Tunisia when still quite young. He completed his studies in Tunis and Paris.

As a young man, Amrouche published *Cendres* (1934; "Cinders") and *Étoile secrète* (1937; "Secret Star"), the most significant volumes of Algerian poetry ever written in French. Taking inspiration from his Berber roots as well as from modern European post-Symbolism, Amrouche testifies to the purity of his origins, evoking the quest for a lost homeland and the sense of ancestral nobility. A lyricist of the first order, he clothed his verse, written in the borrowed language of the colonial rulers, in an eloquent and fluid beauty. Later works included a translation into French of Berber lyrics and an essay, "L'Éternel Jugurtha" (1946), that stands as the definitive statement on the Maghribian identity torn by the complexes of acculturation and alienation. Amrouche taught and produced a radio show in which he interviewed writers. In his later years he broadcast appeals for the Algerian cause to the French people.

Amrouche, Marguerite Taos, original name MARIE-LOUISE AMROUCHE, also called MARGUERITE TAOS (b. March 4, 1913, Tunis—d. April 2, 1976, Saint-Michel-l'Observatoire, Fr.), Kabyle singer and writer.

Amrouche was the daughter of Fadhma Aïth Mansour Amrouche; she was the only sister in a family of six sons and was born after the family had moved to Tunisia to escape persecution after their conversion to Roman Catholicism. Despite this exile, both she and her brother Jean returned to Algeria for extended visits. Through her mother's influence she became interested in the rich oral traditions of the Kabyle Berber people. In 1934 she obtained her *brevet supérieur* in Tunis, and in the following year she went to France for studies at the École Normale at Sèvres. She worked briefly as an assistant at a boarding school in Radès. Starting in 1936, in collaboration with Jean and her mother, Amrouche collected and began to interpret Kabyle songs. In 1937–38 she presented her repertoire in Paris and in Munich. At the Congrès de Chant de Fès in 1939 she received a scholarship to study at the

Casa Velasquez in Spain, where she researched the ties between Berber and Spanish popular songs.

Amrouche's first novel, *Jacinthe noire* (1947; "Black Hyacinth"), recounts the story of an "uncivilized" young Tunisian girl who is sent to a French pension for studies. Differences in life-style, attitudes, and experiences set her apart, and exile, prejudice, and rupture are themes of the novel, which is one of the earliest ever published in French by a North African woman writer. A second novel, *Rue des tambourins* (1960; "Street of the Tabors"), describes a sense of marginality and owes a great deal to its author's recollections of her childhood in Tunis.

Le Grain magique (1966; "The Magic Grain")—a collection of legends, short stories, songs, poems, and proverbs from the Kabyle, translated by her from Berber into French—is perhaps her best-known work. She recorded several phonograph albums and produced a number of programs for French radio and television, including *Chants sauvés de l'oubli* ("Songs Saved from Oblivion") and *Hommage au chant profond* ("Homage to a Profound Song").

Amsdorf, Nikolaus von (b. Dec. 3, 1483, Torgau, Saxony [Germany]—d. May 14, 1565, Eisenach), Protestant Reformer and major supporter of Martin Luther.

Educated at Leipzig and then at Wittenberg, where he became a theology professor in 1511, Amsdorf attended the Leipzig Debate with

Amsdorf, lithograph 1820, after a 16th-century engraving
Kester Lichtbild Archiv

Luther in 1519 and the Diet of Worms two years later, where he participated in the plan to protect Luther from his detractors by pretending to kidnap him while actually lodging him secretly in Wartburg, a castle near Eisenach. Amsdorf subsequently aided the Reformation at Magdeburg (1524), Goslar (1531), Einbeck (1534), and Schmalkalden (1537). When Luther, in 1539, supported the intended bigamous marriage of Philip, landgrave of Hesse, Amsdorf temporarily opposed him but was made bishop of Naumburg by Luther and by John Frederick I, elector of Saxony, in 1541.

As an Evangelical holding a bishopric, Amsdorf found his position difficult but remained under Luther's persuasion until it was necessary to yield to the Roman Catholic bishop Julius von Pflug in 1547. Exiled to Magdeburg, Amsdorf superintended the Jena edition of Luther's works. Continuing to fight for the purity of Luther's doctrine, he opposed the more liberal views of Philipp Melancthon and other Reformers. In particular he emphasized that salvation could come only to men of faith and that their efforts to perform good works might even be self-defeating. Among Amsdorf's extant writings are numerous letters and varied short works.

Amstelveen, *gemeente* (commune), in Noordholland *provincie*, western Netherlands, near the Amstel River. Amstelveen (meaning "peat bog on the Amstel") was formerly a village in the municipality of Nieuwer-Amstel. A

residential suburb of Amsterdam, it is a water-sports centre with some agriculture and light industry. Schiphol international airport is nearby to the west. Pop. (1999 est.) 77,737.

Amsterdam, city and port, western Netherlands, located at the head of Lake IJssel, a former inlet of the North Sea. Renowned for its scenic cityscape and its culture of tolerance, Amsterdam occupies some 90 islands lining canals and connected by bridges. It is the nominal capital of The Netherlands, but not its seat of government (which is The Hague).

A brief treatment of Amsterdam follows. For full treatment (including a map), see MACROPAEDIA: Amsterdam.

Amsterdam is situated on the IJ, an inland arm of the former Zuiderzee, now Lake IJssel, and is connected by canal with the North Sea. The canalized Amstel River flows through the city toward the IJ. To protect themselves from floods, the early inhabitants built dikes on both sides of the Amstel and in 1270 built a dam between these dikes, the Amstel-dam. By the mid-17th century Amsterdam had become the financial centre of the world, and it remains the main financial and commercial centre of The Netherlands.

The medieval portion of Amsterdam, enclosed by the semicircular Singel ("Canal," or "Moat"), lies on both sides of the Amstel at the city's centre. There are many reminders of the city's glorious past—the gabled houses, the almshouses, the richly decorated cornices, the towers and churches, and the music of carillons and barrel organs. Among the ancient buildings still preserved are the 13th-century Old Church and the 15th-century New Church. Other notable buildings include the Royal Palace, in classical Palladian style; the Mint Tower; and the West Church (1631), where Rembrandt van Rijn is buried. The former Jewish quarter, in the east of the old town, is the site of the Portuguese Synagogue (1670) and Rembrandt's house, now a museum. The old town's three main squares are the Dam, Leidseplein, and Rembrandtsplein. Notable buildings constructed since the late 19th century include the Rijksmuseum ("State Museum"; 1876–85), known for its collection of 17th-century art; the Concertgebouw ("Concert Hall"); and the Olympic Stadium (1928).

After World War II, modernist public housing estates, such as Sloterveer, Buitenveldert and Bijlmermeer, arose on Amsterdam's periphery. Since the 1970s, the trend has shifted toward low-rise projects that mix public and private housing. Although the area of the city of Amsterdam has tripled since 1945, the population has not significantly increased.

Amsterdam has been important economically since the 17th century, when it was Europe's banking centre. The Dutch East India Company was also founded there during the 17th century and laid the basis for modern stock trading; the Amsterdam Stock Exchange is considered the world's oldest.

Amsterdam has played an important role in wholesale trade since the 14th century. Tourism also plays a major role in the city's economy. By the late 1960s the harbour mouth at IJmuiden (about 15 miles [24 km] northwest of the city) had been modernized. There is a major international airport at Schiphol, about 5 miles (8 km) from the city.

Amsterdam is perhaps most noted as a centre for culture and the arts. It is home to some 40 museums besides the Rijksmuseum, including the Van Gogh Museum and the Anne Frank House, as well as numerous art galleries. Area city, 64 square miles (165 square km); metropolitan area, 245 square miles (635 square km). Pop. (1999 est.) city, 727,053; metropolitan area, 1,121,303.

Amsterdam, city, Montgomery county, eastern New York, U.S. It lies along the Mohawk River, 16 miles (26 km) northwest of Schenectady. Settled by Albert Veeder in 1783, it was known as Veedersburg until renamed for Amsterdam, Neth., in 1804. Its location on the Mohawk Trail, the completion of the Erie Canal in 1825 (improved as the New York State Barge Canal), and the arrival of the railroad (1836) stimulated its development. By 1838 textile mills had been set up along Chucatanunda Creek, a tributary of the Mohawk.

The city's once-dominant carpet and textile industries have to some extent given way to diversified manufactures, notably electronic equipment and toys. Fort Johnson (1749), the home of Sir William Johnson, and nearby Guy Park, a stone mansion built in 1773 for Guy Johnson, deputy of Indian Affairs, are now state historic sites. The National Shrine of the North American Martyrs (René Goupil, Isaac Jogues, and Jean Lalande, who were massacred by Mohawk Indians) is at Auriesville, 6 miles (10 km) west. The Schoharie Crossing State Historic Site, 5 miles (8 km) west, includes locks and a remarkable seven-arched aqueduct (1842) that was built to carry the water of the Erie Canal over the separate water of a transverse stream. Inc. village, 1830; city, 1885. Pop. (1994 est.) 20,065.

Amsterdam Cabinet, Master of the (late Gothic painter and engraver): *see* Housebook, Master of the.

Amsterdam-Rhine Canal, Dutch AMSTERDAM-RIJNKANAAL, waterway connecting the port of Amsterdam with the Lek River (via Utrecht) and the Waal River (at Tiel) in The Netherlands. Inaugurated in 1952, it has a total length of 45 miles (72 km) and four locks. It is considered to be the most heavily used canal in western Europe, and it handles vessels of up to 4,300 tons' displacement. The canal's minimum depth is 18 feet (5.5 m).

Amstetten, town, Niederösterreich *Bundesland* (federal state), northeastern Austria. It is situated near the Ybbs River, northeast of Steyr. Recorded in 996 as a possession of the bishops of Passau, it was fortified and granted market rights when it passed to the Habsburgs in 1276. It achieved town status in 1897. The 14th-century parish church in the town incorporates an earlier Romanesque basilica. Amstetten has metal, wood, and construction industries and manufactures baked goods, glass, clothing, and chemicals. Pop. (1991) 21,972.

Amtrak, formally NATIONAL RAILROAD PASSENGER CORPORATION, federally supported corporation that operates nearly all intercity passenger trains in the United States. It was established by Congress in 1970 and assumed control of passenger service from the nation's private rail companies the following year. Virtually all railways, with the exception of a small handful, signed contracts with Amtrak. The corporation pays the railroads to run their passenger trains and also compensates them for the use of certain facilities, including tracks and terminals. It bears all administrative costs, such as those incurred for the purchase of new equipment, and manages scheduling, route planning, and the sale of tickets.

Amtrak was founded to relieve American railroads of the financial burden of providing passenger service and to improve the quality of that service. Since about the early 1960s, the railroads had lost millions of dollars annually on their passenger lines as a result of a steady decline in their ridership and increases in their operating costs. In order to avert further losses, many of the companies dropped their unprofitable routes. In 1950 there were approximately 9,000 passenger trains in ser-

vice, which carried just under 50 percent of all intercity traffic. By 1970, however, there were only about 450 trains still in operation, with a total share of the passenger traffic amounting to a mere 7 percent.

The creation of Amtrak marked the first time that rail passenger service received any form of direct financial assistance from the U.S. government (although land grants had been given railroads to spur completion of a transcontinental line some 109 years earlier). Congress provided Amtrak with an initial grant of \$40,000,000 and authorized an additional \$100,000,000 in government-guaranteed loans. In the late 20th century, Amtrak received several million dollars in federal funds annually to cover operating losses. Although the corporation derived income from ticket sales and from its mail-carrying service, its revenues were not enough to offset its expenditures. Facing a decline in federal funding in the mid-1990s, Amtrak reorganized its corporate structure, initiated changes in service, and sought alternative financing, including subsidies from state governments.

Amu Darya, Tajik DARYOI AMU, Turkmen AMYDERYA, Uzbek AMUDARYO, ancient name OXUS RIVER, one of the longest rivers of Central Asia. It is formed by the confluence of the Vakhsh and Panj (Pyandzh) rivers and flows west-northwest to its mouth on the southern shore of the Aral Sea. In its upper course the Amu Darya forms part of the border between Afghanistan (south) and Tajikistan, Uzbekistan, and Turkmenistan (north). In its lower course the river forms part of the boundary between Uzbekistan (northeast) and Turkmenistan (southwest). The Amu Darya has a length of 879 miles (1,415 km), but its length is 1,578 miles (2,540 km) if measured from the remotest sources of its headstream, the Panj River in the Pamirs.

The river was traditionally known to the Western world from Greek and Roman times as the Oxus and was called Jayhūn by the Arabs. It allegedly derives its present name from the city of Amul, which is said to have occupied the site of modern Chärjew in Turkmenistan.

The Amu Darya's basin extends for 600 miles (950 km) from north to south and for more than 900 miles (1,450 km) from east to west. It borders on the Syr Darya basin in the north, on the Tarim Basin in the east, and on the Indus and Helmand river basins in the south. Of the basin's total area of 179,700 square miles (465,500 square km), only half belongs to the regions whence the river is fed—that is to say, to the mountain ranges to the east.

Hydrologically, the Amu Darya's basin consists of two units: a mountainous zone of nourishment and a lowland zone of depletion. The Amu Darya's headwaters rise in the mountains of Tajikistan and Afghanistan, among the permanent snows and glaciers of the Pamirs (with the adjacent Alay Range to the northwest) and the Hindu Kush, where elevations range from 16,400 to 23,000 feet (5,000 to 7,000 m). The river's two principal upstream extensions, the Panj (including the Pamir and other source streams) and Vakhsh rivers, follow a westerly course. The river receives the name Amu Darya only below the confluence of the Panj with the Vakhsh. Not far below this junction the Amu Darya is joined by three additional tributaries: from the left (south) by the Qondūz River and from the right (north) by the Kofarnihon (Kafirnigan) and Surkhan rivers. After leaving the highland zone, the river veers to the northwest to cross the arid Turan Plain, where it forms the boundary between the Karakum Desert to the southwest and the Kyzylkum Desert to the northeast. There the Amu Darya loses much of its water to irrigation, evaporation, and seepage.

In its once-extensive delta the Amu Darya branched into a number of tributaries that emptied into the Aral Sea. A massive diversion of water from the main stream and from its tributaries was undertaken by the Soviet regime in the decades after World War II in order to provide irrigation for cotton and other crops grown in the river's basin. The main section of the Karakum Canal was completed in the 1960s to carry water from the Amu Darya at Kerki, Turkmenistan, westward to Mary and Ashgabat. The diversion of its waters for irrigation increased the Amu Darya's level of salinity and left less water to enter the Aral Sea, which consequently began shrinking. By the 1990s the discharge of the Amu Darya into the Aral Sea stopped for one to three months in most years. Most of the lakes and bogs in the Amu Darya delta dried up, and its wetlands shrank to only a tiny percentage of their former size.

Junipers and poplars grow down to the river's edge in the mountain regions, where sweetbrier and blackberries also abound. Willows, buckthorn, poplars, and oleasters predominate lower down. The trees along the river's lowest reaches once formed an impenetrable tangle at the river's reed-covered delta, but salt- and drought-resistant plants are now the predominant flora there. Few bird and fish species remain in the depleted and polluted waters of the lower Amu Darya and its delta.

The Amu Darya is largely dependent on the waters of its principal tributaries, the Panj and the Vakhsh, the greater part of whose flow derives from melting snow and ice. The Amu Darya's water volume increases from March to May, when snow melts on the plains and rainfall increases, and the flow is further augmented in June, July, and August as the ice and snow of the mountain ranges thaw. The flow gradually abates from September to February. During winter, ice forms along the banks of the river's upper reaches, and its lower sections may freeze completely for more than two months. As the ice floes begin to disperse in February and March, they jam the river downstream.

Even before its diminished lower reaches were closed to navigation, little transport was conveyed by the Amu Darya because of its unstable riverbed and shoals. A complex system of dams was erected from the mid-20th century, mainly on the lower course, to provide for irrigation and to protect the cultivated fields from floods. A giant (984-foot [300-metre]) dam and hydroelectric station was constructed on the Vakhsh River at Norak (Nurek), Tajikistan, in the 1970s and '80s, but a similar dam at Rogund (Rogun), Tajikistan, was severely damaged by floodwaters in the early 1990s.

Amud, archaeological site in Israel known for its human remains, which provide important evidence of the diversification and development of Middle Eastern Neanderthals. The site is centred on Amud Cave, overlooking the 'Amud River (Wadi el 'Amud) just northwest of the Sea of Galilee.

University of Tokyo expeditions to the site, led in 1961 and 1964 by Hisashi Suzuki, unearthed Neanderthal skeletal remains dating from about 50,000 to 60,000 years ago. Now held in the Rockefeller Archaeological Museum, Jerusalem, these finds consist of a skeleton (designated Amud I) of an adult male about 25 years old, along with a fragment of another adult jaw and skull fragments of two infants. Amud I has a notably large cranial capacity of about 1,740 cubic cm (106 cubic inches). Nonetheless, the skull has Neanderthal features, with a receding forehead, divided brow, and prominent mastoid processes. Though the bones are incomplete, the height of Amud I has been estimated at 172–177 cm (68–70 inches).

In 1991 a joint Israeli and American expe-

dition began new excavations. The following year workers uncovered the partial skeleton of an 8- to 10-month-old Neanderthal baby, upon whose pelvis had been placed the maxilla of a red deer, apparently as a burial rite. Further evidence of Neanderthal habitation and Mousterian toolmaking were revealed, including carved blades and points and deer, bovid, equid, pig, and fox remains. Other hominid remains have been uncovered nearby in the Emireh, Shovakh, and Zuttiyeh caves.

Amul (Iran): see *Āmol*.

amulet, also called **TALISMAN**, an object, either natural or man-made, believed to be endowed with special powers to protect or bring good fortune. Amulets are carried on the person or kept in the place that is the desired sphere of influence—e.g., on a roof or in a field. The terms amulet and talisman are often used interchangeably, but a talisman is sometimes defined as an engraved amulet.

Natural amulets are of many kinds: precious stones, metals, teeth and claws of animals, bones, plants, and so on. Man-made amulets, equally varied, include religious medallions and small figurines. Among believers amulets are thought to derive power from their connection with natural forces, from religious associations, or from being made in a ritual manner at a favourable time.

Neanderthals and other prehistoric peoples used natural amulets in burials, and so-called Venus figurines dating to about 25,000 BC may be among the earliest of man-made amulets. The MacGregor papyrus of ancient Egypt lists 75 amulets. One of the commonest was the scarab beetle, worn by the living and dead alike. The scarab (*q.v.*) symbolized life—perhaps because it pushed a ball of dung that was identified with the sun and was believed to contain the beetle's eggs, or perhaps because its hieroglyph was the same as that for the verb "to become"—and was thought to restore the dead person's heart in the next world. In Egypt the magic formulas originally recited over amulets to give them their power were eventually inscribed and worn themselves.

In the Middle Ages Christian amulets included the traditional relics of saints and letters said to have been sent from heaven. Among Jews the preparation of amulets became a rabbinic function. Muslims today often carry verses from the Qur'an, the names of God, or associated sacred numbers within small satchels. Christians may wear crosses or crucifixes, and statuettes of the Madonna are found in some Roman Catholic households. A popular type of amulet is the "good luck charm" such as the birthstone or rabbit's foot.

Amun (Egyptian god): see *Amon*.

Amundsen, Roald, in full **ROALD ENGELBREGT GRAVNING AMUNDSEN** (b. July 16, 1872, Borge, near Oslo, Nor.—d. June 18, 1928?, Arctic Ocean), Norwegian explorer who was the first to reach the South Pole, the first to make a ship voyage through the Northwest Passage, and one of the first to cross the Arctic by air. He was one of the greatest figures in the field of polar exploration.

Amundsen studied medicine for a while and then took to sea. In 1897 he sailed as first mate on the *Belgica* in a Belgian expedition that was the first to winter in the Antarctic. In 1903, with a crew of six on his 47-ton sloop *Gjøa*, Amundsen became the first man to sail through the Northwest Passage and around the northern Canadian coast; his east-west journey ended at Herschel Island in the Yukon in 1905. This achievement whetted his appetite for the spectacular in polar exploration.

Amundsen's next plan, to drift across the North Pole in Fridtjof Nansen's old ship, the *Fram*, was affected by the news that the American explorer Robert E. Peary had reached the North Pole in April 1909, but he continued his preparations. When Amundsen left

Norway in June 1910 no one but his brother knew that he was heading for the South Pole instead of the North. He sailed the *Fram* directly from the Madeira Islands to the Bay of Whales, Antarctica, along the Ross Sea. The base he set up there was 60 miles (100 km) closer to the pole than the Antarctic base of the English explorer Robert Falcon Scott, who was heading a rival expedition with the same

Roald Amundsen, 1923

UPI/Bettmann

goal. An experienced polar traveler, Amundsen prepared carefully for the coming journey, making a preliminary trip to deposit food supplies along the first part of his route to the pole and back. To transport his supplies, he used sled dogs, while Scott depended on Siberian ponies.

Amundsen set out with 4 companions, 52 dogs, and 4 sledges on Oct. 19, 1911, and, after encountering good weather, arrived at the South Pole on December 14. The explorers recorded scientific data at the pole before beginning the return journey on December 17, and they safely reached their base at the Bay of Whales on Jan. 25, 1912. Scott, in the meantime, had reached the South Pole on January 17, but on a difficult return journey he and all his men perished.

With funds resulting from his Antarctic adventure, Amundsen established a successful shipping business. He acquired a new ship, the *Maud*, and tried in 1918 to complete his old plan of drifting across the North Pole, but he was forced to abandon this scheme in favour of trying to reach the North Pole by airplane. In a flight (1925) with the American explorer Lincoln Ellsworth he arrived to within 150 miles (250 km) of the pole. In 1926, with Ellsworth and the Italian aeronautical engineer Umberto Nobile, he passed over the North Pole in a dirigible, crossing from Spitsbergen (now Svalbard), north of Norway, to Alaska. Disputes over the credit for the flight embittered his final years. In 1928 Amundsen lost his life in flying to rescue Nobile from a dirigible crash near Spitsbergen. Amundsen's books include *The South Pole* (1912) and, with Ellsworth, *First Crossing of the Polar Sea* (1927).

Amundsen Gulf, southeastern extension of the Beaufort Sea of the Arctic Ocean. Extending for 250 miles (400 km), it is bordered by Victoria Island on the east and separates Banks Island (north) from the Canadian mainland (south). In 1850 the gulf was entered from the west by the British explorer Robert McClure, whose expedition became the first—by ship and sledge—to cross the Northwest Passage.

The gulf is named for the Norwegian explorer Roald Amundsen, who was first to traverse the Northwest Passage by ship.

'Amūq, Turkish **AMİK**, plain of southern Turkey, bordering Syria. Framed by mountains, the plain is about 190 square miles (500 square km) in area and forms a triangle between the cities of Antioch (southwest), Reyhanlı (southeast), and Kırıkhan (north). In the centre of the plain is Lake Amik (Lake An-

tioch), which was drained after the mid-20th century. The region's agriculture is based on irrigated cotton.

In the 1930s expeditions led by the American anthropologist Robert J. Braidwood from the Oriental Institute of the University of Chicago cataloged 178 archaeological sites in the 'Amūq plain. Among those later excavated were Tell Al-Judaidah (Judeidah), Tell Kurdu, and Tell Aḡana, or Aḡhana, the ancient city of Alalakh (*q.v.*). These and other tells are the basis for the 'Amūq series, a stratigraphic sequence that traces the chronology of the Middle East from as early as 6000 BC. Research on the plain was renewed by the Oriental Institute in 1995.

Amur, Russian **AMURSKAYA, oblast** (province), far eastern Russia. It occupies the basins of the middle Amur River and its tributary the Zeya and extends up to the crest of the Stanovoy Range. Amur oblast was formed in 1932 from Khabarovsk *krai* (region), and its present boundaries were established in 1948.

The southern part of the oblast, the fertile, black-earth lowland of the Zeya-Bureya Plain, is now largely under cultivation. The higher north and east are almost entirely forested. Most of the population is Russian; the largest of the indigenous groups are the Yakut and Evenk. The chief city and administrative centre is Blagoveschensk (*q.v.*). Wheat is the dominant crop of the lowland. Soybeans, sunflowers, and flax are the main industrial crops. Open-pit coal mining is carried on in the south around Raychikhinsk, and gold and iron ore are found further north. There is also some timber production. The Zeya dam and hydroelectric station on the Zeya River, completed in 1978 with a rated capacity of 1,260 megawatts, was surpassed by the Bureya dam and 1,700-megawatt hydroelectric station, which began operation in 1994.

River navigation is important during the summer. The Trans-Siberian Railroad has crossed the region since 1916, and another major railroad, the BAM (Baikal-Amur Magistral), was constructed in the 1980s. Area 140,400 square miles (363,700 square km). Pop. (1995 est.) 1,041,000.

Amur River, Wade-Giles romanization **HEILUNG CHIANG**, Pinyin **HEILONG JIANG**, Mongol **KHARAMUREN**, river of East Asia, forming part of the frontier between Russia and China.

A brief treatment of the Amur River follows. For full treatment, see **MACROPAEDIA: Asia**.

The headwaters of the Amur rise where the borders of Russia (Siberia), Mongolia, and the Inner Mongolian Autonomous Region of China meet. The Amur proper begins at the confluence of the Shilka and Argun rivers. Downriver the Amur, with a total length of 1,755 miles (2,824 km), flows generally east and southeast along the Russian-Chinese border to Khabarovsk, Siberia. There it turns northeastward and flows across Russian territory to empty into the Tatar Strait of the Pacific Ocean, a narrow channel connecting the Sea of Japan (East Sea; south) and the Sea of Okhotsk (north).

The Amur's drainage basin covers an area of 716,200 square miles (1,855,000 square km), and among the river's major tributaries are the Zeya, Bureya, Sungari, Ussuri, and Amgun rivers. The upper and middle Amur sections flow alternately through mountain valleys and open plateau country. Much of the lower course of the Amur runs between low, often overflowing banks into a vast marsh, the surface of which is broken by channels and dotted with lakes and ponds; the riverbed branches often, and the channel becomes very wide. The Amur River basin has a monsoon climate—a seasonal alternation of winds from the mainland and the ocean. In winter the

dry, cold air from Siberia brings clear, dry weather with strong frost, while in summer the moist ocean winds predominate. The river is fed primarily by monsoon rains that fall in summer and autumn. During the high-water season from May to October, regions of the lower Amur basin often become enormous lakes.

The Amur River is rich in fish; more than 25 species are of commercial value. The river basin was originally populated by hunting and cattle-breeding nomadic tribes. From the 18th century onward the area north of the Amur was settled by Russians along with Ukrainians, Belorussians, Tatars, Latvians, and other internal deportees from European Russia. South of the Amur live Chinese, Mongols, Manchus, and many other peoples. The Amur is navigable throughout its entire course for about half the year. The potential for hydroelectric-power production in the Amur River basin is high, but only limited development has taken place to date.

Amurath (Ottoman sultan): see Murad.

Amursky, Nikolay Nikolayevich Muravyov, Count: see Muravyov, Nikolay Nikolayevich.

Amuzgo, also spelled AMUSGO, ethnolinguistic Indian group of eastern Guerrero and western Oaxaca states, southern Mexico. Their language is related to that of the Mixtec, their neighbours to the north and west. Although many Amuzgo can speak Spanish, the majority (about 65 percent) speak only Amuzgo.

The people are agricultural, using the plow or digging stick to plant staples of corn, beans, and squash, as well as some chilies and tomatoes, and sugarcane as a cash crop. Wild game and seafood are eaten, and farm animals are also kept. Houses are traditionally round thatched huts, two or more for each household. Settlements may be in towns or villages or dispersed. Weaving and pottery are the major crafts practiced, though hammocks, ropes, and nets are also made.

The *compadrazgo*, or godparent relationship, is widely practiced, godparents being chosen at baptism and marriage. Children owe great respect to godparents, and parents and godparents participate in various rituals of kinship. Nominally Roman Catholic, the Amuzgo celebrate their community's patron saint's day and practice baptism and marriage in the church; however, several non-Christian rituals are also observed, and the mythology of the community is non-Christian.

amygdule, secondary deposit of minerals found in a rounded, elongated, or almond-shaped cavity in igneous rock. The cavities (vesicles) were created by the expansion of gas bubbles or steam within lava. Some amygdules consist partially of lava, which indicates their formation during solidification of the rock. Since gas bubbles tend to rise through the lava, amygdules are most common near the tops of flows. The secondary minerals may form after the solidification of the lava; the gases may help to form the filling minerals. A great variety of minerals have been found as amygdules, including some spectacular museum specimens of zeolites.

amyl alcohol, also called PENTYL ALCOHOL, any of eight organic compounds having the same molecular formula, $C_5H_{11}OH$, but different structures. The term is commonly applied to mixtures of these compounds, which are used as solvents for resins and oily materials and in the manufacture of other chemicals, especially amyl acetate, a solvent for nitrocellulose lacquers. Commercial amyl alcohols are colourless liquids, slightly soluble in water, and having a characteristic penetrating odour.

Before the 1920s, the only economical source of amyl alcohol was fusel oil, which is formed as a minor product in the fermentation of carbohydrates to make ethyl alcohol. More abundant and dependable production results from two industrial syntheses that employ hydrocarbons available from petroleum. In the first of these methods, introduced in 1926, the chlorination of pentane gives mixed amyl chlorides that are converted to the desired alcohols by reaction with water and caustic alkali. A second process, introduced in 1953, is based on the reaction of carbon monoxide and hydrogen with butene.

amyl nitrite, drug once commonly used in the treatment of angina pectoris, a condition characterized by chest pain precipitated by oxygen deficiency in the heart muscle. Administered by inhalation, amyl nitrite is a vasodilator (*i.e.*, an agent that expands blood vessels); its action causes all smooth muscle to relax. The drug is useful in treating cyanide poisoning. Side effects include headache, increased heart rate, and low blood pressure. Amyl nitrite is often used illicitly to produce euphoria and to enhance sexual pleasure. On the black market it is known by a variety of other names, including "amy" and "poppers." Abuse of the drug can cause severe toxicity.

amylase, any member of a class of enzymes that catalyze the hydrolysis (splitting of a compound by addition of a water molecule) of starch into smaller carbohydrate molecules such as maltose (a molecule composed of two glucose molecules). Two categories of amylases, denoted alpha and beta, differ in the way they attack the bonds of the starch molecules.

Alpha-amylase is widespread among living organisms. In the digestive systems of humans and many other mammals, an alpha-amylase called ptyalin is produced by the salivary glands, whereas pancreatic amylase is secreted by the pancreas into the small intestine.

Ptyalin is mixed with food in the mouth, where it acts upon starches. Although the food remains in the mouth for only a short time, the action of ptyalin continues for up to several hours in the stomach—until the food is mixed with the stomach secretions, the high acidity of which inactivates ptyalin. Ptyalin's digestive action depends upon how much acid is in the stomach, how rapidly the stomach contents empty, and how thoroughly the food has mixed with the acid. Under optimal conditions as much as 30 to 40 percent of ingested starches can be broken down to maltose by ptyalin during digestion in the stomach.

When food passes to the small intestine, the remainder of the starch molecules are catalyzed mainly to maltose by pancreatic amylase. This step in starch digestion occurs in the first section of the small intestine (the duodenum), the region into which the pancreatic juices empty. The by-products of amylase hydrolysis are ultimately broken down by other enzymes into molecules of glucose, which are rapidly absorbed through the intestinal wall.

Beta-amylases are present in yeasts, molds, bacteria, and plants, particularly in the seeds. They are the principal components of a mixture called diastase that is used in the removal of starchy sizing agents from textiles and in the conversion of cereal grains to fermentable sugars.

amyloidosis, disease characterized by the deposition of amyloid in the connective tissues, inhibiting normal organ functioning. Amyloid is a fibrous protein-carbohydrate complex that is derived from immunoglobulins, a group of proteins that have antibody activity. The disease may affect the whole system or may be localized in tumourlike masses, particularly in the larynx (voice box) or in some other portion of the upper respiratory tract. The localized form is primary—unassociated with any other disease. The systemic form

may be primary or associated with some chronic infection such as tuberculosis or syphilis or with a lasting inflammation such as rheumatoid arthritis. No successful treatment of primary systemic amyloidosis has been devised; some improvement in secondary systemic amyloidosis has been achieved occasionally by successful management of the underlying disease. Localized amyloidosis is treated by surgical removal of the amyloid masses.

Amyntas III (or II) (d. 370/369 BC), king of Macedonia from about 393 to 370/369. His skillful diplomacy created a minor role for Macedonia in Greek affairs and prepared the way for its emergence as a great power under his son Philip II (ruled 359–336).

Amyntas came to the throne during the disorders that plagued Macedonia after the death of the powerful king Archelaus (ruled c. 413–399). Amyntas soon had to fight off attacks by the Illyrians (of present-day Albania) and by the Chalcidian League, a federation of cities of the Chalcidic peninsula, east of Macedonia. The threat from the latter was removed when intervention by Sparta led to the dissolution of the league in 379. Amyntas continued to maintain his independence by siding with the powers ascendant in Greece, including first Athens and then Thessaly, under its tyrant Jason of Pherae (ruled c. 385–370).

Amyot, Jacques (b. Oct. 30, 1513, Melun, near Paris, France—d. Feb. 6, 1593, Auxerre), French bishop and classical scholar famous for his translation of Plutarch's *Lives* (*Les Vies des hommes illustres Grecs et Romains*, 1559), which became a major influence in shaping the Renaissance concept of the tragic hero.

Amyot was educated at the University of Paris and at Bourges, where he became professor of Latin and Greek and translated Heliodorus' *Aethiopia*. For this King Francis I gave him the abbey of Bellocane and commissioned him to complete his translation of Plutarch's *Lives*, on which he had been engaged for some time. He went to Rome to study the Vatican text of Plutarch's *Bioi paralleloi* (*Parallel Lives*). On his return to France he was appointed tutor to the sons of Henry II. Both favoured him on accession, making him grand almoner and, in 1570, bishop of Auxerre, where he spent the rest of his life. Amyot translated seven books of the *Bibliotheca historica* of Diodorus Siculus in 1554, the *Daphnis and Chloë* of Longus in 1559, and the *Moralia* of Plutarch in 1572, as well as the *Lives*.

Amyot's *Vies* was an important contribution to the development of Renaissance humanism in France and England, and Plutarch was an ideal choice because he presented the moral hero as an individual rather than in abstract, didactic terms. Moreover, Amyot supplied his readers with a sense of identification with the past and the writers of many generations with characters and situations to build upon. He also gave the French an example of simple and pure style; Montaigne observed that without Amyot's *Vies*, no one would have known how to write. His reasons were not solely stylistic: Amyot added many new words to the French language, enabling philosophical writers to express thoughts for which only Latin had been adequate previously. Amyot's *Vies* was translated into English by Sir Thomas North (1579) and was the source for William Shakespeare's Roman plays.

amyotrophic lateral sclerosis (ALS), also called LOU GEHRIG'S DISEASE, degenerative nervous-system disorder that causes muscle wasting and paralysis. The disease usually occurs after age 40, more often in men than in women.

ALS affects the motor neurons—*i.e.*, those neurons that control muscular movements.

The muscles innervated by the degenerating neurons become weak and eventually atrophy. The disease has an insidious onset. The early signs are usually weakness of the hands, along with muscle atrophy. The muscular weakness and atrophy slowly creep up the forearms to the shoulders. The lower limbs also become weak and spastic. Fibrillation (rapid twitching) is almost always present. Weakness and spasticity may be present for months before actual atrophy is evident. Death generally results from atrophy of the respiratory muscles.

A variety of ALS in which the neuron degeneration is most pronounced in the spinal cord is termed progressive muscular atrophy. Its symptoms are similar to the above, except that, instead of spasticity in the feet and legs, atrophy and weakness may be present. Victims of progressive muscular atrophy generally survive longer than those suffering from classic ALS.

In progressive bulbar palsy—a variety of ALS in which the degeneration is centred on the neurons of the cranial nerves and brainstem—chewing, talking, and swallowing are difficult. Often there are involuntary outbursts of laughing and crying; tongue fibrillation and atrophy are common. The prognosis is especially bleak in this form of ALS, with death commonly occurring within one to three years of onset.

About 5–10 percent of cases of ALS are the result of genetic inheritance. In 1993 researchers discovered the defective gene responsible for the hereditary form of ALS. The gene produces the enzyme superoxide dismutase, which eliminates free radicals from the body's cells. Free radicals are molecular by-products of normal cell metabolism that can destroy cells if allowed to accumulate in them. In persons with the defective version of this gene, the superoxide dismutase produced is somehow ineffective in neutralizing free radicals, which go on to selectively destroy motor neurons. The discovery of the mutated gene enabled genetic screening to determine potential carriers in families with a history of ALS.

Amyrtaeus OF SAIS, Egyptian king whose reign (404–399 BC) constituted the entire 28th dynasty.

He was possibly a relative of the Amyrtaeus who had earlier aided Inaros, a Libyan prince who had attempted to oust the Achaemenians from the Nile Delta (Lower Egypt). In 404 Amyrtaeus of Sais successfully led a revolt against Achaemenian control of the delta and finally gained control of all of Upper Egypt in 400. Although his rule was plagued by insurrections, the Achaemenians were unable to regain power. Amyrtaeus left no monuments, and very little detailed information is known about his reign. According to a late Egyptian tradition, he in some way transgressed the law, and thus his son was not allowed to succeed him.

An (Mesopotamian god): *see* Anu.

An-ch'ing, formerly (1911–49) HUAI-NING, Pinyin ANQING, conventional ANKING, city situated on the north bank of the Yangtze River in southwestern Anhwei *sheng* (province), China. Situated at a crossing place on the Yangtze, it commands the narrow section of the floodplain between the Ta-pieh Mountains to the north and the Huang Mountains on the south bank, at the west end of the Lower Yangtze Plain. An-ch'ing is the terminus of a highway running northward through Ho-fei, to Pang-pu in northern Anhwei, and on to Shang-ch'iu in southern Honan province. This road joins another, which follows the northern edge of the Yangtze floodplain on its way upstream to Wu-han (in Hupeh province), just south of An-ch'ing.

A county was founded at the site under the Han dynasty (206 BC–AD 220) in the 2nd century BC and was named Wan. In the 4th

century AD it was called Huai-ning—a name it retained until the 20th century. It became the seat of a commandery called T'ung-an under the Sui dynasty (581–618). Under the T'ang (618–907) and Sung (960–1126) dynasties the town was known as the Shu prefecture. The name An-ch'ing was first given to a military prefecture set up there in the late 12th century; this was subsequently transformed into a civil superior prefecture called An-ch'ing. At the beginning of the Ch'ing dynasty (1644–1911), it became the capital of the new province of Anhwei and the administrative seat of its governor-general. It remained the provincial capital until 1949, when it was replaced by Ho-fei; from 1911 to 1949 it was officially known as Huai-ning.

An-ch'ing played an important role during the Taiping Rebellion in the mid-19th century. Taken by the rebel forces in 1853, it remained one of their most important bases until 1861, when it was lost by them after a desperate defense. It was in the vicinity of An-ch'ing that Taiping reforms were most in evidence.

After its recapture the imperial Chinese commander, Tseng Kuo-fan, ordered the establishment there of flour mills, granaries, and munition factories for his armies. From 1861 onward these works were under Chinese management, but, because of the lack of skilled technicians, the products of the arsenal were of little practical use, and after a few years it was shut down.

An-ch'ing became a port of call for foreign shipping under the Chefoo Convention (1876) between China and the United Kingdom, and under the Sino-British trade agreement of 1902 it was to be opened to foreign trade. Little trade resulted, however, since An-ch'ing had no large or rich hinterland and its communications were relatively poor. Later, when railways to the interior of Anhwei reached the Yangtze River further east, its importance declined even more.

An-ch'ing has remained a medium-sized provincial city, an important commercial centre for the plain north of the Yangtze, and a market for tea produced in the mountains both north and south of the river. While also a local cultural centre, it has remained comparatively stagnant after losing its status as provincial capital. Its modern industrial development includes a petrochemical works, producing fuel oils and synthetic ammonia, an oil refinery, and construction of a new port. Pop. (1990 est.) 250,718.

An Chung-sik, also called SHIMJON (Korean: "Spirit Field") (b. 1861, Seoul, Korea—d. 1919, Seoul), the last gentleman painter of the great Korean Yi dynasty (1392–1910).

As a promising young painter, An Chung-sik was sent to China for training by the Korean court. Upon his return he became a master of the popular Southern style, with its emphasis on fingertip technique. He was also a noted calligrapher who mastered all the writing styles. Interested in new trends, especially those from the West, he experimented with ideas of perspective and depth, grafting them to the traditional style. His work furnished the starting point for many younger painters. Toward the end of his life he was the central figure in the establishment (1918) of the Sohwa Hyobhoi ("Association of Painters and Calligraphers").

An-k'ang, Pinyin ANKANG, formerly HSING-AN, city in southeastern Shensi *sheng* (province), China. Situated in the narrow valley of the Han River between the Tsinling and Ta-pa mountain ranges, it has been an important trade centre since antiquity, being situated at the junction of the east-west route via the Han River valley and the route to the north over the mountains to Sian (Ch'ang-an). A rail line, completed in 1978, links An-k'ang with Chungking (in Szechwan province)

and Hsiang-fan (in Hupeh province) via the Han River valley. It is also in an important strategic area near the borders of Szechwan, Shensi, and Hupeh provinces.

It first emerged as an independent administrative centre in the 3rd century AD, under the name Liang-chou. Later, in the 5th century, it took the name Chin-chou, the county town bearing the name Hsi-ch'eng. In 1583 the prefecture was renamed Hsing-an. The county town was renamed An-k'ang in the early 18th century. In 1912 the superior prefecture of Hsing-an was abolished, and it reverted to county status once more. An-k'ang comprised two separate walled towns and was a flourishing centre of trade, having been intimately linked since the 18th century with Han-k'ou. The city became the collecting centre for the agricultural produce of the surrounding area, which had been extensively colonized only since the 17th century. The main products of the area are grains, various types of oilseeds, sesame, hides, and forest products (notably lacquer). Pop. (1990 est.) 142,170.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

An Lu-shan, Pinyin AN LUSHAN, original name (Wade-Giles romanization) K'ANG, imperial name HSIUNG WU, canonized name YEN LA WANG (b. 703—d. 757, Lo-yang, China), Chinese general of Iranian and Turkish descent who, as leader of a rebellion in AD 755, proclaimed himself emperor and unsuccessfully attempted to found a dynasty to replace the T'ang dynasty. Despite its failure, the rebellion precipitated far-reaching social and economic change.

Early life and career. The family name An was derived from the Chinese name for Bukhara in Sogdiana (present Uzbekistan). The given name Lu-shan is a Sincized form of the Iranian *rowshān*, "light." An Lu-shan's ancestors belonged to a group of Sogdians who had been incorporated into the Eastern Turks, and his mother was from a noble Turkish clan.

The Eastern Turks, whose ascendancy in Mongolia dated from the 6th century, had been conquered by the Chinese emperor T'ai-tung at the beginning of the T'ang dynasty but had made themselves independent and were enjoying renewed prosperity at the time of An Lu-shan's birth. The death of their ruler, Qapaghan Qaghan, in 716, however, led to disorder and strife, and the Ans sought refuge in China. Just at that period the frontier policies of the emperor Hsüan Tsung (reigned 712–756) were providing opportunities for men such as An Lu-shan, his cousin An Ssu-shun, and other soldiers of non-Chinese origin to serve in the Chinese armies. Their rise to positions of command was further aided after 736 by the dictatorial rule of China's chief minister, Li Lin-fu, who was unwilling to appoint native Chinese as generals for fear that they would gain prestige that would enable them to rival his own position at court.

An Lu-shan's military career took place on the northeastern frontier in what is now southern Manchuria. The first occurrence of his name in the T'ang annals is under the year 736, when, as a reconnaissance officer, he lost his force through rash conduct and was condemned to death. He was pardoned and, thereafter, rose rapidly in rank, receiving his first independent command in 742. As a military governor he became a political figure, made frequent visits to the capital, and became a personal favourite of the emperor and his consort, the celebrated beauty Yang Kuei-fei. An Lu-shan, an enormously fat man, was

adept at playing the buffoon in order to ingratiate himself. Such was his favour at court that once, three days after his birthday, he was taken into the women's quarters of the palace (wrapped in an enormous baby diaper) and put through a mock ceremony of adoption by Yang Kuei-fei. Indecorous conduct of this kind led to rumours of improper relations between him and Yang Kuei-fei, which have added spice to the later legend, but his position at court depended at least as much on the emperor himself as on his consort.

An Lu-shan's rebellion. By the time of Minister Li Lin-fu's death in 752, An Lu-shan had accumulated three frontier provinces under his command and was the most powerful general in the empire. After the dictator's demise an intense struggle developed between An Lu-shan and Yang Kuo-chung, the cousin of Yang Kuei-fei, who attempted to take over Li Lin-fu's position. Though Yang Kuo-chung could attack and destroy An Lu-shan's supporters at court, he was unsuccessful in his attempts to establish a countervailing military base in the provinces or to undermine An Lu-shan's position in the northeast, and he only succeeded in exacerbating An Lu-shan's suspicions and frustrations. Finally, toward the end of 755, alleging that he had received a secret command from the emperor to get rid of Yang Kuo-chung, An Lu-shan turned his large, war-hardened army inward and marched on the capital.

Within a month the rebels had taken the eastern capital, Lo-yang, and at the beginning of the lunar year corresponding to 756 An Lu-shan proclaimed himself emperor of the Great Yen dynasty.

Meanwhile, loyal T'ang forces had been mobilized and had taken up defensive positions in the narrow pass up the Huang Ho (Yellow River) leading into Shensi province. For six months the rebels were unable to advance. There was great suspicion and rivalry between Yang Kuo-chung and Ko shu-han, the general in charge of the defense of the eastern approaches to Ch'ang-an, capital of China. Fearing a coup against himself, Yang Kuo-chung goaded Ko shu-han into abandoning his defensive posture and moving eastward against the rebels. The T'ang army was routed, and the way to Ch'ang-an was left open. The emperor hastily abandoned the city and fled westward. At Ma-wei, a small village west of the capital, his guard mutinied, assassinated Yang Kuo-chung, and demanded the death of the emperor's favourite, Yang Kuei-fei. The emperor reluctantly consented, and her assassination became the theme of the great poet Po Chü-i's "Everlasting Remorse" and of countless other works of art.

Although An Lu-shan's forces occupied Ch'ang-an, he himself remained behind in Lo-yang. By this time he was seriously ailing, perhaps with diabetes. He was nearly blind and suffered from extreme irascibility, which made his attendants go in constant fear of their lives. At the beginning of 757 he was murdered by a eunuch slave with the connivance of his own eldest son, An Ch'ing-hsü, and others. The rebellion dragged on for several years, first under An Ch'ing-hsü, then under a former subordinate, Shih Ssu-ming, then under Shih Ssu-ming's son, Shih Ch'ao-i. Finally in 763 it officially came to an end with the defeat and death of Shih Ch'ao-i. A major role in the defeat of the rebels was played by contingents sent by the Uighurs, who had replaced the Eastern Turks as masters of the eastern steppes and who were traditional allies of T'ang. By this time the T'ang government was too exhausted to undertake a thorough pacification of the rebel territory, and the surviving rebel generals were allowed to surrender and remain in command of the regions they

occupied in return for a nominal submission to T'ang. Other parts of the country fell under the control of T'ang generals who were almost as insubordinate as the former rebels. The second half of the T'ang dynasty and the following Five Dynasties period were troubled by a chronic warlordism that only came to an end with the rise of the Sung dynasty in 960.

After his death, An Lu-shan became the object of a cult on the northeastern frontier among the non-Chinese soldiers who constituted the bulk of the army and whose aspirations he symbolized. Conversely, the non-Chinese, "barbarian" character of the rebellion was influential in stirring up the xenophobic sentiments of the Chinese that increasingly characterized the second half of the T'ang dynasty, in marked contrast to the receptive, cosmopolitan attitudes of the first half.

BIBLIOGRAPHY. E.G. Pulleyblank, *The Background of the Rebellion of An Lu-shan* (1955), places the man and his rebellion in historical context. Howard S. Levy, *Biography of An Lu-Shan* (1960), is a translation of the official biography. R. des Rotours, *Histoire de Ngan Lou-chan* (1962), is a scholarly and thoroughly annotated translation from a large collection of source material on An Lu-shan.

An-p'ing, town, seaport, and district of T'ai-nan *shih* (municipality), southwestern Taiwan, the traditional outpost for T'ai-nan. It is the oldest Chinese settlement in southern Taiwan, dating from the late 16th century. It is connected to T'ai-nan proper by canal and by light railway. Until the late 19th century, An-p'ing was a busy port, with strong commercial connections with Foochow and Amoy and other ports on the Chinese mainland. The harbour, however, was always shallow and subject to silting, and by the early 1970s it was largely reduced to use as a fishing harbour. The growth of nearby Kao-hsiung to the south and the construction of the railway system, giving T'ai-nan access both to Kao-hsiung and Chi-lung at the northern end of Taiwan, led to An-p'ing's rapid decline. Pop. (1989 est.) 19,434.

An-shan, Pinyin ANSHAN, city in central Liaoning *sheng* (province), China. It lies about 50 miles (80 km) southwest of Shen-yang (Mukden). Originally a post station on the road from China proper to Liao-yang, 15 miles

Steelworks in An-shan, Liaoning province, China
Jorgen Bitsch—Black Star

(24 km) to the northeast, An-shan was established in 1387 and was fortified in 1587 as part of the defenses set up by the Ming dynasty (1368–1644) against the rising power of the Manchus. Under the Ch'ing (Manchu) dynasty (1644–1911), however, its walls fell into decay, and during the Boxer Rebellion (an anti-foreign uprising in 1900) the town was destroyed by fire. Further destruction followed during the Russo-Japanese War (1904–05), which reduced it to little more than an impoverished village.

Modern An-shan grew up some 6 miles (10 km) north of the old town and was entirely industrial in its origins. In 1909 extensive iron-ore deposits were found in the area. There are further iron deposits in a belt around An-shan at the towns of Ta-ku-shan, Ying-t'ao-yüan, and Kung-ch'ang-ling. The South Manchurian Railway established an ironworks at An-shan in 1918, but production was low until initial difficulties, caused by the low grade of the iron ore, were overcome by new techniques. Under the Japanese occupation after 1931, An-shan was at first a producer of pig iron for use in the Japanese steel industry, but a local steelworks was established, and production began in 1935. In 1937 An-shan was taken over by the Manchurian Heavy Industry Company, a company partly backed by the Manchukuo government, the Japanese puppet regime in Manchuria. The industry concentrated on the production of steel for armaments, and the city expanded rapidly. In addition to the steelworks, various heavy engineering plants were built, and a shortage of coking coal ended with the development of coal mining at Fu-hsin and elsewhere.

After World War II, An-shan suffered from looting by Soviet forces, who removed most of the advanced equipment. The plant had been heavily bombed toward the end of the war and was further damaged during civil warfare that followed the Soviet withdrawal. By 1948 the population had fallen, and steel production had virtually ceased. After 1949 the rehabilitation of heavy industry at An-shan and elsewhere became a major goal of the Communist government. Under the First Five-Year Plan (1953–57) An-shan was built up again into the major iron and steel complex in China and was reequipped with the latest equipment, much of it from the Soviet Union. By 1957 it was producing a wide variety of steel products (such as heavy rails, steel plates, seamless tubes, and alloy steels). An-shan also produced equipment for other major iron and steel complexes elsewhere in China. By the late 1950s it was producing more than 40 percent of the total Chinese production of iron and steel. As the chief centre for industrial development, numbers of technicians and workers were sent to An-shan from other parts of the country for training. An-shan suffered from the withdrawal of Soviet aid in 1960 and the industrial cutbacks that followed, but the city recovered. By the early 1980s it was producing one-fourth of China's steel.

In the 1960s the attempt simply to increase productive capacity was replaced by efforts to make specialized products, which had previously been imported. In the late 1970s An-shan was China's chief centre for metallurgical research and technological innovation in the steel industry. It was also a centre of the engineering industry. Industrial products include tractors, chemicals, cement, and paper.

An-shan is part of a well-integrated industrial complex in the southern section of the Northeast (Manchuria). It is supplied with coal from Fu-hsin, Fu-shun, and Pen-ch'i, magnesium from Ta-shih-ch'iao, and obtains food largely through Liao-yang. Its steel production is supplied to the engineering and machine building industry in other large cities in the Northeast. It also has an oil refinery. It ranks as the fourth industrial city in China by capacity, being exceeded only by Shang-

hai, Tientsin, and Wu-han. An-shan is connected by railway with Shen-yang and with the port city of Lü-ta to the south in Liaoning Province, and an express highway from Ch'ang-ch'un, Kirin Province, to Lü-shun and Lü-ta passes through An-shan. Pop. (1999 est.) 1,285,849.

An-shun, Pinyin *ASHUN*, city, west-central Kweichow *sheng* (province), China, 48 miles (77 km) west of Kuei-yang on the Kuei-yang-K'un-ming railway. An-shun is a county-level municipality (*shih*) and the administrative centre of An-shun prefecture (*ti-ch'ü*). Referred to as the backland of Kweichow, An-shun has long been a strategic thoroughfare on the route between Yunnan and Kweichow. The area was known as Yeh-lang state during the period of Warring States (475–221 BC). It was established as a prefecture in 1383 during the Ming dynasty, and it became a county-level municipality in 1958.

An-shun is situated at the centre of various radiating highways covering the entire western part of the province. It is the chief market and commercial centre for the district, acting as a collecting centre for agricultural produce and as a distribution point for manufactures from Kuei-yang. Its major industries include the manufacture of farm equipment, textiles, and astro-navigation instruments. Large coal reserves in the region supply a large power plant at Hsüan-wei to the west in Yunnan. An-shun is known for its traditional wax printing (*batik*) and clothing industries. A nearby karst region, with its underground stream, gorges, and caverns, is popular with tourists. Pop. (1999 est.) 217,215.

An-yang, Pinyin *ANYANG*, city, northern Honan *sheng* (province), northeastern China, on the An-yang River, a tributary of the Wei River. It was important in history as the site of the ancient city of Yin, the capital of the Shang dynasty from 1384 to 1111 BC; the Shang

that developed more than half a millennium before the beginning of authentic Chinese history in 776 BC. This discovery has provided the most authentic evidence to date of the ancient civilization of China. The site of the Shang capital at An-yang had been known to scholars since the beginning of the 20th century through the accidental discovery of inscribed oracle bones, the earliest Chinese written records. It was not until 1928, however, that the first organized scientific expedition started systematic excavation of these remains under the auspices of Academia Sinica, organized by the Nationalist government of the Republic of China. Fieldwork was carried out by the archaeologist Li Chi from 1928 until the Japanese invasion in 1937. The finds include building foundations, bronzes, chariots, pottery, stone and jade, and thousands of oracle bones. Several other excavations were conducted after 1950.

An-yang has been a regional agricultural and trade centre for centuries. In modern times, it became a station on the main north-south rail line from Peking (Beijing) to Canton (Guangzhou). Coal mining is important. An-yang's textile mills and food-processing plants have been supplemented by heavier manufactures since the communists came to power in 1949. Pop. (1999 est.) 527,982.

found as plankton in shallow water and on moist soil. There are both solitary and colonial forms, the latter resembling a closely related genus, *Nostoc*. In northern latitudes during the summer months *Anabaena* may form water blooms that remain suspended instead of forming a surface scum. A toxic substance produced by *Anabaena* is fatal to cattle and other animals if present in drinking water in sufficient concentration.

Anabaptist, also called **REBAPTIZER**, member of radical, or left-wing, movement of the 16th-century Protestant Reformation. Its most distinctive tenet was adult Baptism. In the first generation of the movement, converts submitted to a second Baptism, which was a crime punishable by death under the legal codes of the time. The Anabaptists, of course, denied that they were rebaptizers, for they repudiated their own infant Baptism as a blasphemous formality. They considered the public confession of sin and faith, sealed by adult Baptism, as the only proper Baptism. Following the Swiss Reformer Huldrych Zwingli, they held that infants were not punishable for sin until an awareness of good and evil emerged within them, and that then they could exercise their own free will, repent, and accept Baptism.

The Anabaptists also believed that the church, which to them was the community of the redeemed, should be separated from the state, which for them existed only for the punishment of sinners. Most Anabaptists opposed the use of the sword by Christians in the maintenance of social order and in the conduct of a just war. They also refused to swear civil

oaths. For their beliefs thousands of Anabaptists were put to death.

The Anabaptists did not aim to reform the medieval church. They were determined instead to restore the institutions and the spirit of the primitive church and were quite confident that they were living at the end of all ages. They readily recognized in their leaders divinely summoned prophets and apostles, and all converts stood ready to give a full account of their faith before the magistrates. They often identified their suffering with that of the early Christian martyrs.

The Anabaptist movement originated in Zürich among a group of young intellectuals who rebelled against Zwingli's apparent subservience to the magistrates and his reluctance to proceed swiftly with a complete reform of the church. One of their leaders was Konrad Grebel, a highly educated Humanist from a patrician family. The first adult baptisms took place at Zollikon, outside Zürich, at the beginning of 1525, and soon a mass movement was in progress. Some of the more distinctive convictions of the Swiss movement were set forth in the seven articles of the Schleitheim Confession (1527), prepared under the leadership of Michael Sattler.

The vehemence and intransigence of the Anabaptist leaders and the revolutionary implications of their teaching led to their expulsion from one city after another. This simply increased the momentum of an essentially missionary movement. Soon civil magistrates took sterner measures, and most of the early Anabaptist leaders died in prison or were executed.

Thomas Müntzer was among those (sometimes called "spirituals") who emphasized that the Anabaptists were living at the end of all ages. He was executed after leading Thuringian peasants in the revolt of 1525. His disciple Hans Hut (died in prison in Augsburg in 1527) was the principal radical Reformer in southern Germany.

Balthasar Hubmaier (executed in Vienna in 1528) was a leader in Nicholsburg, Moravia. Also in Moravia, where the ruling lords desired colonists and where many Anabaptists settled, a type of Anabaptism developed that stressed the community of goods modeled on the primitive church in Jerusalem. Under the leadership of Jakob Hutter the growing communistic colonies assumed his name. Hutterite groups survived, located primarily in the western United States and Canada.

Melchior Hofmann was the Anabaptist apostle in the Netherlands, where he developed a very large following. He taught that the world would soon end and that the new age would begin in Strasbourg, where he was imprisoned in 1533 and died c. 1543.

Some of Hofmann's followers came under the influence of the Dutchman Jan Mathijs (died 1534) and John of Leiden (Jan Beuckelson; died 1535). The two leaders and many refugees settled in 1534 in Münster, Westphalia, where they gained control of the city, established a communistic theocracy, and practiced polygamy. The city was captured in 1535 by an army raised by German princes, and the Anabaptist leaders were tortured and killed.

Modern historians have come to see the episode at Münster as an aberration of the Anabaptist movement. In the years following the episode, however, classical Protestants and Catholics increased the persecution of Anabaptists throughout Europe without discrimination between the belligerent minority and the pacifist majority. The pacifist Anabaptists in the Netherlands and north Germany rallied under the leadership of the former priest Menno Simons and his lieutenant, Dirk Philips. Their followers survived and were eventually accepted as the Mennonite (*q.v.*) religious group. See also Hutterite.

palace stood about 10 miles (16 km) west of the present city. An-yang declined when the succeeding Chou capital arose at Lo-yang.

Modern excavations have revealed historical remains of the Shang, fully illustrating the splendour and advanced stage of a civilization

Anabasis, in full ANABASIS KYROU (Greek: "Upcountry March"), prose narrative, now in seven books, by Xenophon, of the story of the Greek mercenary soldiers who fought for Cyrus in his attempt to seize the Persian throne from his brother, Artaxerxes II. It contains a famous account of the mercenaries' long trek ("the march of the 10,000") from near Babylon to the Euxine (Black Sea) after Cyrus' defeat at the Battle of Cunaxa (401 BC). Xenophon, who had accompanied the force in a private capacity, was largely responsible for their successful retreat through his resourcefulness and courage.

The first part, written at Scillus in the Greek Peloponnese soon after 386 BC, is a lively, detailed, and vivid narrative. It was first published under a pseudonym, Themistocles of Syracuse. The second part, written about 377 BC, is marred by a self-justifying tone and was probably composed in reply to a rival public account that Xenophon considered unfair.

anabatic wind, also called UPSLOPE WIND, local air current that blows up a hill or mountain slope facing the Sun. During the day, the Sun heats such a slope (and the air over it) faster than it does the adjacent lowland because the slope's surface is more nearly perpendicular to the Sun's rays. This warming decreases the density of the air, causing it to rise. More air rises from below to replace it, producing a wind. An anabatic wind may attain a velocity of 6 metres per second (about 13 miles per hour).

anabolism, also called BIOSYNTHESIS, the sequences of enzyme-catalyzed reactions by which relatively complex molecules are formed in living cells from nutrients with relatively simple structures. Anabolic processes, which include the synthesis of such cell components as carbohydrates, proteins, and lipids, require energy in the form of energy-rich compounds (e.g., adenosine triphosphate) that are produced during breakdown processes (see catabolism). In growing cells, anabolic processes dominate over catabolic ones; in non-growing cells, a balance exists between the two.

Anacardiaceae, the sumac family of flowering plants in the order Sapindales, with about 70 genera and 650 species of evergreen or deciduous trees, shrubs, and woody vines. It is native to tropical and subtropical areas of the world, but a few species occur in temperate regions. Members of the family have resin ducts in the bark, leaves usually composed of leaflets in various arrangements, flowers often

with only male or female parts, and usually fleshy fruits. The pistachio (*Pistacia vera*) and cashew (*Anacardium occidentale*) produce edible nuts, and mango (*Mangifera indica*), mombin (*Spondias*), and Kallir plum (*Harpephyllum caffrum*) have edible fruits. The mastic tree (*Pistacia lentiscus*) and the varnish tree (*Rhus vernicifera*) contain useful oils, resins, and lacquers. The reddish brown wood of quebracho (trees of the genus *Schinopsis*, especially *S. lorentzii*) yields commercial tannin. The Peruvian pepper tree (*Schinus molle*), *Cotinus* species, and several species of sumac (*Rhus*) are cultivated as ornamentals. Poison ivy, poison oak, and poison sumac (all *Toxicodendron*, or, according to some authorities, *Rhus*) are irritating to the skin.

anachronism (from Greek *ana*, "back," and *chronos*, "time"), neglect or falsification, intentional or not, of chronological relation. It is most frequently found in works of imagination that rest on a historical basis, in which appear details borrowed from a later age; e.g., a clock in William Shakespeare's *Julius Caesar*, an attendant to the Pharaoh shod in tennis shoes in Cecil B. deMille's *The Ten Commandments*. Anachronisms originate in disregard of the different modes of life and thought that characterize different periods or in ignorance of the facts of history.

Anachronisms abound in the painting of Raphael and the plays of Shakespeare. Artists tended to represent characters in terms of their own nationality and time. The Virgin has been pictured both as an Italian peasant and as a Flemish housewife; Alexander the Great appeared on the French stage down to the time of Voltaire in the full costume of Louis XIV. Modern realism, the progress of archaeological research, and the scientific approach to history came to make an unconscious anachronism an offense. But anachronisms may be introduced deliberately for a burlesque, satiric, or other effect; by contrasting contemporary customs or morals with an alien age, the writer or artist reevaluates the past or present, or both. Thus Mark Twain wrote of a Connecticut Yankee visiting King Arthur's court, and the Belgian James Ensor painted Christ entering Brussels (1888).

Anacletus, SAINT, also called CLETUS, or ANENCLLETUS (fl. 1st century AD; feast day April 26), second pope (76–88 or 79–91) after St. Peter. According to St. Epiphanius and the priest Tyrannius Rufinus, he directed the Roman Church with St. Linus, successor to St. Peter, during Peter's lifetime. He died, probably a martyr, during the reign of Domitian.

Anacletus (II), original name PIETRO PIERLEONI (b. Rome [Italy]—d. Jan. 25, 1138, Rome), antipope from 1130 to 1138 whose claims to the papacy against Pope Innocent II are still supported by some scholars. After study in Paris, he became a monk at Cluny and was made cardinal at Rome in 1116 by Pope Paschal II. In 1118 he accompanied Pope Gelasius II, who fled to France from the persecuting Frangipani, an influential Roman family.

After the death of Pope Honorius II in 1130, a majority of cardinals elected Pietro as successor with the name of Anacletus II, while a minority elected Cardinal Gregorio Papareschi (Innocent II) as successor. The claimants were both consecrated on February 23, leading to a serious schism. Anacletus, backed by most Romans and by the Frangipani, forced Innocent to flee from Rome to France, where he was supported by Abbot St. Bernard of Clairvaux, who attacked Anacletus' Jewish ancestry. Although Anacletus was allied with the ambitious and powerful Roger II after investing him as king of Sicily (1130), Innocent's supporters, including the Holy Roman emperor Lothair II and the Byzantine emperor John II Comnenus, were overwhelming.

The Council (1130) of Étampes, France, convoked by King Louis VI the Fat to decide the legitimacy of the papal succession, chose Innocent. In 1132 Lothair, accompanied by Innocent and Bernard, led a German army into Italy and, by early summer, occupied all Rome except that section held by the Anacletans, who, upon Lothair's departure, again forced Innocent out of Rome. He fled to Pisa, where in 1134 he held a council that excommunicated Anacletus. Lothair's second expedition (1136–37) expelled Roger from southern Italy. Anacletus, with little remaining support, died amid the aftermath of this crisis. In 1139 the second Lateran Council convoked by Innocent ended the schism, though opinion remained divided.

Anaconda, city, former seat (1883) of Deer Lodge county, southwestern Montana, U.S., 23 miles (37 km) northwest of Butte. Laid out in 1883 as Copperopolis by Marcus Daly, founder of Montana's copper industry, the settlement grew rapidly after 1884 when Daly built a copper smelter on nearby Warm Springs Creek. The plant became one of the world's largest nonferrous and reduction works, and its 585-foot (178-metre) smokestack dominates the landscape. The city was incorporated in 1888 and was renamed Anaconda, after Daly's mining camp in Butte, to avoid confusion with Copperopolis in Meagher county. Daly, who had hoped to make it the state capital, built there Hotel Marcus Daly, then one of the most ornate in the nation. His newspaper, the *Anaconda Standard*, had a plant as modern as any in New York City at the time, though it had a readership of only a few thousand. In 1977, the governments of Anaconda and Deer Lodge county were consolidated to form the city of Anaconda-Deer Lodge county.

Copper smelting and the manufacture of phosphate products remained the city's economic mainstay until 1980, when Atlantic Richfield Company, the owner of the Anaconda Company, permanently closed the copper smelter, putting some 25 percent of Anaconda's workforce out of work.

Recreation areas include nearby Deerlodge National Forest, Lost Creek State Park, and Georgetown Lake. Pop. (1990) 10,278.

anaconda (*Eunectes*), either of two South American snakes belonging to the family Boidae. The giant anaconda, or great water

Giant anaconda (*Eunectes murinus*)
Copyright © 1971 Z. Leszczynski—Animals Animals

boa (*Eunectes murinus*), is a heavily built snake usually not more than about 5 m (16 feet) long, but a 7.6-metre specimen is known, and even longer specimens have been reported. If reports in excess of 9 m are accepted, the giant anaconda rivals the largest pythons in length. The yellow anaconda (*E. noteus*) is much smaller.

The giant anaconda is typically dark green with alternating oval black spots. It occurs along tropical rivers east of the Andes and in Trinidad. At night it lies in the water waiting to kill, by constriction, creatures as large as young pigs and caimans that come to drink; occasionally, the anaconda forages in trees for birds. This species bears about 75 live young at a time.

Poison oak (*Toxicodendron diversiloba*)
Barry Lopez—Photo Researchers

Anaconda Company, one of the largest American mining companies, producing copper, aluminum, silver, and uranium. Since 1977 it has been a subsidiary of Atlantic Richfield Company. The company's headquarters are in Denver, Colo., U.S.

In 1882 Marcus Daly, an Irish immigrant, and George Hearst, father of publisher William Randolph Hearst, built Anaconda's first copper mine and smelter in Montana. Anaconda grew to become the world's largest copper producer, and in 1899 the company was purchased by the Standard Oil Trust. The deal created a national scandal when it was discovered that officers of the trust had made huge profits by selling public stock in the new company before the old owners had been paid.

In 1914 Anaconda started buying into foreign mining companies. By 1929 the company owned all of Chile Copper Company, whose Chuquicamata mine was the world's most productive. In 1971 Chile's newly elected Socialist president, Salvador Allende, expropriated Anaconda's Chilean copper mines under powers granted by an amendment to Chile's constitution. The Allende government was toppled in 1973, and the new government agreed to pay Anaconda more than \$250,000,000 for its expropriated mines.

Losses from the Chilean takeover, however, had seriously weakened the company's financial position, and in 1977 the company was sold to Atlantic Richfield Company (ARCO), a diversified energy corporation.

Anacreon (b. c. 582 BC, Teos, Ionia [now Sighajik, Turkey]—d. c. 485), ancient Greek poet who was, after Archilochus, the most important writer of personal lyric poetry in the Ionic dialect. Only fragments of his verse have survived.

Anacreon's working life was mainly associated with the courts of tyrants who were important patrons of art and literature in the 6th century BC. He spent much of his life at the court of Polycrates of Samos, and later he lived at Athens, writing under the patronage of the tyrant Hipparchus. His popularity in Athens continued even after Hipparchus' assassination in 514.

Though Anacreon may well have written serious poems, those that were quoted by later writers are chiefly in praise of love, wine, and revelry. Anacreon disliked the excessive and the unrefined, however, and his treatment of these subjects is unusually formal and elegant. His language and use of metre are smooth and simple, while his outlook is one of ironic enjoyment of life.

Ancient Greek scholars in Alexandria had an edition of his work consisting of five books of verse, of which various fragments are extant. Anacreon's poetic sentiments and style were widely imitated by Hellenistic and Byzantine Greek writers, though they tended to exaggerate the strain of drunken eroticism and frivolity present in his work. There thus arose the *Anacreontea*, a collection of about 60 short poems composed by postclassical Greek writers at various dates and first published by Henri Estienne as the work of Anacreon in 1554. These had a great influence on Renaissance French poetry. The word "Anacreontics" was first used in England in 1656 by Abraham Cowley to denote a verse measure supposedly used by the ancient Greek poet and consisting of seven or eight syllables with three or four main stresses. Anacreon himself, it should be noted, composed verse in a variety of Greek lyric measures. Robert Herrick, William Oldys, and William Shenstone wrote original Anacreontics in English, and Thomas Moore provided perhaps the finest translation of the *Anacreontea* in 1800 under the title *Odes of Anacreon*. The *Anacreontea* also influenced Italian and German literature.

Anadarko, city, seat (1907) of Caddo county, southwest-central Oklahoma, U.S. It lies along

the Washita River. Founded in 1901 when the site was opened to white settlement, its name is a corruption of Nadako, a Caddo Indian tribe. Anadarko is the site of the Southern Plains Indian Museum and Crafts Center, the National Hall of Fame for Famous American Indians, an area office of the Bureau of Indian Affairs, and the Riverside Indian School (1871). Indian City U.S.A. (a reconstruction of tribal villages) is nearby. The annual American Indian Exposition is held there. Anadarko is an agricultural trading and processing centre with some light industry, notably carpet milling. Oil and natural gas wells are in the vicinity. Pop. (1990) 6,586.

Anadyr, formerly (until 1920) NOVO-MARI-INSK, town and administrative centre, Chukchi autonomous *okrug* (district), far northeastern Russia. It lies on the southern shore of the estuary of the Anadyr River, which empties into the Bering Sea. Incorporated as a town in 1965, it is a port on the Northern Sea Route and has a meteorologic station and a fishery factory. Small amounts of lignite (brown coal) for local needs are mined nearby. Pop. (1993 est.) 15,200.

Anadyr, Gulf of, also called ANADYR BAY, Russian ANADYRSKY ZALIV, gulf in far eastern Russia, in the northwestern part of the Bering Sea. The width of the gulf at its entrance is about 250 miles (400 km), and it runs inland for some 200 miles (320 km), extending into the Bay of Krest and the Anadyr River estuary. The Gulf of Anadyr is closed by floating ice for 10 months of the year. On the estuary of the Anadyr lies the port of Anadyr, serving the Chukchi Peninsula.

anaemia: see anemia.

anaesthetic: see anesthetic.

Anagni, town, Frosinone *provincia*, Lazio (Latium) *regione*, central Italy. It lies on a hill above the Sacco Valley, southeast of Rome. The ancient Agnania, capital of the Hernici people, lost its independence to Rome in 306 BC. A bishopric from the 5th century AD, it was besieged by the Arabs in 877. Its leading medieval families were the Conti and Caetani. It was a papal residence in the Middle Ages and the birthplace of four popes: Innocent III, Gregory IX, Alexander IV, and Boniface VIII, who was imprisoned there by the French for three days in 1303. The town's notable landmarks include the cathedral (begun 1074) with a fine triple apse, the 14th-century Casa Barnekow, and the Palazzo Comunale (begun 1163). The ancient city walls still stand.

Anagni is an agricultural centre and has distilling, gas, and rubber industries. Pop. (1993 est.) mun., 19,412.

anagnorisis (Greek: "recognition"), in a literary work, the startling discovery that produces a change from ignorance to knowledge. It is discussed by Aristotle in the *Poetics* as an essential part of the plot of a tragedy, although anagnorisis occurs in comedy, epic, and, at a later date, the novel as well. Anagnorisis usually involves revelation of the true identity of persons previously unknown, as when a father recognizes a stranger as his son, or vice versa. One of the finest occurs in Sophocles' *Oedipus Rex* when a messenger reveals to Oedipus his true birth, and Oedipus recognizes his wife Jocasta as his mother, the man he slew at the crossroads as his father, and himself as the unnatural sinner who brought misfortune on Thebes. This recognition is the more artistically satisfying because it is accompanied by a *peripetia* ("reversal"), the shift in fortune from good to bad that moves on to the tragic catastrophe. An anagnorisis is not always accompanied by a *peripetia*, as in the *Odyssey*, when Alcinous, ruler of Phaeacia, has his minstrel entertain a shipwrecked stranger with songs of the Trojan War, and the stranger begins to weep and reveals himself

as none other than Odysseus. Aristotle discusses several kinds of anagnorisis employed by dramatists. The simplest kind, used, as he says, "from poverty of wit," is recognition by scars, birthmarks, or tokens. More interesting are those that arise naturally from incidents of the plot.

anagram, the transposing of the letters of a word or group of words to produce other words that possess meaning, preferably bearing some logical relation to the original. The construction of anagrams is of great antiquity. Their invention is often ascribed without authority to the Jews, probably because the later Hebrew writers, particularly the Kabbalists, were fond of them, asserting that "secret mysteries are woven in the numbers of letters." Anagrams were known to the Greeks and Romans, although known Latin examples of words of more than one syllable are nearly all imperfect. They were popular throughout Europe during the Middle Ages and later, particularly in France, where a certain Thomas Billon was appointed "anagrammatist to the king."

The making of anagrams was an exercise of many religious orders in the 16th and 17th centuries, and the angelical salutation "Ave Maria, gratia plena, Dominus tecum" ("Hail Mary, full of grace, the Lord is with thee") was a favourite base; it was transposed to hundreds of variations, as, for example, "Virgo serena, pia, munda et immaculata" ("Virgin serene, holy, pure, and immaculate"). Among other anagrams is that from Florence Nightingale into "Flit on, cheering angel." The pseudonyms adopted by authors are often anagrams. In the 20th century, anagrams frequently have been used in crossword puzzles, in both the clues and the solutions.

Anaheim, city, Orange county, California, U.S. It lies on the plain of the Santa Ana River, 25 miles (40 km) southeast of Los Angeles. It was founded by German immigrants in 1857 as a cooperative agricultural community, and its name corresponds to "home on the Ana." After 1950 the community's citrus groves and vineyards had all but disappeared with the Los Angeles-Orange County urban-industrial expansion. Disneyland amusement park (1955), Anaheim Stadium (1966; home of the California Angels baseball team), and Anaheim Convention Center all have become major economic assets of the city. Anaheim forms a metropolitan complex with the cities of Santa Ana and Irvine. Inc. 1915. Pop. (1992 est.) city, 276,314; Orange County MSA, 2,500,181.

Anāhiti, also called ANĀHITĀ, ancient Iranian goddess of royalty, war, and fertility; she is particularly associated with the last. Possibly of Mesopotamian origin, her cult was made prominent by Artaxerxes II, and statues and temples were set up in her honour throughout the Persian empire. A common cult of the various peoples of the empire at that time, it persisted in Asia Minor long afterward. In the Avesta she is called Ardvī Sūrā Anāhītā ("Damp, Strong, Untainted"); this seems to be an amalgam of two originally separate deities. In Greece Anāhiti was identified with Athena and Artemis.

Anáhuac, historical and geographic region of Mexico. The heartland of Aztec Mexico, Anáhuac (Nahuatl: "Land by the Water") designated that part of New Spain that became independent Mexico in 1821. The original Anáhuac of the Aztecs was the central plateau valley of Mexico, an area about 50 miles (80 km) long by 30 miles wide, with an average elevation of 7,500 feet (2,300 m). When the Spaniards arrived in 1519, the valley contained five interlocking lakes (Zumpango.

Xaltocan, Texcoco, Xochimilco, and Chalco), in the midst of which stood Tenochtitlán (now Mexico City), the Aztec capital, linked to the mainland by three long causeways. In 1607–08 much of the water was drained off to the Pánuco River system by a ditch and tunnel, and in the 20th century Lake Texcoco was further emptied. Its salt marshes remain, as do Xochimilco's floating gardens, but the vast water area is gone. Saline deposits make the reclaimed land unfit for agriculture, and the lake beds give Mexico City a very unstable subsoil.

Anai Peak, Hindi ANAI MUDI, peak in eastern Kerala state, southwestern India. Located in the Western Ghāts range, it rises to 8,842 feet (2,695 m) and is peninsular India's highest peak. From this point radiate three ranges—the Anaimalai to the north, the Palni to the northeast, and the Cardamom Hills to the south. Several rivers, including the Periyār and Amarāvati, rise in the surrounding ranges.

Anaimalai Hills, also called ELEPHANT MOUNTAINS, mountain range in the Western Ghāts, Tamil Nādu state, southern India. The Anaimalai Hills are a junction of the Eastern Ghāts and Western Ghāts and have a general northwest-southeast trend. Anai Peak (8,842 feet [2,695 m]) lies at the extreme southwestern end of the range and is the highest peak in southern India. Formed by fault-block movements in the Holocene Epoch, the Anaimalai Hills descend to form a series of terraces about 3,300 feet (about 1,000 m) high. Dense monsoon forests including rosewood, sandalwood, teak, and sago palm cover most of the region. The soils are mottled red and brown containing oxides of aluminum and iron and are used as building material mixed with mortar and in road construction. The Kadar, Maravar, and Pooliyar peoples inhabit the sparsely populated hills; their economy is based on hunting and gathering and on shifting cultivation. There are tea, coffee, and rubber plantations where the hills have been cleared of forests. Industries are mainly household and comprise basket weaving and the making of coir and coir mat, metal articles, and biri (cigarettes). Srīvilliputtūr, Uttamapāliyam, and Mānūr are the important towns.

anal canal, the terminal portion of the digestive tract in most animals, distinguished from the rectum because of the transition of its internal surface from a mucous membrane layer (endodermal) to one of skinlike tissue (ectodermal). In human beings the anal canal is 2.5 to 4 cm (1 to 1.5 inches) in length; its diameter is narrower than that of the rectum to which it connects. The canal is divided into three areas: the upper part, with longitudinal folds called rectal columns; the lower portion, with internal and external constrictive muscles (sphincters) to control evacuation of feces; and the anal opening itself.

The anal canal connects with the rectum at the point where it passes through a muscular pelvic diaphragm. The upper region has 5 to 10 vertical folds in the mucous membrane lining, called the anal, or rectal, columns; each column contains a small artery and vein. These are the terminal portions of the blood vessels that furnish the rectal and anal areas; they are susceptible to enlargement, commonly known as hemorrhoids. The mucous membrane of the upper portion is similar to that in the rest of the large intestine; it contains mucus-producing and absorptive cells.

The lower portions of the anal columns are joined by small concentric circular folds of the mucous membrane known as anal valves. Between the valves are small anal sinuses that open to lymph ducts and glands; these sometimes become abscessed and infected. The

internal wall of the anal canal is first lined by moist, soft skin that lacks hair or glands; it then becomes a tough (keratinized) layer of skin containing hair and glands. The keratinized layer is continuous with the skin of the anal opening and external body. Both the upper and lower portions of the anal canal have circular and longitudinal muscle layers that allow expansion and contraction of the canal. The anal opening is keratinized skin that has several folds while contracted. When open, the folds allow the skin to stretch without tearing. In the skin around the anal opening but not immediately adjacent to it are glands that give off perspiration.

The lower anal canal and the anal opening are composed of two muscular constrictions that regulate fecal passage. The internal sphincter is part of the inner surface of the canal; it is composed of concentric layers of circular muscle tissue and is not under voluntary control. The external sphincter is a layer of voluntary (striated) muscle encircling the outside wall of the anal canal and anal opening. One can cause it to expand and contract at will, except during the early years of life when it is not yet fully developed.

Waste products pass to the anal canal from the rectum. Nerve responses from the rectum cause the internal sphincter to relax while the external one contracts; shortly thereafter the external sphincter also relaxes and allows fecal discharge. The pelvic diaphragm and longitudinal muscles draw the anus and rectum up over the passing feces so that they are not extruded (prolapsed) out of the anal opening with the feces.

Nerves in the anal canal cause sphincter response and the sensation of pain. The lower part of the canal is very sensitive to heat, cold, cutting and abrasion. *See also* anus; rectum.

anal stage, in Freudian psychoanalytic theory, the period in a child's psychosexual development during which the child's main concerns are with the processes of defecation. The anal stage, generally the second and third years of life, is held to be significant for the child's later development because his responses to parental demands for bowel control may have far-reaching effects on his personality. Should a person become fixated, or locked, in the anal stage, he may develop what has been termed an anal character—orderly, frugal, and obstinate.

analcime, also called ANALCITE, common feldspathoid mineral, a hydrated sodium aluminosilicate ($\text{NaAlSi}_2\text{O}_6 \cdot \text{H}_2\text{O}$) that occurs in seams and cavities in basalt, diabase, granite, or gneiss and in extensive beds thought to have formed by precipitation from alkaline lakes. Analcime is found in Trentino, Italy; New Zealand; and Wyoming and Utah in the United States. Although a feldspathoid, analcime is closely related to the zeolite minerals with which it is sometimes classed. Its name is derived from the Greek *analkis*, "weak," which refers to the weak electrical charge generated by heating or rubbing it. For detailed physical properties, *see* feldspathoid (table).

Analects: *see* Lun yü.

analgesia, loss of sensation of pain that results from an interruption in the nervous pathway between sense organ and brain. Different forms of sensation (e.g., touch, temperature, and pain) from one area of skin travel to the spinal cord by different nerve fibres in the same nerve bundle. Hence, any injury or disease affecting such a nerve would abolish all forms of sensation in the area supplied by it. When the sensory nerves reach the spinal cord, however, their fibres separate and pursue different courses on their way upward to the brain. Thus, it is possible for certain forms of sensation to be lost, while others are preserved, in diseases that affect only certain areas in the spinal cord. Because some of the

sensations of pain and temperature travel the same path, they may be lost together. Diseases of the cord that may cause analgesia without loss of the sensation of touch are tabes dorsalis, syringomyelia, and tumours of the cord. Analgesia may also be a manifestation of hysteria. The term is also used for pain relief induced by the action of such drugs as aspirin, codeine, and morphine.

analgesic, drug that relieves pain without blocking the conduction of nerve impulses or markedly altering the function of the sensory apparatus.

A brief treatment of analgesics follows. For full treatment, *see* MACROPAEDIA: Drugs and Drug Action.

Analgesics are classified by the mechanism of their pain-relieving action as opioids (opiates and similar synthetic compounds), which act on receptors in the brain to inhibit pain impulses, or nonopioids (nonsteroidal anti-inflammatory drugs, or NSAIDs, as well as acetaminophen and phenacetin), which inhibit the synthesis of prostaglandins. Opioid analgesics may be used for either short- or long-term pain relief, though drug tolerance and physical dependence develop with prolonged use. Nonopioid analgesics are generally used for the short-term relief of mild to moderate pain and are often self-administered.

Most of the commonly used mild nonopioid analgesics are derived from three compounds, all first discovered in the 19th century: salicylic acid, pyrazolone derivatives, and phenacetin (or acetophenetidin). The most commonly used analgesic is aspirin (*q.v.*), or acetylsalicylic acid, which reduces fever and relieves inflammation, as well as lessening pain. Taken in overdose, aspirin can cause deafness, ringing in the ears, diarrhea, nausea, and headache, which disappear when the dose is reduced or stopped. Continual use of aspirin often causes irritation to the stomach wall with associated pain, nausea, vomiting, and bleeding. Aspirin and other salicylates have been linked to Reye's syndrome (*q.v.*) when used to reduce fever during viral illnesses, and thus their use to treat children is discouraged.

Of the newer NSAIDs, the most commonly used is ibuprofen, introduced in the 1970s. It shares many aspirin-like properties and has similar uses, though it causes fewer side effects and is better tolerated by most individuals.

Acetaminophen is another popular mild analgesic and antipyretic. Chemically it is a phenacetin derivative and is a suitable alternative to aspirin for patients who develop severe symptoms of stomach irritation, because it is not as harmful to the gastrointestinal tract. It does not possess equal anti-inflammatory activity, however, and so is ineffective in treating rheumatoid arthritis. Acetaminophen and similar drugs can cause kidney and liver damage if taken in overdose.

The pyrazolone analgesics (such as phenylbutazone) have effects similar to those of aspirin; they were commonly used to treat rheumatoid arthritis, but for most other applications they have been replaced by NSAIDs.

analog computer, any of a class of devices in which continuously variable physical quantities such as electrical potential, fluid pressure, or mechanical motion are represented in a way analogous to the corresponding quantities in the problem to be solved. The analog system is set up according to initial conditions and then allowed to change freely. Answers to the problem are obtained by measuring the variables in the analog model. *See also* digital computer.

The earliest analog computers were special-purpose machines, as for example the tide predictor developed in 1873 by William Thomson (later known as Lord Kelvin). Along the same lines, A.A. Michelson and S.W. Stratton built in 1898 a harmonic analyzer (*q.v.*) having 80 components. Each of these was capa-

ble of generating a sinusoidal motion, which could be multiplied by constant factors by adjustment of a fulcrum on levers. The components were added by means of springs to produce a resultant. Another milestone in the development of the modern analog computer was the invention of the so-called differential analyzer in the early 1930s by Vannevar Bush, an American electrical engineer, and his colleagues. This machine, which used mechanical integrators (gears of variable speed) to solve differential equations, was the first practical and reliable device of its kind.

Most present-day electronic analog computers operate by manipulating potential differences (voltages). Their basic component is an operational amplifier, a device whose output current is proportional to its input potential difference. By causing this output current to flow through appropriate components, further potential differences are obtained, and a wide variety of mathematical operations, including inversion, summation, differentiation, and integration, can be carried out on them. A typical electronic analog computer consists of numerous types of amplifiers, which can be connected so as to build up a mathematical expression, sometimes of great complexity and with a multitude of variables.

Analog computers are especially well suited to simulating dynamic systems; such simulations may be conducted in real time or at greatly accelerated rates, thereby allowing experimentation by repeated runs with altered variables. They have been widely used in simulations of aircraft, nuclear-power plants, and industrial chemical processes. Other major uses include analysis of hydraulic networks (e.g., flow of liquids through a sewer system) and electronics networks (e.g., performance of long-distance circuits).

analogous structure (biology): *see* analogy.

analogy (from Greek *ana logon*, "according to a ratio"), originally, a similarity in proportional relationships. It may be a similarity between two figures (e.g., triangles) that differ in scale or between two quantities, one of which, though unknown, can be calculated if its relation to the other is known to be similar to that in which two other known quantities stand. Thus, if $2:4::4:x$, it can be seen that $x = 8$. Another form of analogy noted by the Greeks is that of inferring similarity of function, known as "educing the correlate." Aristotle (*Topics*, i, 17) stated the formulas of these two kinds of analogy: "As A is to B , so C is to D "; and "As A is in B , so C is in D ."

Plato employed a functional analogy when he argued that the Idea of the Good makes knowledge possible in the intelligible world just as the Sun makes vision possible in the perceptual world. Here a relationship not yet understood is analogous to one already familiar.

In the European Middle Ages it was believed that the universe forms an ordered structure such that the macrocosmic pattern of the whole is reproduced in the microcosmic pattern of the parts so that it is possible to draw inferences by analogy from the one to the other. Thus, the law of nature conceived in the juridical sense, which prescribes the fitting order of human relationships, could be assimilated to the physical sense of law, which describes the order obtaining in the natural world. Because the natural world exhibits hierarchical degrees of subordination, it was argued, human relationships should also exhibit such subordination. Such parallels were held to constitute arguments and not merely allegorical illustrations; it was contended, for instance, that, as there were two luminaries to light the world and two authorities set over man (the papacy and the empire), then, as the Moon's light is reflected from the Sun, so the imperial authority must be derived from the papal. Dante, in his *De monarchia* (c. 1313),

while claiming that it is light and not authority that the empire derives from the papacy, nevertheless accepted the principles on which such arguments are built.

In scientific thinking, analogies or resemblances may be used to suggest hypotheses or the existence of some law or principle, especially if a comparison can be made between the functions of elements in two systems, as when observation of the moons of Jupiter suggested by analogy the modern conception of the solar system. The argument of Thomas Robert Malthus, the English economist, that populations tend to increase in numbers beyond the means of their subsistence suggested to Charles Darwin the evolutionary hypothesis of natural selection. The fruitfulness of such analogies depends on whether any testable consequences can be deduced from them, which is likely to depend on whether the resemblance is of a fundamental or a merely superficial kind. Functional resemblances are more likely to be fundamental than qualitative ones (such as colour). It would not be legitimate, for instance, to conclude from the model of the atomic nucleus as a miniature solar system that the process of nuclear fission is similar to that by which new planetary systems may be formed or disrupted.

In social and political discussion, analogies may elucidate some unfamiliar point in terms of what is more familiar. Thus, biological analogies may suggest that a community has an "organic" relationship. Such analogies are misleading, however, insofar as they overlook the fact that individual members of the community also have purposes, rights, and responsibilities of their own. In employing the method of analogy, it should always be possible to show that the resemblances noted bear relevantly on the point to be established, whereas the differences are irrelevant. In many cases it is difficult to be sure of this distinction, and arguments from analogy are therefore precarious unless supported by considerations that can be established independently.

analogy, in biology, similarity of function and superficial resemblance of structures that have different origins. For example, the wings of a fly, a moth, and a bird are analogous because they developed independently as adaptations to a common function—flying. The presence of the analogous structure, in this case the wing, does not reflect evolutionary closeness among the organisms that possess it. Analogy is one aspect of evolutionary biology and is distinct from homology (*q.v.*), the similarity of structures as a result of similar embryonic origin and development, considered strong evidence of common descent.

In many cases analogous structures, or analogues, tend to become similar in appearance by a process termed convergence. An example is the convergence of the streamlined form in the bodies of squid, shark, seal, porpoise, penguin, and ichthyosaur, animals of diverse ancestry. Physiological processes and behaviour patterns may also exhibit analogous convergence. Egg-guarding behaviour in the cobra, the stickleback, the octopus, and the spider is thought to have evolved independently among those animals, which are quite distant in their biological relationships.

Many New World cacti and African euphorbias are similar in appearance, being succulent, spiny, water-storing, and adapted to desert conditions generally. They are classified, however, in two separate and distinct families, sharing characteristics that have evolved independently in response to similar environmental challenges.

analysis, in mathematics, the extended sequence of mathematical developments that flow out of the discovery, by Sir Isaac Newton and Gottfried Wilhelm Leibniz in the late 17th century, of the differential and integral calculus. Since that time, several more or less

distinct fields of analysis have evolved, including infinite series, the calculus of variations, differential equations, Fourier analysis, complex analysis, vector and tensor analysis, and functional analysis. Other branches of mathematics have been profoundly affected by ideas originating in analysis, notably differential geometry, set theory, and topology.

A brief treatment of analysis follows. For full treatment, *see* MACROPAEDIA: Analysis (in Mathematics).

The development of the calculus introduced several ideas fateful for the subsequent history of mathematics. New techniques for calculating properties of functions—in particular their maxima and minima and the areas and volumes of plane and three-dimensional regions—made it possible for many previously difficult results to be derived routinely. Important notions of indefinitely close approximation (limits) and related techniques for arbitrarily close approximation of solutions to general equations also were introduced. Another significant idea was that of the infinite series—the expression of a quantity or function as the sum of an unending series of smaller and smaller increments. Newton and his immediate followers realized that this procedure made it possible to adapt older techniques, developed for calculations with finite polynomials, to the investigation of more general mathematical relationships.

The immediate successors of Newton and Leibniz, including the Bernoulli family and Leonhard Euler, extended the techniques of the calculus, defining the subject matter and approach that have subsequently remained standard. Euler, in particular, investigated the properties of the trigonometric, logarithmic, and exponential functions, establishing many relationships between them by manipulation of their representations as infinite series. He and the Bernoullis also extended Newton's techniques to quantities dependent upon the entire shape of a curve or surface, thereby inventing the so-called calculus of variations. These studies and Newton's use of the differential calculus to study physical motions led to an interest in differential equations, that is, relationships between functions of one or more variables and their derivatives.

Early mathematical analysts sought explicit integrals or solutions of differential equations, in terms of finite combinations of known classical functions, or, at worst, by infinite series of such terms. By the latter part of the 18th century, however, it was realized that many important problems had no explicit solutions of this type. Investigations in analysis then became more qualitative, emphasizing the derivation of useful general properties of classes of functions, rather than requiring specific formulas for them.

The calculus of functions of several variables proved useful in the study of curves and curved surfaces in space, an application pursued by Carl Friedrich Gauss, who, by applying the methods of the differential calculus to the study of geometric questions, founded differential geometry.

Early in the 19th century, J.-B.-J. Fourier showed that arbitrary functions can be represented by infinite series of sines and cosines. These series are analogous to the representation of a vector in three-dimensional space. This analogy served in the 20th century to spur the rise of functional analysis.

A.-L. Cauchy and others extended the calculus to complex functions. Cauchy showed that, if a function of a complex variable has a derivative, then its value at a given point can be expressed as an integral (Cauchy integral) of its values at other points. Cauchy's work eventually related analysis to topology, as emphasized in the work of Bernhard Riemann,

which opened themes that were adequately explored only a century later.

During the 19th century, increasing concern for logical rigour and a series of critical studies of the foundations of analysis—among which the works of Cauchy, Richard Dedekind, and Georg Cantor are particularly important—resulted in a stringent decomposition of the concept of continuity into more primitive set-theoretic notions and in the recognition that the whole structure of analysis built during the two preceding centuries could be based firmly on a handful of such principles.

The exploitation of analogies between the geometry of vectors and the properties of collections of functions has been a major theme of 20th-century analysis. David Hilbert emphasized the close relationship between certain types of equations involving integrals and linear systems of algebraic equations in several variables. Hermann Weyl showed that Hilbert's methods allowed important classes of series expansions to be derived through the study of simple differential equations. John von Neumann and Stefan Banach systematically developed this new field, called functional analysis, giving polished abstract formulations to many of its principles and techniques.

Functional analysis has led to deeper understanding of the solutions of partial differential equations important in physics and engineering. It also has revealed relationships between algebra, analysis, and topology.

analysis, in physics and chemistry, determination of the physical properties or chemical composition of samples of matter or, particularly in modern physics, of the energy and other properties of subatomic particles produced in nuclear interactions. A large body of systematic procedures intended for these purposes has been continuously evolving in close association with the development of other branches of the physical sciences since their beginnings.

A brief treatment of analysis follows. For full treatment, see *MACROPAEDIA: Analysis and Measurement, Physical and Chemical*.

Chemical analysis, in particular, has developed into a highly diversified discipline, with distinct branches oriented toward the solution of specific kinds of problems. A sample of a single compound may be analyzed to establish its elemental composition or its molecular structure; composition is most commonly found by procedures involving chemical reactions, which destroy the sample, but structure is more often studied by nondestructive measurements of physical properties. Many such measurements entail spectroscopic techniques that pinpoint the wavelengths at which electromagnetic radiation is absorbed or emitted by the substance.

Mixtures of substances are ordinarily analyzed by separating, detecting, and identifying their components by methods that depend on differences in their physical properties, such as volatility, mobility in an electric or a gravitational field, or distribution between two immiscible substances.

analytic geometry, also called *COORDINATE GEOMETRY*, the mathematical subject in which algebraic symbolism and methods are used to represent and solve problems in geometry. The importance of analytic geometry is that it establishes a correspondence between geometric curves and algebraic equations. This correspondence makes it possible to reformulate problems in geometry as equivalent problems in algebra, and vice versa; the methods of either subject can then be used to solve problems in the other.

A brief treatment of analytic geometry follows. For full treatment, see *MACROPAEDIA: Geometry: Analytic geometry*.

Many mathematicians of ancient times were aware that the geometry of figures was related to the algebra of numbers. Even the Greeks were limited, however, by the primitive state of algebraic symbolism and procedures and by their view of mathematics as being tied to and representative of the physical world. For example, the Greeks thought of ordinary numbers in terms of line segments, the product of two numbers in terms of areas, and the product of three numbers in terms of volumes. Since lengths, areas, and volumes are the only three types of geometric measurements inherent in the physical world, the Greeks were unable to consider the geometric equivalents of other types of algebraic relationships such as $y = x^4$. It was only when algebra had become a more complete and useful subject in its own right, and mathematics had moved away from a complete dependence on and relationship to the physical world, that the possibility of establishing a fruitful correspondence between geometry and algebra became evident.

Analytic geometry was established in France in the 17th century by René Descartes and Pierre de Fermat, who independently pointed out the correspondence between ordered pairs of real numbers and the distances of a point from two intersecting lines in the plane, called the axes, or coordinate axes. Once the axes are selected, every geometric point has a unique representation by an ordered pair of real numbers (x, y) and, conversely, every ordered pair of real numbers represents a unique geometric point. Modern analytic geometry employs axes that are perpendicular to each other; this type of coordinate system, and the coordinates (x, y) themselves, are called Cartesian, after René Descartes.

The correspondence established between points in a plane and ordered pairs of real numbers can easily be extended to a correspondence between points in three-dimensional space and ordered triples of real numbers (x, y, z) by using a three-dimensional Cartesian coordinate system. It is perfectly reasonable to consider and work with ordered sets of as many real numbers as is desired. Therefore, the methods of analytic geometry allow mathematicians to study the theoretical properties of spaces with dimensions greater than three, even though such spaces cannot exist in the real world. The coordinate systems developed by Descartes and Fermat are not the only ones possible; one of the most useful alternatives is the polar coordinate system developed by Sir Isaac Newton. In this system any point A in the plane can be represented by its distance r from a reference point O and by the angle θ between the half-line from O through A and a reference direction; the ordered pair (r, θ) specifies the polar coordinates of the point. Certain geometric curves have much simpler algebraic equivalents when expressed in polar coordinates than when expressed in Cartesian coordinates: an example is the logarithmic spiral. In Cartesian coordinates the equation for this curve would be

$$\frac{1}{2} \log(x^2 + y^2) = \left[\arccos \left(\frac{x}{\sqrt{x^2 + y^2}} \right) \right] \log a,$$

with a an arbitrary constant. In polar coordinates the equation is the much simpler

$$r = a^{\theta}.$$

analytic language, any language that uses specific grammatical words, or particles, rather than inflection (*q.v.*), to express syntactic relations within sentences. An analytic language is commonly identified with an isolating language (*q.v.*), since the two classes of language tend to coincide. Typical examples are Vietnamese and Classical Chinese, which are analytic and isolating. Analytic language is to be contrasted with synthetic language (*q.v.*).

Analytic philosophy, loosely related set of approaches to philosophical problems, dominant in England and the United States from

the early 20th century, that emphasizes the logical analysis of concepts and the study of language.

A brief treatment of Analytic philosophy follows. For full treatment, see *MACROPAEDIA: Philosophical Schools and Doctrines; and The History of Western Philosophy*.

Nature of Analytic philosophy. Analytic philosophers conduct conceptual investigations that characteristically (though not invariably) rely on linguistic analysis. An investigation of seeing, for example, would typically involve a systematic comparison of straightforward cases of seeing to cases in which various and sometimes subtle features of the cases are altered. By determining whether, in each case, the concept of seeing continues to apply, the investigation explores the logical boundaries of the concept and provides insight into the conditions that are necessary and sufficient for seeing to take place. Among many types of evidence that might be appealed to in the investigation are considerations of how words like "see" are used in ordinary speech. The investigation reveals not only the nature of the concept but also the underlying logical structure, or "logical form," of sentences containing "see" and related terms.

Although language has been a central area of interest to all Analytic philosophers, there have been considerable differences among them regarding the nature of so-called ordinary language and the methodological value of appeals to ordinary usage in the philosophical analysis of concepts. For many philosophers, ordinary language is potentially a source of conceptual confusion, because the surface grammatical form of a statement can sometimes mask its underlying logical form, leading to mistaken assumptions about the concepts it expresses. From this observation some Analytic philosophers, known as "formalists," draw the conclusion that, for the purposes of doing philosophy and science, ordinary language needs to be replaced or at least supplemented by precise and logically transparent formal languages based on modern symbolic, or mathematical, logic. Others, known as "informalists," reject this view, holding that attempts to "improve" ordinary language in this way inevitably oversimplify or falsify it, making it more difficult to discern underlying logical form and creating conceptual confusion of just the sort that formalists are concerned to avoid.

Moore and Russell. The birth of Analytic philosophy is traditionally dated from the early 20th century, when two of its most important figures, G.E. Moore (1873–1958) and Bertrand Russell (1872–1970), broke with the absolute Idealism that had dominated English philosophy in the last decades of the 19th century. Although both philosophers rejected Idealism, their goals and methods differed significantly, and these differences eventually gave rise to the division between the formalist and informalist traditions described above.

Moore, whose approach would inspire later philosophers in the informalist tradition, was known for his early insistence on, and careful practice of, analysis as a philosophical methodology. He became famous and controversial for his philosophy of "common sense," which was opposed to all forms of Idealism and skepticism. According to Moore, human beings know to be true many propositions about themselves and the world that are inconsistent with Idealist and skeptical doctrines. His general position was that no argument for Idealism or skepticism is as certain as the common sense view; hence, Idealism and skepticism can be rejected out of hand.

Under the influence of Moore, his Cambridge contemporary, Russell abandoned his early Idealism in favour of realism. Although sometimes criticized for frequently changing his views, Russell, whose general approach would be adopted by philosophers in the formalist tradition, consistently held that philosophical

inquiry should emulate the methods of science and that science and philosophy require the perspicuous representation of ordinary language in symbolic logic. With his colleague A.N. Whitehead, Russell was the author of the monumental *Principia Mathematica* (1910–13), which attempted to show that the whole of pure mathematics could be derived deductively from logic. Russell also solved a notorious puzzle about the nature of existence by showing, in his theory of definite descriptions, how phrases such as “The present king of France” function logically as general statements rather than as referring expressions.

Logical atomism. Along with his former pupil Ludwig Wittgenstein (1889–1951), Russell developed a metaphysical theory known as logical atomism. The name was chosen by Russell to indicate the central thesis of the doctrine, that the world contains objects that are simple, or “atomic,” and that the various arrangements of simple objects (the “facts” about the world) are mirrored in the structure of an ideal, logically perfect language. Russell’s version of logical atomism differed significantly from Wittgenstein’s, which was given its definitive expression in his *Tractatus Logico-Philosophicus* (1922; first published in German in 1921).

Logical Positivism. In the 1920s and ’30s, logical atomism exerted a powerful influence on a group of Austrian intellectuals, mostly scientists and mathematicians, known as the Vienna Circle. The doctrine developed by this group, Logical Positivism, incorporated the formalist conception of philosophy as properly scientific and grounded in logic, but it diverged from earlier theories by holding that the only sort of statement that is meaningful, or cognitively significant, is the sort made by science. On the basis of their “principle of verification,” according to which a statement is meaningful just in case it is verifiable through observation, the Positivists argued that all metaphysical, religious, and ethical pronouncements are literally nonsense. They also distinguished between what they called “analytic” statements (such as “All husbands are married”), which can be known to be true independent of any experience, and “synthetic” statements (such as “It is raining now”), which are knowable only through observation.

The later Wittgenstein. Upon completing the *Tractatus*, Wittgenstein believed that he had solved all philosophical problems, and he withdrew to a small town in Austria to teach elementary school. He later came to doubt some Tractarian doctrines, however, and he returned to Cambridge and philosophy in 1929. Eventually he came to regard the conception of language underlying the *Tractatus* as fundamentally mistaken. Among many aspects of this conception that he now rejected was the notion that the meaning of word is the particular entity it names. For the later Wittgenstein, this view is absurdly simplistic. It ignores the huge variety of ways in which words in actual languages can be meaningful, and more generally it assumes that meaning is fixed independently of the ways in which language is used. Wittgenstein now held that “the meaning of a word is its use.”

Wittgenstein’s later work on meaning and other topics—especially the relation between the mental and the physical and the nature of knowledge and certainty—was revolutionary. Although none of it was published in his lifetime, it came to exert a profound influence over almost all of Analytic philosophy in the second half of the 20th century.

Ordinary-language philosophy. Among the first to be influenced by the later Wittgenstein was a group of philosophers centred at Oxford University in the first decade after World War II. Their work, later known as “ordinary-language philosophy,” emphasized the analysis of philosophical concepts through the close examination of ordinary uses of their associated

terms. Accordingly, their investigations characteristically took the form of asking “what one would say” in various concrete situations. The most important figure in this group was John Austin (1911–60), whose speech act theory explored the various “performative” aspects of language use.

Naturalized Epistemology. With the dissemination of Wittgenstein’s oeuvre and the work of the ordinary-language school, the informalist tradition enjoyed an ascendancy in the 1950s. Nevertheless, the formalist tradition was not dormant during this period. Its most articulate spokesman after Russell, W.V.O. Quine (1908–2000), developed a systematic philosophy, called Naturalized Epistemology, that affirmed the view that symbolic logic is the proper framework for the language of philosophy and science. However, he departed from earlier formalists by rejecting the analytic-synthetic distinction and by maintaining that science can be conducted successfully without assuming the existence of any entity not definable solely in terms of logic and set theory. Quine’s work made Analytic philosophers mindful of the ontological commitments of their theories and wary of uncritically accepting the standard distinctions in their fields.

The philosophy of mind. Beginning about 1970, philosophers with formalist affinities attempted to develop Materialist accounts of the human mind as an alternative to informalist analyses based on ordinary uses of mentalistic language. The resulting theories reflected three general viewpoints: identity theory, functionalism, and eliminative materialism. According to one form of identity theory, each token of a mental state, such as a particular pain, is identical with some particular state of the brain or central nervous system. Functionalism attempted to define mental states in terms of their causal roles relative to other mental and physical states. Eliminative materialism argued that the familiar concepts of “folk psychology”—e.g., belief, desire, and intention—will soon be eliminated in favour of concepts drawn from a “mature neuroscience.”

The theory of reference. Russell’s theory of definite descriptions was used by him not only to solve the puzzle about existence mentioned above but also to account for the way in which proper names, such as “Aristotle,” refer to objects in the world. The issue was whether names refer directly or indirectly, through the mediation of meanings. Until Russell, many philosophers thought that names have referents but no meanings, and thus that reference is direct for these terms. For Russell, however, names like “Aristotle” are logically equivalent to descriptions such as “the teacher of Alexander the Great.” Thus, names do have meanings, which are the same as the meanings of their associated descriptions, and their referents are determined indirectly as whatever objects in the world (if any) the descriptions pick out.

The description account of names was prevalent until the mid 1960s, when various philosophers began to raise serious objections to it and to develop an alternative account known as the “direct-reference” theory, that returned to the view that names have referents but no meanings. They also argued that, whereas descriptions may pick out different individuals in different “possible worlds,” the individuals picked out by names remain the same in all possible worlds in which they exist. Names in this sense are “rigid designators.”

As the 20th century drew to a close, the merits of both the Russellian account and the direct-reference theory continued to be debated.

analytic psychology, the psychoanalytic method of the Swiss psychiatrist Carl Jung as he distinguished it from that of Sigmund Freud. He attached less importance than did Freud to the role of sexuality in the neuroses, and he stressed the analysis of the patient’s immediate conflicts as being more useful in un-

derstanding his problems than the uncovering of the conflicts of childhood. He defined the unconscious as including both the individual’s own unconscious and that which he inherited from his ancestors (the “collective unconscious”). He classified people into introverted and extroverted types and further distinguished them according to four primary functions of the mind—thinking, feeling, sensation, and intuition—one or more of which predominated in any given person.

anamorphosis, in the visual arts, an ingenious perspective technique used to give a distorted image of the subject represented in a picture when seen from the usual viewpoint, but so executed that if viewed from a particular angle, or reflected in a curved mirror, the distortion disappears and the image in the picture appears normal. Derived from the Greek word meaning “to transform,” the term anamorphosis was first employed in the 17th century, although this technique had been one of the more curious by-products of the discovery of perspective in the 14th and 15th centuries.

“Edward VI,” anamorphic oil portrait, 1546; in the National Portrait Gallery, London

By courtesy of the National Portrait Gallery London

The first examples appear in Leonardo da Vinci’s notebooks. It was regarded as a display of technical virtuosity, and it was included in most 16th- and 17th-century drawing manuals. Two important examples of anamorphosis are a portrait of the young Edward VI (1546; National Portrait Gallery, London) that has been attributed to Cornelis Anthonisz, and a skull in the foreground of Hans Holbein the Younger’s painting “Jean de Dinteville and Georges de Selve” (“The Ambassadors,” 1533; National Gallery, London). Many examples are provided with special peepholes through which the viewer can obtain the rectified view that first eluded him.

A modern equivalent of anamorphosis is the so-called Ames Room, in which the appearance of people and objects is distorted by manipulation of the contours of the room in which they are seen. This and other aspects of anamorphosis have received a good deal of attention in the 20th century from psychologists interested in perception.

Anan, city, Tokushima Prefecture (*ken*), Shikoku, Japan, on the Naka-gawa (Naka River), facing the Kii-suidō (Kii Channel) be-

twen the Inland Sea and the Pacific Ocean. It was created in 1958 by the merger of the former castle town of Tomioka and the fishing village of Tachibana. It is a market centre for the agricultural hinterland, and its industry produces lime, timber, ships, and wooden goods. Pop. (2004 est.) 56,803.

Anan ben David (fl. 2nd half of the 8th century), Persian Jew, founder of the Ananites, a heretical and antirabbinical order from which the still-existing Karaite sect developed.

Anan seems to have become prominent in the 760s, when he competed with his younger brother for the office of exilarch, head of the Jews of the Babylonian Exile. The office was a hereditary one, needing the confirmation of the ruling caliph, which Anan failed to obtain. He therefore declared himself antiexilarch, an action that caused him to be jailed by the civil authorities. At his trial Anan pleaded that the caliph had confirmed his brother as head of one religion but that he, Anan, had founded a new religion, one with similarities to Islām. As a result, he was released and given government protection.

In 770 Anan wrote the definitive code of his order, the *Sefer ha-mitzvot* ("Book of Precepts"). Its unifying principle is its rejection of much of the Talmud and of the rabbinic authority, which based its authority on the Talmud. Only the Bible is held to be valid, but it is interpreted with an unusual mixture of freedom and literalism.

After Anan's death, his followers settled in Jerusalem. Eventually his sect developed into the order known as Karaism (*q.v.*), which also was ascetically oriented and rejected Talmudic authority. When the State of Israel was founded in 1948, several thousand Karaites settled there.

Anand, Mulk Raj (b. Dec. 12, 1905, Peshāwar, India [now in Pakistan]—d. Sept. 28, 2004, Pune), prominent Indian author of novels, short stories, and critical essays in English, who is known for his realistic and sympathetic portrayal of the poor in India. He is considered a founder of the English-language Indian novel.

Anand, the son of a coppersmith, graduated with honours in 1924 from Punjab University in Lahore and pursued additional studies at the University of Cambridge and at University College in London. While in Europe, he became politically active in India's struggle for independence and shortly thereafter wrote a series of diverse books on aspects of South Asian culture, including *Persian Painting* (1930), *Curries and Other Indian Dishes* (1932), *The Hindu View of Art* (1933), *The Indian Theatre* (1950), and *Seven Little-Known Birds of the Inner Eye* (1978).

A prolific writer, Anand first gained wide recognition with his first novel, *Untouchable* (1935). This fictional recounting of a day in the life of a young lavatory cleaner attracted international attention with its realistic portrayal of poverty and its use of colloquial expressions. Anand continued to chronicle the indigent in such novels as *Coolie* (1936), *Two Leaves and a Bud* (1937), and *The Big Heart* (1945; rev. ed. 1980). His other major works included a trilogy—*The Village* (1939), *Across the Black Waters* (1940), and *The Sword and the Sickle* (1942)—and four volumes of *Seven Ages of Man*, a projected seven-book autobiographical novel: *Seven Summers* (1951), *Morning Face* (1968), *Confession of a Lover* (1976), and *The Bubble* (1984).

In 1945 Anand returned to Bombay (now Mumbai) to campaign for national reforms. In addition to writing both fiction and non-fiction, he edited numerous magazines and journals, including *MARG*, an art quarterly that he founded in 1946.

Ānanda (fl. 6th century BC, India), first cousin of the Buddha and one of his principal disciples, known as his "beloved disciple" and devoted companion.

Ānanda entered the order of monks in the second year of the Buddha's ministry and in the 25th year was appointed his personal attendant. According to the *Vinaya Piṭaka* texts, he persuaded the Buddha, much against the Buddha's own inclination, to allow women to become nuns. Of the Buddha's intimate disciples, Ānanda alone had not attained Enlightenment when the Buddha died. He attained it, however, just before the first council (c. 544 or 480 BC), at which he repeated the "Basket of Discourse" (*Sutta Piṭaka*). He is represented as being interlocutor in many discourses and the actual author of several. A collection of verses is ascribed to him in the *Theragāthā*. According to tradition, he lived to the age of 120 years.

ānanda (Sanskrit: "joy," or "bliss"), in Indian philosophy of the *Upaniṣads* and the school of Vedānta, an important attribute of the supreme being Brahman. Bliss is characteristically used in the *Taittirīya Upaniṣad* (c. 6th century BC) to define Brahman and, simultaneously, the highest state of the individual self. This bliss is identified with the bliss that is brought to the self by its release from the shackles of the body. In this sense *ānanda* continues to play an important role in the orthodox school of Hindu philosophy, the Vedānta, though the nature of this bliss is differently interpreted according to the views held about Brahman itself.

Ananda Bazar Patrika, morning daily Bengali-language newspaper published in Kolkata (Calcutta), one of India's largest non-English-language newspapers in terms of circulation. *Ananda Bazar Patrika* was founded in 1922 and is something of a rarity among newspapers in Indian languages, most of which do not attain circulations of more than a few thousand. The newspaper, which also publishes an Allahabad edition, rivals the country's most widely circulated daily, the English-language *Indian Express*. *Ananda Bazar Patrika's* circulation far outstrips that of the country's most influential papers, the *Times of India*, the *Statesman*, and the *Hindu*.

Ananda Mahidol, also called RAMA VIII (b. Sept. 20, 1925, Heidelberg, Ger.—d. June 9, 1946, Bangkok), eighth king of the Chakkri dynasty of Siam, whose mysterious death was one of the most traumatic events in the history of modern Thailand.

Ananda was only 10 years old and a schoolboy in Switzerland when he succeeded his uncle, King Prajadhipok, in 1935. World War II prevented his return to Thailand until 1946. Shortly thereafter, early in the morning of June 9, he was found dead in his bed of a gunshot wound. The case was never fully explained, and the controversy over it contributed to the weakening of civilian constitutional government and helped precipitate the return of military government in Thailand.

Ānandatīrtha (Hindu philosopher): see Madhva.

Ananke, in Greek literature, necessity or fate personified. In Homer the personification has not yet occurred, although even the gods admit they are limited in their freedom of action. Ananke is rather prominent in post-Homeric literature and theological speculation, particularly in the mystic cult of Orphism, but is definitely known to emerge into a cult only at Corinth, where she was worshiped with Bia ("Might," or "Force"). Because of her unalterable nature it was pointless to render to her offerings or sacrifice—"Nothing is stronger than dread Necessity" was a Greek byword.

In literature she is associated with the nymph Adrasteia, the Moirai (or Fates, of whom she

was the mother, according to Plato in *The Republic*), and similar deities. In Italy she does not appear to have been worshiped at all; the description of Necessitas (Ananke) in Horace's *Carmina* is purely literary.

Anantapur, city, southwestern Andhra Pradesh state, south-central India. The city is located 120 miles (190 km) north of Bangalore (Karnātaka state) on the Hydrābād-Bangalore main road. The city's name is derived from Ananda, the name of the wife of a dewan (official) of the medieval kingdom of Vijayanagar who built the town. Colleges of science and arts and engineering are located there. Pop. (2001) 218,808.

ānantarika-karma (Sanskrit: "the deed bringing immediate retribution"), Pāli ĀNANTARIKA-KAMMA, in the Theravāda ("Way of the Elders") tradition of Buddhism, a heinous sin that causes the agent to be reborn in hell immediately after death and never to attain Enlightenment. The sin is incurable and its retribution unavoidable. There are five sins of this kind: killing one's mother, killing one's father, killing an *arhat* (saint), injuring the body of a Buddha, and causing a division in the Buddhist community.

anapest, metrical foot consisting of two short or unstressed syllables followed by one long or stressed syllable. First found in early Spartan marching songs, anapestic metres were widely used in Greek and Latin dramatic verse, especially for the entrance and exit of the chorus. Lines composed primarily of anapestic feet, often with an additional unstressed syllable at the end of the first line, are much rarer in English verse. Because of its jog-trot rhythm, pure anapestic metre was originally used only in light or popular English verse, but after the 18th century it appeared in serious poetry. Byron used it effectively to convey a sense of excitement and galloping in "The Destruction of Sennacherib":

The Assyrian came down like a wolf on the fold,
And his cohorts were gleaming in purple and gold.

In Swinburne's "By the North Sea," however, anapestic trimeter conveys a more subdued effect:

And his hand is not weary of giving,
And the thirst of her heart is not fed.

anaphora (Greek: "a carrying up or back"), a literary or oratorical device involving the repetition of a word or phrase at the beginning of several sentences or clauses, as in the well-known passage from the Old Testament (Ecclesiastes 3:1-2) that begins:

For everything there is a season, and a time
for every matter under heaven:
a time to be born, and a time to die;
a time to plant, and a time to pluck up
what is planted; . . .

Anaphora (sometimes called epanaphora) is used most effectively for emphasis in argumentative prose and sermons and in poetry, as in these lines from Shakespeare's *Hamlet*: "to die, to sleep / To sleep—perchance to dream." It is also used to great effect in such poetry as these lines from "My Cat Jeoffry" in *Jubilate Agno*, written by an 18th-century English poet, Christopher Smart:

For I will consider my Cat Jeoffry.
For he is the servant of the Living God duly
and daily serving him.
For at the first glance of the glory of God in the
East he worships in his way.
For is this done by wreathing his body seven
times round with elegant quickness.
For then he leaps up to catch the musk, which is
the blessing of God upon his prayer. . . .

anaphylaxis, in immunology, a severe, immediate, often fatal bodily reaction to con-

tact with a foreign substance, or antigen, to which the individual has become sensitized. The condition has been extensively studied in guinea pigs, a species very liable to anaphylactic shock. The first injection of an antigen, such as egg albumin, into the body of this animal is generally harmless. A similar injection two or three weeks later has quite a different result. Within a few minutes or even seconds after reinjection, the animal sneezes, scratches its nose, becomes restless, and has great difficulty in breathing. The guinea pig may then die from asphyxia owing to its inability, in spite of violent effort, to ventilate its lungs effectively.

Anaphylaxis occurs, with varying severity, in many animals. Rats are resistant, rabbits moderately so. In humans it occurs rarely, after such events as injection of antiserum or antibiotic or after bee or wasp stings. Symptoms in humans include itching of the scalp and tongue, skin flush of the whole body, difficulty in breathing because of swelling or spasm of the bronchi, an abrupt fall in blood pressure, and unconsciousness. In milder cases, hives may spread over the whole body, and often there is a severe headache. Treatment, which must begin within a few minutes of attack, involves the injection of epinephrine (adrenaline), followed by the administration of antihistamines, cortisone, or similar drugs.

The mechanism of anaphylaxis is not fully understood but results from antigen-antibody reactions taking place on the surface of mast cells, thus damaging them and causing them to suddenly release a combination of chemicals including histamine and leukotrienes. These in turn produce the symptoms of anaphylactic shock. Anaphylaxis may occur after contact with extremely small amounts of antigen and is more common in persons with a history of atopic dermatitis.

Anápolis, town, south-central Goiás state, south-central Brazil, on the Corumbá River, 3,182 feet (970 m) above sea level. It was given city status in 1907. Today it is a rapidly growing frontier town serving a zone of pioneer settlement near an "island" of forest, the Mato Grosso de Goiás. Anápolis is a busy commercial centre with attractive squares, such as Praça Bom Jesus, and is the northwestern terminus of railroads leading inland from coastal

Praça Bom Jesus, the main square of Anápolis, Braz.

Dilson Martins

Rio de Janeiro and São Paulo. It has an airport and is also strategically situated on the highway linking Brasília, the national capital, with Goiânia, the state capital, and with São Paulo. The region's livestock, *xarque* (jerked beef), coffee, rubber, corn (maize), wheat, and minerals (rock crystals, nickel, copper, manganese, phosphate, and tin) are sent to Brazil's largest urban markets. Pop. (2000 prelim.) 279,752.

anarchism, a social philosophy whose central tenet is that human beings can live justly and harmoniously without government and that the imposition of government upon human

beings is in fact harmful and evil. Anarchists are distinguished from Marxists and other socialists in that the latter believe that the state must first be taken over before it can "wither away"; anarchists are too suspicious of the corruptions of power to believe that this is desirable or even possible.

A brief treatment of anarchism follows. For full treatment, see MACROPAEDIA: Socio-Economic Doctrines and Reform Movements, Modern.

The word *anarchism* derives from *an archos* (Greek: "without a rule"). When the word first appeared it was used as a pejorative term; the Levelers of the English Civil War and the Enragés of the French Revolution were labeled anarchists by their opponents. In 1793 William Godwin anticipated many later anarchist views in his *An Enquiry Concerning Political Justice*, although he did not use the word. Godwin not only supplied an outline of a decentralized society but also made explicit many of the theoretical assumptions involved. He insisted on the natural benevolence of individual human beings apart from governmental institutions and on the natural harmony of such individuals in their interactions. He therefore advocated the progressive breaking down of all institutions that contributed to coercion and inequality—eventually to include even marriage. Future organizations would be loose and voluntary associations.

The French writer Pierre-Joseph Proudhon adopted the word anarchism as a positive term for the first time in *Qu'est ce que la propriété?* ("What Is Property?") in 1840. Proudhon's book laid much of the theoretical groundwork for later anarchist movements, of which he is generally considered to be the father. First praised and later viciously attacked by Karl Marx, Proudhon denounced personal property ("property is theft") but rejected Communism in advocating the relative autonomy of local communities.

The various heresies that Marxism faced during the last half of the 19th century consisted chiefly of different forms of anarchism that grew out of the work of Proudhon. The earliest of these, and Marx's chief obstacle in the First International, was that of Mikhail Bakunin. Bakunin's brand of anarchism came to be called collectivism. He and his followers agreed with Marx in stressing the role of workers' associations and the need for violent revolutionary action but protested what Bakunin called Marx's German authoritarianism in favour of a looser confederation of associations. When the International disbanded in 1872, Bakunin and his followers retained control of workers' organizations in Latin countries such as Spain and Italy. It was in those countries that anarchist movements attained their greatest strength, and they were finally and decisively crushed only by the victories of Fascism just before the onset of World War II. Bakunin's emphasis on violence and revolutionary action inspired later anarchists, such as the Italian Errico Malatesta, to stress the value of violent acts as means of revealing the vulnerability of the state. A string of assassinations by anarchists took a heavy toll on world leaders around the turn of the century, including President Sadi Carnot of France (1894), Empress Elizabeth of Austria (1898), King Umberto I of Italy (1900), and President William McKinley of the United States (1901).

Not all anarchist movements were associated with violence. Many forms, such as that developed by Proudhon and known as Mutualism, rejected revolutionary activity; certain of Proudhon's followers even rejected strikes as a tactic, since they represented a form of coercion. The form of anarchism to attract the largest following was known as anarcho-syndicalism, which developed in the late 1880s after the crushing of the Paris Commune. Anarcho-syndicalism combined the anarchists' distrust

of political action with the tactics of the trade union movement; the labour *syndicats* were to become the basis for direct action by the working class, to culminate in a general strike that would paralyze the economy and the state. Anarcho-syndicalism generated a mystique of the working class instead of the mystique of the individual that was characteristic of other forms of anarchism.

Owing to their repudiation of political action and to their vision of a just and harmonious society of individuals linked only by voluntary associations, many anarchist thinkers tended to take a high moral tone; notable among them was Peter Kropotkin. Anarchism as a social movement did not survive World War II. Nevertheless, some of its tenets, such as that human beings can be naturally moral and complete without governments, continue to attract followers.

Anarcho-Syndicalism: see Syndicalism.

anasarca, also called **DROPSY**, a severe, generalized form of edema (*q.v.*).

Articles are alphabetized word by word, not letter by letter

Anasazi culture, a North American civilization that developed from about AD 100 to modern times, centring generally on the area where the boundaries of Arizona, New Mexico, Colorado, and Utah intersect. (*Anasazi* is Navajo for "Ancient Ones.") It is customarily divided into these developmental periods: Basket Maker period, 100–500; Modified Basket Maker period, 500–700; Developmental Pueblo period (formerly designated Pueblo I and II), 700–1050; Classic Pueblo (formerly designated Pueblo III), 1050–1300; Regressive Pueblo (formerly designated Pueblo IV), 1300–1700; and Modern Pueblo (formerly designated Pueblo V), 1700 to date.

The origin of the Basket Maker Indians is not known, but it is evident that, when they first settled in the area, they were already excellent basket weavers and that they were supplementing hunting and wild-seed gathering with the cultivation of maize and pumpkins. They lived either in caves or out in the open in shelters constructed of a masonry of poles and adobe mud. Both caves and houses contained special pits, often roofed over, that were used for food storage.

This basic pattern continued into the period of the Modified Basket Makers, when agriculture became their major interest (bean crops were added and turkeys were domesticated) and hunting and gathering were reduced to supplementary roles. Villages remained either in caves or out in the open; but those in caves consisted of an array of semisubterranean houses, and those in the open consisted of chambers both aboveground and belowground, all often contiguously joined in straight lines or crescents. Aboveground chambers probably served as storage places and the pit houses as domiciles and ceremonial rooms. These pit houses were actually elaborations of the old storage pits. Sun-dried pottery was introduced during this period.

During the Developmental Pueblo period, the same type of straight-line or crescent-shaped multiple house was built, but gradually enlarged. Stone masonry, too, began to replace the earlier pole-and-mud construction. The pit houses became kivas, the underground circular chambers used henceforth primarily for ceremonial purposes. Aboveground chambers were used wholly as domiciles. Agriculture may have been augmented at this time by the cultivation of cotton. Pottery assumed a greater variety of shapes, finishes, and decorations. Basketry was less-common. Throughout

the period the area of occupation continued to expand.

The Classic Pueblo period was the time of the great cliff houses, the villages built in sheltered recesses in the faces of cliffs but otherwise differing little from the masonry or adobe houses and villages built elsewhere. This was also the time of the large, freestanding, apartment-like structures built along canyons or mesa walls. In either locale, many dwellings consisted of two, three, or even four stories, often built in stepped-back fashion so that the roofs of the lower rooms served as porches for the rooms above. These community structures had from 20 to as many as 1,000 rooms. An actual shrinking of the inhabited areas took place as people of the outer fringes moved in to build the large units. Craftsmanship in pottery reached a high level, and cotton and yucca fibre were skillfully woven.

Abandonment of the cliff houses and large community dwellings marked the close of the Classic Pueblo period. In part this may have resulted from the incursion of nomadic Navajo and Apache from the north and a prolonged drought that occurred from 1276 to 1299.

The Regressive Pueblo period was characterized by movement of the people south and east, some to the Rio Grande valley or the White Mountains of Arizona. New villages, some larger than those of Classic Pueblo, were built but were generally poorer and cruder in layout and construction (sometimes walls consisted wholly of adobe). Fine pottery making still flourished, however, though changed in design, and weaving continued as before.

The Modern Pueblo period is usually dated from about 1700, when Spanish influences first began to be pervasive. Official Spanish occupancy of the area had begun in 1598, but the Spaniards' attempts at forced religious conversions and tribute caused hostility among the Indians, leading in 1680 to open revolt and the killing or expulsion of the Spaniards. Not until about 1694 was Spanish authority reimposed. A century of unsettled conditions, however, had reduced the number of Pueblo settlements from about 70 or 80 to 25 or 30. Much of the culture and many of the skills in agriculture and crafts, nevertheless, have continued down to modern times.

Anastasia, Russian in full ANASTASIYA NIKOLAYEVNA (b. June 18 [June 5, Old Style], 1901, Peterhof [now Petrodvorets], near St. Petersburg, Russia—d. July 16/17, 1918, Yekaterinburg), grand duchess of Russia and the youngest daughter of Tsar Nicholas II, last emperor of Russia.

Anastasia was killed with the other members of her immediate family in a cellar where they had been confined by the Bolsheviks following the October Revolution. But after the executions several women outside Russia claimed her identity, making her the subject of periodic popular conjecture and publicity. Each claimed to have survived the execution and managed to escape from Russia, and some claimed to be heir to the Romanov fortune held in Swiss banks. Perhaps the most famous of these claimants was a woman who called herself Anna Anderson (and whom critics alleged to be one Franziska Schanzkowska, a Pole), who married an American history professor, J.E. Manahan, in 1968 and lived her final years in Virginia, U.S., dying in 1984. In the years up to 1970 she sought to be established as the legal heir to the Romanov fortune; but, in that year, West German courts finally rejected her suit and awarded a remaining portion of the imperial fortune to the duchess of Mecklenburg. In the 1990s, genetic tests undertaken on tissues from Anderson and on the exhumed remains of the royal family established no connection between her

and the Romanovs and instead supported her identification with Schanzkowska.

The story of a surviving Anastasia provided the germ of a French play, *Anastasia*, written by Marcelle-Maurette (1909–72) and first produced in 1954. An American film version appeared in 1956, with Ingrid Bergman winning an Academy Award for her title role.

Anastasia, Albert, original name UMBERTO ANASTASIO (b. Sept. 26, 1902, Tropea, Italy—d. Oct. 25, 1957, New York, N.Y., U.S.), major American gangster.

Anastasia immigrated to New York City from Italy in 1919 and, in the 1920s, rose through Giuseppe Masseria's gang. He was one of Masseria's executioners in 1931, at Lucky Luciano's command. In the late 1930s he became active head of "Murder, Inc.," a notorious murder-for-hire organization, and in the late 1940s became boss of one of the Five Families of organized crime in New York City. He was murdered by two gunmen (hired by rival Vito Genovese) as he sat in a barber chair in the Park Sheraton Hotel.

Anastasius, Greek ANASTASIOS, name of rulers grouped below by country or papacy and indicated by the symbol •.

BYZANTINE EMPIRE

• **Anastasius I** (b. 430?, Dyrrhachium, Epirus Vetus [now Durrës, Albania]—d. July 9, 518, Constantinople [now Istanbul, Turkey]), Byzantine emperor from 491 who perfected the empire's monetary system, increased its treasury, and proved himself an able administrator of domestic and foreign affairs. His heretical monophysite religious policies, however, caused periodic rebellions.

After serving as an administrator in the department of finance and as a personal bodyguard to the emperor Zeno, Anastasius was chosen at the age of 61 to be emperor by his predecessor's widow, Ariadne, who married him shortly thereafter. He began his rule by abolishing the sale of offices, reforming taxation, and refusing rewards to informers.

Among the first actions of Anastasius was the expulsion of Zeno's rebellious and powerful countrymen, the Isaurians, from Constantinople and their later resettlement in Thrace. To protect Constantinople against the raiding Bulgarians and Slavs, Anastasius built a wall (512) from the Black Sea to the Sea of Marmara. In foreign affairs he recognized Theodoric's Ostrogoth rule in Italy (497), but the two rulers were soon in opposition, Anastasius sending a fleet to ravage the Italian coast (508). Meanwhile, war with Persia erupted in 502, when Anastasius refused to pay a share for the defense of the Caucasian Gates, a pass through which nomadic tribes often raided Persia and Byzantium. After the Persians attacked, Anastasius built forts to secure his eastern frontier. The status quo was restored when peace was concluded in 505, with Anastasius agreeing to payments to the Persian king.

At first professing orthodoxy, Anastasius gradually adhered more to monophysite doctrine, which held that Christ had one, divine nature. Although this stand caused great unrest in Constantinople and in the European provinces, it did buy peace with Egypt and Syria. In Thrace, however, it inspired rebellion by the military commander Vitalianus, who revolted twice, withdrawing each time after being promised satisfaction; when he attacked a third time, he was defeated (515).

Anastasius was succeeded by the 70-year-old Justin I, commander of the guard and uncle of his illustrious successor, Justinian.

• **Anastasius II**, original name ARTEMIS (d. 721), Byzantine emperor from 713 to 715.

He was chosen to take the throne after an army coup deposed Philippicus, whose secretary he had been. Anastasius reversed the ecclesiastical policies of Philippicus and tried to

reform the army before he, too, was deposed. Assuring Pope Constantine of his orthodoxy, Anastasius withdrew Philippicus' monothelitic decrees, which had imposed the heretical doctrine of a single will of Christ. Militarily, he fortified Constantinople, selected the island of Rhodes as a Byzantine naval base, and sent the Isaurian Leo, the future emperor Leo III, to defend Syria against the Arabs. In the meantime, troops in the Opsikian province rebelled and proclaimed as emperor Theodosius, a local tax collector, who was seated (715) in Constantinople after a six-month civil war. Anastasius fled and became a monk in Thessalonica in 716. Failing in an attempt to regain his throne in 720, he was executed by Theodosius' successor, Leo III.

PAPACY

• **Anastasius I, SAINT** (b. Rome?—d. Dec. 19, 401, Rome [Italy]; feast day December 19), pope from Nov. 27, 399, to 401, succeeding Pope Siricius.

Anastasius earned the praise of St. Jerome (Letter 127) for censuring (c. 400) the works of Origen, one of the most influential theologians of the early Greek church. In papal letters he condemned several Origenist writings and disapproved the spreading of Origen's teaching. Anastasius' virtues were praised by his admirers Saints Augustine of Hippo, Jerome, and Paulinus of Nola.

• **Anastasius II** (b. Rome [Italy]—d. Nov. 19, 498, Rome), pope from Nov. 24, 496, to 498.

In notifying the Byzantine emperor Anastasius I of his accession, Anastasius expressed a conciliatory attitude toward the late patriarch Acacius of Constantinople, who had been deposed and excommunicated in 484 by Pope St. Felix III. The Acacian Schism resulted from this act. The pope's reception of the Byzantine deacon Photinus, sent to Rome by a supporter of Acacius, was followed by a schism at Rome and the charge that the pope desired to rehabilitate Acacius. Anastasius died in the midst of the controversy.

A confused tradition blamed Anastasius for being led by Photinus into heretical opinions concerning the divinity of Jesus Christ. Dante (*Inferno* XI, 8) placed him among the heretics in the sixth circle of hell.

• **Anastasius III** (b. Rome [Italy]—d. June or August 913, Rome), pope from April or June 911 to 913. Because his pontificate came during a period when Rome was under the control of the house of Theophylactus, he had little authority or freedom of action.

• **Anastasius IV**, original name CORRADO DI SUBURRA (b. c. 1073, Rome [Italy]—d. Dec. 3, 1154), pope from July 1153 to December 1154.

As cardinal bishop of Sabina, he had staunchly supported Pope Innocent II in 1130, serving as his vicar in Rome during the contest with the antipope Anacletus II. During his brief pontificate he was a peacemaker noted especially for settling two long-standing problems: one regarding Emperor Frederick I Barbarossa and the see of Magdeburg, the other regarding St. William of York and his see.

Anastasius THE LIBRARIAN, Latin ANASTASIUS BIBLIOTHECARIUS (b. c. 810, probably Rome [Italy]—d. c. 878), language scholar, Roman cardinal, and influential political counselor to 9th-century popes.

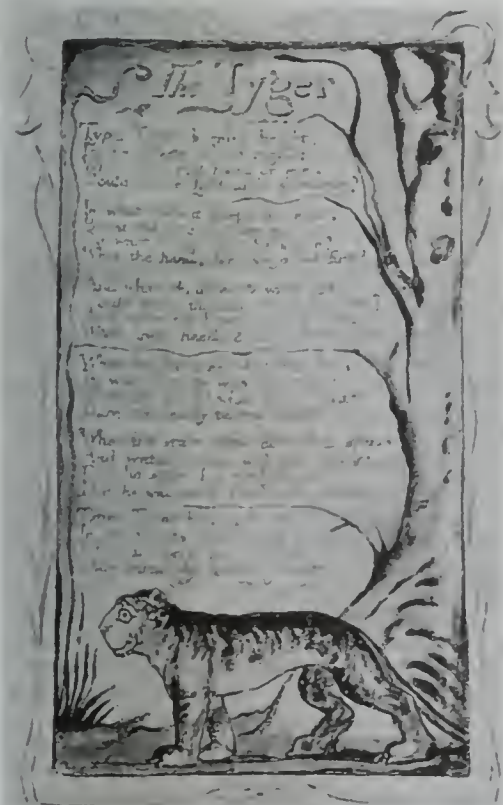

Related to an Italian bishop, Anastasius became cardinal priest of the Church of St. Marcellus, Rome, about 848, after gaining prominence as a Greek scholar. Deposed in 853 because of political activity, he stood for a short time as antipope to Benedict III (855–858). After a reconciliation Anastasius became papal librarian and disputed with the Greek Orthodox theologian Photius, patriarch

of Constantinople (858–867; 878–886), over the question of the Holy Spirit's relationship within the Christian Trinity, a controversy crucial to Eastern and Western doctrinal differences leading to open schism.

Exhibiting thorough efficiency in expressing the ideas of the papacy, Anastasius maintained the post of librarian under Popes Adrian II (867–872) and John VIII (872–882). On the visit of Saints Cyril and Methodius to Rome, he supported their Christianizing mission among the Slavic peoples and their development of a native liturgy. Representing the Holy Roman emperor, the Frank Louis II (c. 824–875), Anastasius undertook a diplomatic mission to the Byzantine emperor Basil I (867–886) in an unsuccessful attempt to arrange a marriage between the two dynasties. He remained in Constantinople nevertheless to assist at the eighth general council of 869–870, which achieved final doctrinal formulations concerning the Trinity, emphasizing the divinity of the Holy Spirit and condemning Photian teaching. Anastasius' Latin translations of the council's proceedings and compilation of other documents relating to the monothelism controversy (see Monothelism) contributed to the history of Western theology. A later Latin collection also incorporated his "Threepart Chronicle" of Byzantine history from the 6th to the 9th century.

Included in Anastasius' major writings are commentaries on the influential 6th-century Neoplatonic philosopher Pseudo-Dionysius the Areopagite and probably the accounts of Popes Nicholas I and Adrian II in the *Liber pontificalis* (Latin: "The Book of the Popes"), an essential source for the history of primitive Christianity.

anastatic printing, also called RELIEF ETCHING, a technique of printmaking from a plate on which all but the design to be printed is etched away, leaving the design in relief. In zinc etching, the most popular anastatic process, the design is painted on a zinc plate in asphalt varnish and the uncoated portions of the plate are bitten away by a solution. The process is best known as that in which the English poet and artist William Blake executed the text and illustrations of many of his books.

"The Tyger," anastatic print by William Blake, 1794, from *Songs of Innocence and of Experience*. Showing the Two Contrary States of the Human Soul

Anat (goddess): see Anath.

anatase, one of three minerals composed of titanium dioxide (TiO₂), the other two being rutile and brookite. It is found as hard, brilliant crystals of tetragonal symmetry and various colours in veins in igneous and metamorphic rocks and commonly in placer deposits of detritus. Notable vein deposits exist in many regions of the Alps; placer deposits are common in Minas Gerais and Bahia, Brazil. Much anatase is formed by weathering of titanite, and it is itself altered to rutile; rutile paramorphs (replacements having the same outward shape) after anatase are common in the detrital deposits of Brazil and the Sanarka region of the Urals. For detailed physical properties, see oxide mineral (table).

anatexis, in geology, the differential, or partial, melting of rocks. Each mineral in a rock has its own melting temperature, which is decreased to varying degrees by its close association with other minerals. In addition to the melting temperature of each individual mineral, pressure, temperature, and the presence of volatiles all influence the melting temperature of a mineral assemblage; a rock has a melting range dependent upon these parameters. In the process of anatexis, it is assumed that rocks are buried to such great depths that an increase of pressure and temperature causes partial melting; as the temperature is increased, an increasing percentage of the rock becomes liquid. The rock fraction with the lowest melting range typically has a granitic composition, and the unmelted residuum is more basic (silica-poor). The layers of granite in migmatites, and perhaps larger granitic bodies, may have formed through anatexis.

Consult the INDEX first

Anath, also spelled ANAT, chief West Semitic goddess of love and war, the sister and helpmate of the god Baal.

Considered a beautiful young girl, she was often designated "the Virgin" in ancient texts. Probably one of the best known of the Canaanite deities, she was famous for her youthful vigour and ferocity in battle; in that respect she was adopted as a special favourite by the Egyptian king Ramses II (reigned 1279–13 BC). Although Anath was often associated with the god Resheph in ritual texts, she was primarily known for her role in the myth of Baal's death and resurrection, in which she mourned and searched for him and finally helped to retrieve him from the netherworld.

Egyptian representations of Anath show a nude goddess, often standing on a lion and holding flowers. During the Hellenistic Age, the goddesses Anath and Astarte (*q.v.*) were blended into one deity, called Atargatis (*q.v.*).

anathema (from Greek *anathēnai*: "to set up," or "to dedicate"), in the Old Testament, a creature or object set apart for sacrificial offering. Its return to profane use was strictly banned, and such objects, destined for destruction, thus became effectively accursed as well as consecrated. Old Testament descriptions of religious wars call both the enemy and their besieged city anathema inasmuch as they were destined for destruction.

In New Testament usage a different meaning developed. St. Paul used the word anathema to signify a curse and the forced expulsion of one from the community of Christians. In AD 431 St. Cyril of Alexandria pronounced his 12 anathemas against the heretic Nestorius. In the 6th century anathema came to mean the severest form of excommunication that formally separated a heretic completely from the Christian church and condemned his doctrines; minor excommunications, while prohibiting free reception of the sacraments, obliged (and permitted) the sinner to rec-

tify his sinful state through the sacrament of penance.

Anatidae, bird family that includes ducks, geese, and swans; it constitutes the suborder Anseres—by far the larger part of the order Anseriformes.

A widely accepted system of classification divides the Anatidae into 3 subfamilies and 8 to 12 tribes, as follows:

Anseranatinae—tribe Anseranatini (see magpie goose).

Anserinae—tribes Dendrocygnini (see whistling duck, or tree duck) and Anserini (see goose; swan). A third tribe, Stictonettini, has been proposed (see freckled duck).

Anatinae—tribes Tadornini (see sheldgoose; shelduck), Anatini (see dabbling duck), Cairinini (see perching duck), Aythyini (see pochard), Somateriini and Mergini (see diving duck), and Oxyurini (see stiff-tail). Some authorities include the eiders (Somateriini) in the Mergini; some separate a tribe Tachyerini from the Tadornini; and some recognize a tribe Merganettini (see torrent duck) aside from the Anatini. The Aythyini, Somateriini, Mergini, and (from one standpoint) the Oxyurini (pochard, diving duck, and stiff-tail) are often considered together in popular usage.

An older division of the family appeared in several field books in wide use in the United States and Europe in the late 1960s. It assigned the Anatidae into the following main subfamilies (without tribes): Cygnae, swans; Anserinae, true geese; Dendrocygnae, whistling ducks; Anatinae, dabbling ducks, including shelducks and perching ducks; Nyrocinae (or Aythyinae), diving ducks other than mergansers; Erismaturinae (or Oxyurinae), stiff-tails; and Merginae, mergansers.

anatman (Indian philosophy): see anatta.

Anatolia, Turkish ANADOLU, also called ASIA MINOR, the peninsula of land that today constitutes the Asiatic portion of Turkey. Because of its location at the point where the continents of Asia and Europe meet, Anatolia was, from the beginnings of civilization, a crossroads for numerous peoples migrating or conquering from either continent.

A brief treatment of the history of Anatolia follows. For full treatment, see MACROPAEDIA: Turkey and Ancient Anatolia.

Anatolia has been known from the earliest period as a battleground between the East and the West. The central plateau, with no navigable rivers and few natural approaches, its monotonous scenery, and severe climate, is a continuation of Central Asia. The western coast, with its fertile valleys and fine climate, is almost a part of Europe. These conditions are unfavourable to permanence, and the history of Anatolia is that of the march of nomad tribes and colonists and of the rise and fall of small states.

About 1950 BC western Anatolia appears to have been held by the 1st dynasty of Hittites. Two centuries later, Aryan races seem to have invaded the country and imposed at least their language on the Hittites, who in the 17th century BC emerged suddenly as a powerful empire at Hattusa (modern Boğazköy), ruling over Anatolia and fighting the Egyptian pharaohs for the mastery of Syria, and Assyria for the mastery of Mittani (Jerablus).

This Hittite empire was overthrown by Indo-European races, possibly Greeks, who, crossing the Hellespont from Europe to Asia, with their iron weapons defeated the Hittites, who possessed only bronze weapons. These Indo-European races established many colonies all along the Aegean coast and in the hinterland, from which arose the Phrygian kingdom. Traces of this kingdom remain in various rock

tombs, forts, and towns and in legends preserved by the Greeks. In the 8th century BC the Cimmerians coming from Armenia overran the Phrygian kingdom, and on its decline rose the kingdom of Lydia, with its centre at Sardis. A second Cimmerian invasion, followed later by Cyaxares, almost destroyed the rising kingdom, but the invaders were stopped by Alyattes (c. 617–560 BC). The last king, Croesus (560–546 BC), carried his boundaries to the Halys and subdued the Greek colonies on the coast. These flourishing Greek colonies formed a chain of settlements extending from Trebizond to Rhodes. Too jealous of each other to combine and too demoralized by luxury to resist, they fell an easy prey to Lydia. After the capture of Sardis by the Persian Cyrus II the Great (c. 546 BC), these colonies passed to Persia without resistance. Under Persian rule, Anatolia was divided into four satrapies, but the Greek cities were governed by Greeks, and the tribes in the interior retained their native princes and priest-dynasts. Beginning with Darius' attempt to conquer the European, as well as the Asiatic, Greeks, the Greco-Persian Wars ended in 334 BC, when Anatolia was invaded by Alexander the Great.

After the death of Alexander, various *diadochoi* (succession rulers) established their rule over various parts of the peninsula. Rhodes became a great maritime republic. The Ptolemies of Egypt ruled over the Mediterranean coast of Anatolia. A small independent kingdom was founded at Pergamum in 283 BC and lasted a century and a half. Bithynia became an independent monarchy, Cappadocia and Paphlagonia tributary provinces under native princes. In the south, the Seleucids founded Antioch, Apamea, Attalia, the Laodiceas, and other cities as centres of commerce, some of which afterwards played an important part in the Hellenization of the country and in the spread of Christianity. During the 3rd century BC, certain Celtic tribes crossed the Bosphorus and established their power in districts between the Sangarius and Halys, called Galatia. Its capital was at Ancyra—the modern Ankara, the capital of republican Turkey.

The defeat of Antiochus the Great at Magnesia (190 BC) placed Anatolia at the mercy of Rome, but it was only in 133 BC that the first Roman province, Asia, was formed to include western Anatolia. Under Mithradates the Great, Pontus rose into a formidable power; but he was driven from his country by Pompey the Great and died in 63 BC. The Romans organized the peninsula into various provinces, leagues, and almost independent principalities, and under their dominion Anatolia, or Asia Minor, developed and became prosperous. At the end of the 3rd century AD, in reorganizing the empire, Diocletian broke the great military commands and united the provinces into groups called dioceses. A great change followed the introduction of Christianity, which gradually spread over the region.

When the Roman Empire was divided in two in 395, Anatolia fell to the Eastern Roman Empire with its capital at Constantinople; the native languages and old religions partly disappeared, and the country was thoroughly Hellenized. At the close of the 6th century, Anatolia had become wealthy and prosperous, but centuries of peace and overcentralization produced a state of affairs that is embodied in the term Byzantine. The vigorous Persian monarch Khosrow II invaded Anatolia from 616 to 626 and pitched his camp on the Bosphorus. The emperor Heraclius, however, restored the Byzantine power by marching his army to Kurdistan; but soon after, the Arabs entered Anatolia and in AD 668 laid siege to Constantinople. For the following three centuries, Byzantium and the caliphs of Baghdad waged occasional warfare for the mastery of

the bridgeheads of the Euphrates and the Cilician gates. But a more dangerous enemy was soon to appear from the East. In 1067 the Seljuq Turks ravaged Cilicia and Cappadocia; in 1071 they defeated and captured the emperor Romanus Diogenes; in 1080 they took Nicaea. One branch of the Seljuqs founded the empire of Rum with its capital at Iconium. During the 12th century, a number of Seljuq Atabeks ruled in different districts of Anatolia; the Mamluks of Egypt in Syria and farther east; Greeks in Pontus; Armenians in Cilicia; Danishmends (an Armenian family) at Sivas; Bayandurs (a Greek family) at Erzerum; etc. The Mongols swept the whole region and in 1243 subdued the Seljuq sultan of Rum. In the ensuing struggle for power among the Turkish tribes, the Ottoman Turks eventually assumed supremacy and established their state at Brusa. In 1400 Sultan Bayezid I held almost all Anatolia west of the Euphrates. But he was defeated and imprisoned by Timur, who swept through the country to the shores of the Aegean. On the death of Timur, the Ottoman power was reestablished after a prolonged struggle that ended with the annexation by Mehmed II (1451–81) of Karamania and Pontus.

The Seljuq hordes who had devastated Anatolia in the 11th century had been followed by a long succession of nomad Turkish tribes who left the country bare and desolate. Subsequently, nearly all traces of Hellenic civilization disappeared with the enforced use of the Turkish language and wholesale conversions to Islam under the early Ottoman sultans.

The later history of Anatolia is that of the Ottoman Empire. The Turks dominated Anatolia until their rule was shattered in World War I. The Treaty of Sèvres, signed by the defeated Turks and the victorious Allies in 1920, abolished the Ottoman Empire, but the treaty's territorial concessions in Anatolia to the Allies and their Greek and Armenian clients were rejected by the Turkish nationalist movement led by Mustafa Kemal (afterward Atatürk), and the Treaty of Lausanne in 1923 left Turkey sovereign in all of Anatolia. Under Allied auspices and in conjunction with the Treaty of Lausanne, a convention for the exchange of populations was signed between Turkey and Greece by which about 1,000,000 Greeks were transferred from Anatolia to Greece.

Anatolian languages, the extinct Indo-European and non-Indo-European languages spoken in Anatolia from sometime in the 3rd millennium BC until the early centuries of the present era, when they were gradually supplanted by Greek. They include the Indo-European languages Hittite, Palaic, Luwian, Hieroglyphic Luwian, Lydian, Lycian, and Phrygian and the non-Indo-European languages Hattic, Hurrian, and Urartian. Two other Anatolian languages, Carian and Sidetic, are so poorly attested that whether or not they are Indo-European is unknown. Anatolian is also used in a narrow sense to refer to the languages that belong to the Anatolian branch of Indo-European. This branch includes all of the Indo-European languages listed above with the exception of Phrygian. The non-Indo-European languages of Anatolia are sometimes called Asianic.

A brief treatment of the Anatolian languages follows. For full treatment, see *MACROPAEDIA: Languages of the World*.

Hittite is the best attested of the Anatolian languages. It is known chiefly from approximately 25,000 clay tablets or fragments of tablets that were excavated at Boğazköy-Hattusa, the Hittite capital, in central Anatolia. It was written in a cuneiform script that closely resembles that used in the 17th century BC in Alalakh. The language was first shown to be Indo-European in 1902 by a Norwegian Assyriologist, Jørgen Alexander Knudtzon, who

based his study on two Hittite letters that had been found in the Amarna archive. Hittite was first interpreted in 1915 by a Czech Orientalist, Bedřich Hrozný, who worked with the tablets excavated at Boğazköy. The majority of the Hittite texts are concerned with religious subjects (oracle texts, hymns, prayers, myths, rituals, and festival texts), but there are also many of historical, political, administrative, literary, and legal character.

Palaic was used as a ritual language in a few Hittite cuneiform texts. It was spoken in Pala (probably Blaëne in the Greek period) in northwest Anatolia. It is closely related to Hittite and Luwian, but very little else is known about it because it is so poorly attested.

Luwian was spoken in southern Anatolia and northern Syria. It is known from texts of three major periods: the Hittite New Empire (c. 1400–c. 1190 BC) found at Boğazköy-Hattusa; the period of the Neo-Hittite states (c. 1190–c. 700 BC); and monumental inscriptions of about 400 to about 200 BC. Hieroglyphic Luwian is the daughter language of the East Luwian dialect, while Lycian is a later descendant of a West Luwian dialect.

The Anatolian hieroglyphic system begins as early as the Hittite stamp seals of the 18th and 17th centuries BC; the youngest texts date from approximately the last quarter of the 8th century BC. Geographically they are attested across southern Anatolia well into northern Syria and as far north as the Hittite capital, Boğazköy-Hattusa. The decipherment of Hieroglyphic Luwian was accomplished during the 1930s and '40s. Significant contributions were made by the British archaeologist Archibald H. Sayce, the German-born Orientalist Hans G. Güterbock, and the German archaeologist Helmuth T. Bossert.

Lydian is attested in sepulchral inscriptions, votive texts, and many graffiti, the majority of which were excavated at the Lydian capital, Sardis. Most stem from the 4th century BC. The Lydian alphabet was derived from an East Greek prototype. The study of Lydian is hampered by many lexicological uncertainties, but the grammar indicates that it belongs to the Anatolian subgroup of Indo-European.

The Anatolian branch of Indo-European contains numerous grammatical archaisms combined with the absence of several typical Indo-European categories such as the dual number, the feminine gender, and the perfect tense. Another peculiarity is a strong preference for the linking of particles and enclitic pronouns to form "chains" that are placed at the beginning of a sentence or clause. A striking phonological trait is the presence of certain guttural sounds (laryngeals) not found in the other Indo-European languages.

Phrygian is the one Indo-European language of Anatolia that does not belong to the Anatolian subgroup. The Phrygian inscriptions and graffiti may be separated into two groups: Old Phrygian texts in a typical Phrygian alphabet dating from about 730 to 450 BC, and New Phrygian inscriptions (sepulchral texts in the Greek alphabet) from the 1st and 2nd centuries AD.

Hattic is known from its ritual use in the Hittite cuneiform texts. It was the linguistic substratum of northern Anatolia before the invasion of the Indo-European speakers. Hattic has no known relatives.

Hurrian texts have been found in Urkish (c. 2300 BC), Mari (18th century BC), Amarna (c. 1400 BC), Boğazköy-Hattusa (c. 1400–c. 1190 BC), and Ugarit (14th century BC). All of these texts are in cuneiform, with the exception of several that are in the Ugaritic alphabetic script. The many Hurrian personal names found at Boğazköy-Hattusa, Alalakh, Ugarit, and especially Nuzu constitute a second important source of information about this language.

Urartian was used in northeastern Anatolia during the 9th through the 6th century BC as

the official language of Urartu. The Urartian texts are written in a variant of the Neo-Assyrian cuneiform script. There is also an indigenous hieroglyphic script that is poorly attested and remains undeciphered. Hurrian and Urartian share a common parent language. They are agglutinative and chiefly suffixing.

Carian is attested mainly by graffiti found in Egypt that were written in an alphabetic script by Carian mercenaries, but it is also attested by monumental inscriptions and clay tablets found in Caria itself. The assumption that Carian belongs to the Anatolian branch of Indo-European is still unproved.

Sidetic was spoken in the city of Side on the Pamphylian coast. It is attested by legends on coins of the 5th(?) through the 3rd(?) century BC and by five inscriptions from the 3rd and 2nd centuries BC, two of which are bilingual. The script is only partly deciphered, so nothing is known about the contents of the texts or the classification of the language.

Anatom, also spelled ANEITYUM, southernmost island of Vanuatu, in the southwestern Pacific Ocean. Volcanic in origin, it has a circumference of 35 miles (56 km) and an area of 25 square miles (65 square km) and rises from a fertile coastal plain and valleys to a height of 2,795 feet (852 m). Anatom was a centre of sandalwooders, whalers, and missionaries in the New Hebrides in the 19th century; its valuable stands of kauri pine were once exploited. Anelgauhat is a good harbour on the south coast, with an airstrip on nearby Inyeug Island. Pop. (1989) 361.

anatomy, a field in the biological sciences concerned with the identification and description of the body structures of living things. Gross anatomy involves the study of major body structures by dissection and observation and in its narrowest sense is concerned only with the human body. "Gross anatomy" customarily refers to the study of those body structures large enough to be examined without the help of magnifying devices, while microscopic anatomy is concerned with the study of structural units small enough to be seen only with a light microscope. Dissection is basic to all anatomical research. The earliest record of its use was made by the Greeks, and Theophrastus called dissection "anatomy," from *ana temnein*, meaning "to cut up."

Comparative anatomy, the other major subdivision of the field, compares similar body structures in different species of animals in order to understand the adaptive changes they have undergone in the course of evolution. (See comparative anatomy.)

Gross anatomy. This ancient discipline reached its culmination between 1500 and 1850, by which time its subject matter was firmly established. None of the world's oldest civilizations dissected a human body, which most people regarded with superstitious awe and associated with the spirit of the departed soul. Beliefs in life after death and a disquieting uncertainty concerning the possibility of bodily resurrection further inhibited systematic study. Nevertheless, knowledge of the body was acquired by treating wounds, aiding in childbirth, and setting broken limbs. The field remained speculative rather than descriptive, though, until the achievements of the Alexandrian medical school and its foremost figure, the Greek Herophilus (fl. 300 BC), who dissected human cadavers and thus gave anatomy a considerable factual basis for the first time. Herophilus made many important discoveries and was followed by his younger contemporary Erasistratus, who is sometimes regarded as the founder of physiology. In the 2nd century AD the Greek physician Galen assembled and arranged all the discoveries of the Greek anatomists, including with them his own concepts of physiology and his discoveries in experimental medicine. The many

books Galen wrote became the unquestioned authority for anatomy and medicine in Europe because they were the only ancient Greek anatomical texts that survived the Dark Ages in the form of Arabic (and then Latin) translations.

Owing to church prohibitions against dissection, European medicine in the Middle Ages relied upon Galen's mixture of fact and fancy rather than on direct observation for its anatomical knowledge, though some dissections were authorized for teaching purposes. In the early 16th century, the artist Leonardo da Vinci undertook his own dissections, and his beautiful and accurate anatomical drawings cleared the way for the Flemish physician Andreas Vesalius to "restore" the science of anatomy with his monumental *De humani corporis fabrica libri septem* (1543; "The Seven Books on the Structure of the Human Body"), which was the first comprehensive and illustrated textbook of anatomy. As a professor at the University of Padua, Vesalius encouraged younger scientists to accept traditional anatomy only after verifying it themselves, and this more critical and questioning attitude broke Galen's authority and placed anatomy on a firm foundation of observed fact and demonstration.

From Vesalius' exact descriptions of the skeleton, muscles, blood vessels, nervous system, and digestive tract, his successors in Padua progressed to studies of the digestive glands and the urinary and reproductive systems. Hieronymus Fabricius, Gabriello Fallopius, and Bartolomeo Eustachio were among the most important Italian anatomists, and their detailed studies led to fundamental progress in the related field of physiology. William Harvey's discovery of the circulation of the blood, for instance, was based partly on Fabricius' detailed descriptions of the venous valves.

Microscopic anatomy. The new application of magnifying glasses and compound microscopes to biological studies in the second half of the 17th century was the most important factor in the subsequent development of anatomical research. Primitive early microscopes enabled Marcello Malpighi to discover the system of tiny capillaries connecting the arterial and venous networks. Robert Hooke to first observe the small compartments in plants that he called "cells," and Antonie van Leeuwenhoek to observe muscle fibres and spermatozoa. Thenceforth attention gradually shifted from the identification and understanding of bodily structures visible to the naked eye to those of microscopic size.

The use of the microscope in discovering minute, previously unknown features was pursued on a more systematic basis in the 18th century, but progress tended to be slow until technical improvements in the compound microscope itself, beginning in the 1830s with the gradual development of achromatic lenses, greatly increased that instrument's resolving power. These technical advances enabled Matthias Jakob Schleiden and Theodor Schwann to recognize in 1838-39 that the cell is the fundamental unit of organization in all living things. The need for thinner, more transparent tissue specimens for study under the light microscope stimulated the development of improved methods of dissection, notably machines called microtomes that can slice specimens into extremely thin sections. In order to better distinguish the detail in these sections, synthetic dyes were used to stain tissues with different colours. Thin sections and staining had become standard tools for microscopic anatomists by the late 19th century. The field of cytology, which is the study of cells, and that of histology, which is the study of tissue organization from the cellular level up, both arose in the 19th century with the data and techniques of microscopic anatomy as their basis.

In the 20th century anatomists tended to scrutinize tinier and tinier units of structure as new technologies enabled them to discern details far beyond the limits of resolution of light microscopes. These advances were made possible by the electron microscope, which stimulated an enormous amount of research on subcellular structures beginning in the 1950s and became the prime tool of anatomical research. About the same time, the use of X-ray diffraction for studying the structures of many types of molecules present in living things gave rise to the new subspecialty of molecular anatomy.

Anatomical nomenclature. Scientific names for the parts and structures of the human body are usually in Latin; for example, the name *musculus biceps brachii* denotes the biceps muscle of the upper arm. Some such names were bequeathed to Europe by ancient Greek and Roman writers, and many more were coined by European anatomists from the 16th century on. Expanding medical knowledge meant the discovery of many bodily structures and tissues, but there was no uniformity of nomenclature, and thousands of new names were added as each medical writer followed his own fancy, usually expressing it in a Latin form.

By the end of the 19th century the confusion caused by the enormous number of names had become intolerable. Medical dictionaries sometimes listed as many as 20 synonyms for one name, and more than 50,000 names were in use throughout Europe. In 1887 the German Anatomical Society undertook the task of standardizing the nomenclature, and, with the help of other national anatomical societies, a complete list of anatomical terms and names was approved in 1895 that reduced the 50,000 names to 5,528. This list, the *Basle Nomina Anatomica*, had to be subsequently expanded, and in 1955 the Sixth International Anatomical Congress at Paris approved a major revision of it known as the *Paris Nomina Anatomica*.

Anatosaurus, formerly TRACHODON, genus of bipedal duck-billed dinosaurs, or hadrosaurs, common as fossils in Late Cretaceous rocks (97.5 to 66.4 million years old) of North America; closely related forms have a worldwide distribution. *Anatosaurus*, a very large reptile, grew to a length of between 9 and 12 m (30 to 40 feet) and was heavily built. The

Anatosaurus in Wyoming landscape during the Cretaceous Period, reconstruction painting by Charles R. Knight, 1909

By courtesy of the American Museum of Natural History, New York

hindlimbs and pelvic girdle were very well developed. The skull was long and the beak broad and flat, much like a duck's bill. Several hundred rather blunt teeth were present in the jaws at one time; not all were functional simultaneously, but, as teeth were worn or lost, they were replaced by new ones. It is probable that *Anatosaurus* was aquatic to a certain

degree; its tail was compressed laterally, much like the tails of crocodiles.

Some *Anatosaurus* specimens have been found remarkably well preserved as desiccated mummies; in these, skin and internal structures remain. *Anatosaurus* had webbing between the toes, a further indication of its partially aquatic habit. The outer hide was very leathery and rough. *Anatosaurus* fed mostly on twigs, seeds, fruits, and pine needles; no remains of aquatic plants have been found in its stomach. It seems likely that the aquatic habit of *Anatosaurus* was a means of escaping predators and that they fed while on land rather than in the water.

anatta (Pāli: "non-self," or "substanceless"), Sanskrit ANĀTMAN, in Buddhism, the doctrine that there is in humans no permanent, underlying substance that can be called the soul. Instead, the individual is compounded of five factors of consciousness (Pāli: *khandha*; Sanskrit: *skandha*) that are constantly changing. The concept of anatta, or anatman, is a departure from the Hindu belief in *atman* ("the self"). The absence of a self, *anica* (the impermanence of all being), and *dukkha* ("suffering") are the three characteristics of all existence (*ti-lakkhaṇa*). Recognition of these three doctrines—*anatta*, *anica*, and *dukkha*—constitutes the "right understanding," which is the first stage in the Buddhist system of spiritual discipline leading to enlightenment, known as the Eightfold Path.

anaxite, mineral, an interstratified mixture of kaolinite and free silica. See kaolinite.

Anawrahta, also spelled ANIRUDDHA (fl. 11th century AD), the first king of all of Myanmar, or Burma (reigned 1044–77), who introduced his people to Theravāda Buddhism. His capital at Pagan on the Irrawaddy River became a prominent city of pagodas and temples.

During his reign Anawrahta united the northern homeland of the Burmese people with the Mon kingdoms of the south. He extended his dominion as far north as the kingdom of Nanchao, west to Arakan, south to the Gulf of Martaban (near what is now Yangōn [Rangoon]), and as far east as what is now northern Thailand.

In 1057 Anawrahta captured the Mon city of Thaton, a centre of Indian civilization. Its fall led the other Mon rulers to submit to Anawrahta; for the first time, a Burmese ruler dominated the Irrawaddy River delta. Contact with the Mons enriched Burmese civilization. The Mons gave the Burmese an artistic and literary tradition and a system of writing. The earliest extant Burmese inscription, written in Mon characters, appeared in 1058.

Anawrahta was converted to Theravāda Buddhism by a Mon monk, Shin Arahān. As king, Anawrahta strove to convert his people from the influence of the Ari, a Mahāyāna Tantric Buddhist sect that was at that time predominant in central Myanmar. Primarily through his efforts, Theravāda Buddhism became the dominant religion of Myanmar and the inspiration for its culture and civilization. He maintained diplomatic relations with King Vijayabāhu of Ceylon, who in 1071 requested the assistance of Burmese monks to help revive the Buddhist faith. The Ceylonese king sent Anawrahta a replica of the Buddha's tooth relic, which was placed in the Shwezigon pagoda at Pagan.

Anaxagoras (b. c. 500 BC, Clazomenae, Anatolia [now in Turkey]—d. c. 428, Lampsacus), Greek philosopher of nature remembered for his cosmology and for his discovery of the true cause of eclipses. He was associated with the Athenian statesman Pericles.

About 480 Anaxagoras moved to Athens, then becoming the centre of Greek culture,

and brought from Ionia the new practice of philosophy and the spirit of scientific inquiry. After 30 years' residence in Athens, he was prosecuted on a charge of impiety for asserting that the Sun is an incandescent stone somewhat larger than the region of the Peloponnese. The attack on him was intended as an indirect blow at Pericles, and, although Pericles managed to save him, Anaxagoras was compelled to leave Athens. He spent his last years in retirement at Lampsacus.

Only a few fragments of Anaxagoras' writings have been preserved, and several different interpretations of his work have been made. The basic features, however, are clear. His cosmology grows out of the efforts of earlier Greek thinkers who had tried to explain the physical universe by an assumption of a single fundamental element. Parmenides, however, asserted that such an assumption could not account for movement and change, and, whereas Empedocles sought to resolve this difficulty by positing four basic ingredients, Anaxagoras posited an infinite number. Unlike his predecessors, who had chosen such elements as heat or water as the basic substance, Anaxagoras included those found in living bodies, such as flesh, bone, bark, and leaf. Otherwise, he asked, how could flesh come from what is not flesh? He also accounted for biological changes, in which substances appear under new manifestations: as men eat and drink, flesh, bone, and hair grow. In order to explain the great amount and diversity of change, he said that "there is a portion of every thing, i.e., of every elemental stuff, in every thing," but "each is and was most manifestly those things of which there is most in it."

The most original aspect of Anaxagoras' system was his doctrine of *nous* ("mind," or "reason"). The cosmos was formed by mind in two stages: first, by a revolving and mixing process that still continues; and, second, by the development of living things. In the first, all of "the dark" came together to form the night, "the fluid" came together to form the oceans, and so on with other elements. The same process of attraction of "like to like" occurred in the second stage, when flesh and other elements were brought together by mind in large amounts. This stage took place by means of animal and plant seeds inherent in the original mixture. The growth of living things, according to Anaxagoras, depends on the power of mind within the organisms that enables them to extract nourishment from surrounding substances. For this concept of mind, Anaxagoras was commended by Aristotle. Both Plato and Aristotle, however, objected that his notion of mind did not include a view that mind acts ethically—i.e., acts for the "best interests" of the universe.

Anaximander (b. 610 BC, Miletus [now in Turkey]—d. 546/545 BC), Greek philosopher often called the founder of astronomy, the first thinker to develop a cosmology, or systematic philosophical view of the world.

Anaximander is thought to have been a pupil of Thales of Miletus. Evidence exists that he wrote treatises on geography, astronomy, and cosmology that survived for several centuries, and that he made a map of the known world. As a rationalist he prized symmetry and introduced geometry and mathematical proportions into his efforts to map the heavens. Thus, his theories departed from earlier, more mystical conceptions of the universe and prefigured the achievements of later astronomers.

Only one sentence of Anaximander's writings survives, however, so that reports from later writers form the primary record of his discoveries. That sentence describes the emergence of particular substances such as water or fire in metaphors drawn from human society, in

which injustices are penalized. For example, neither hot nor cold prevails permanently, but each "pays reparations" in order to keep a balance between them.

Anaximander, represented with a sundial, mosaic, 3rd century AD; in the Rhineland Museum, Trier, Ger. By courtesy of the Landesmuseum, Trier, Ger.

Anaximander derived the world from a non-perceptible substance called the *apeiron* ("unlimited"). This state preceded the "separation" into contrasting qualities, such as hot and cold, wet and dry, and thus represents the primitive unity of all phenomena. Anaximander subscribed to the philosophical view that unity could definitely be found behind all multiplicity. A novel element in Anaximander's theory was his rejection of the older notion that the Earth was somehow suspended or supported from elsewhere in the heavens; instead, he asserted that the Earth remained in its unsupported position at the centre of the universe because it had no reason to move in any direction and therefore was at rest.

Anaximenes of Miletus (fl. c. 545 BC), Greek philosopher of nature and one of three thinkers of Miletus traditionally considered to be the first philosophers in the Western world. Of the other two, Thales held that water is the basic building block of all matter, whereas Anaximander chose to call the essential substance "the unlimited."

Anaximenes substituted *aer* ("mist," "vapour," "air") for his predecessors' choices. His writings, which survived into the Hellenistic Age, no longer exist except in passages in the works of later authors. Consequently, interpretations of his beliefs are frequently in conflict. It is clear, however, that he believed in degrees of condensation of moisture that corresponded to the densities of various types of matter. When "most evenly distributed," *aer* is the common, invisible air of the atmosphere. By condensation it becomes visible, first as mist or cloud, then as water, and finally as solid matter such as earth or stones. If further rarefied, it turns to fire. Thus hotness and dryness typify rarity, whereas coldness and wetness are related to denser matter.

Anaximenes' assumption that *aer* is everlasting in motion suggests that he thought it also possessed life. Because it was eternally alive, *aer* took on qualities of the divine and became the cause of other gods as well as of all matter. The same motion accounts for the shift from one physical state of the *aer* to another. There is evidence that he made the common analogy between the divine air that sustains the universe and the human "air," or soul, that animates people. Such a comparison between a macrocosm and a microcosm would also permit him to maintain a unity behind diversity as well as to reinforce the view of his contemporaries that there is an overarching principle regulating all life and behaviour.

A practical man and a talented observer with a vivid imagination, Anaximenes noted the rainbows occasionally seen in moonlight and described the phosphorescent glow given off by an oar blade breaking the water. His thought is typical of the transition from mythology to science; its rationality is evident from his discussion of the rainbow not as a goddess but as the effect of sun rays on compacted air. Yet his thought is not completely liberated from earlier mythological or mystical tendencies, as seen from his belief that the universe is hemispherical. Thus, his permanent contribution lies not in his cosmology but in his suggestion that known natural processes (*i.e.*, condensation and rarefaction) play a part in the making of a world. This suggestion, together with Anaximenes' reduction of apparent qualitative differences in substances to mere differences of quantity, was highly influential in the development of scientific thought.

Anazarbus, in full CAESAREA AD ANAZARBUS, modern AĞAÇLI, formerly ÇEÇENANAVARZA, former city of the ancient province of Cilicia in Anatolia that was important in the Roman and Byzantine periods. It was located in what is now south-central Turkey. Founded by the Romans in 19 BC, it rivaled Tarsus, the Cilician capital, in the 3rd century AD, and later became the seat of the separate Roman province of Cilicia Secunda. Anazarbus was an archbishopric under the Byzantine Empire. After its devastation by earthquakes in the 6th century, it was rebuilt, first as Justinopolis, later as Justinianopolis.

Under Muslim occupation it was renamed 'Ayn Zarbah and retained its strategic importance. It was regained for Byzantium by Nicephorus Phocas about 962 and was subsequently devastated during the Crusades. As Anavarza, it became the capital of Cilician Little Armenia early in the 12th century. The Mamlūks of Egypt finally destroyed the city in 1374.

A Byzantine-Armenian castle—the finest medieval monument in Cilicia—stands on the ruins of the site. A Roman triumphal arch, a theatre, stadium, amphitheatre, aqueducts, and the remnants of several Byzantine churches are also preserved. Pop. (1985) 201.

Anbar, also called MASSICE, or FAIRUZ SAPUR, ancient Mesopotamian town located on the left bank of the Euphrates River, downstream from modern Ar-Ramādī in central Iraq. Originally called Massice and Fairuz Sapor, it was destroyed by the Roman emperor Julian in AD 363. The town was rebuilt and became known from at least the 6th century as Anbar ("Stores"). Jews from the academy of Pumbedita took refuge there from Sāsānian persecution in 588, and it became a Jewish centre. Anbar was the residence of the 'Abbāsīd caliphs from the beginning of that caliphate (750) until the founding of Baghdad (762).

ANC (South African political party): *see* African National Congress.

Ancaeus, in Greek mythology, the son of Zeus or Poseidon and king of the Leleges of Samos. In the Argonautic expedition, after the death of Tiphys, the helmsman of the *Argo*, Ancaeus took his place. According to legend, while planting a vineyard, Ancaeus was told by a seer that he would never drink of its wine. When the grapes were ripe, he squeezed the juice into a cup and, raising it to his lips, mocked the seer, who retorted with the words "There is many a slip between cup and the lip." At that moment it was announced that a wild boar was ravaging the land. Ancaeus set down the cup, leaving the wine untasted, hurried out, and was killed by the boar.

ancestor worship, any of a variety of religious beliefs and practices concerned with the spirits of dead persons regarded as relatives.

Ancestor worship, though not so nearly universal as tendence and fear of spirits of the dead, occurs in widely distributed cultures. It is prevalent in preliterate societies of Africa, Asia, and the Pacific area; existed among the ancient Mediterranean peoples and the peoples of ancient Europe; and is manifest in Asian cultures, particularly in India, China, and Japan.

A brief treatment of ancestor worship follows. For full treatment, *see* MACROPAEDIA: Religious and Spiritual Belief, Systems of.

In cultures that practice ancestor worship the living and the dead are as much related as any other two classes of a given community, for death does not make a person cease to belong to his social unit (family, clan, tribe, village, nation). The dead may be regarded as friendly, as kindred beings with whom kindly relations are possible; or they may be for a time displeased and angry with their people, but such displeasure may be dispelled when proper respect, reverence, and worship are manifest.

Worship directed toward ancestors, who are believed to possess such powers as those just suggested, is of several types. The dead may be worshiped by an entire group—family, clan, tribe, or nation—of which they were members while living. Such communal worship was manifest in the Roman cult of the *manes* or the cult of the *parentum*, which involved the tendence of all the dead of a particular family line. The dead individual as such was not the object of worship, but rather the life force or *genius* of the family or clan.

More prevalent is the worship of individual ancestors, which may be combined in various ways with communal worship, as in the Roman emperor cult, Egyptian worship of ancestral rulers, and Japanese worship of members of the imperial household.

Not all ancestors are equally worthy of worship, for some are regarded as being more powerful than others. Ordinary members of a group, when dead, are tended only by their immediate relatives or perhaps not at all or not for very long, while the spirits of great personages become the focus for more elaborate cultic expression by an entire community. Seniority as well as prominence may have brought about the emergence of a dead person to the rank of a worshipful ancestor. The founder of a family, for example, may be worshiped by that family for an indeterminate number of generations.

Some one ancestor may so combine in his image all the worshipful qualities desired in a worthy ancestor, or show such preeminence in some one quality, that he is no longer treated as a departed spirit but is given the status of a god. An apparent example is Asclepius, who was worshiped in many parts of ancient Greece as a god but was also spoken of as a hero, with a cultic clan (known as the Asclepiadae, a guild of physicians) committed to revere him.

Ancestral spirits may be called upon to assist the community of the living in many ways: to assure the continuation of the line; to avert illness or plague; to assist in the obtaining of good crops (in many cultures ancestors are viewed as living in the ground); and to intercede with gods, since they are associated with gods and often are viewed as living in the sky or in the abode of the deities. There is almost nothing that an ancestral spirit may not be called upon to grant or to avert. Generally, the relation of ancestral spirits to gods is that of inferior to superior, but they are commonly viewed as having a larger share of divine favour than the living.

Anchieta, José de (b. March 19, 1534, Canary Islands, Spain—d. June 9, 1597, Espírito Santo, Brazil), Portuguese Jesuit acclaimed as a poet, dramatist, and scholar. He is considered one of the founders of the national liter-

ature of Brazil and is credited with converting more than a million Indians.

Anchieta came from a prominent Portuguese family and was even thought to be related to the founder of the Jesuit order, St. Ignatius Loyola. He was educated in Portugal and entered the Society of Jesus in 1551. He first arrived in Brazil on July 13, 1553, in what is now the province of Bahia. In 1554 he went to São Paulo, a new Jesuit settlement in the interior, where he played a major role in Jesuit efforts to convert the Indians. For the rest of his life he was influential in converting and helping the Indians, especially in trying to protect them from the institution of slavery, which was developing in the growing plantation economy of the Portuguese colony.

Anchieta's most famous literary work was the Latin mystic poem *De beata virgine dei matre Maria* ("The Blessed Virgin Mary"). He also wrote and staged several religious plays in the Brazilian wilderness, many of which have been lost. In addition, he wrote the first grammar of the Indian language Tupí and many letters describing the Indians' way of life, customs, folklore, and diseases, as well as the flora and fauna of Brazil. His other accomplishments included playing a role in the founding of Brazil's two largest cities, São Paulo and Rio de Janeiro, and the founding of three colleges (at Pernambuco, Bahia, and Rio de Janeiro). He became a provincial of the Jesuit order in Brazil in 1577.

Anchises, in Greek legend, member of the junior branch of the royal family of Troy; he was king of Dardanus on Mount Ida. There the goddess Aphrodite met him and, enamoured of his beauty, bore him Aeneas. For revealing the name of the child's mother, Anchises was killed or struck blind by lightning. In later legend and in Virgil's *Aeneid*, he was conveyed out of Troy on the shoulders of his son Aeneas, whose descendants founded Rome, and he died in Sicily.

anchor, device, usually of metal, attached to a ship or boat by a cable or chain and lowered to the seabed to hold the vessel in a particular place by means of a fluke or pointed projection that digs into the sea bottom.

Ancient anchors consisted of large stones, basketfuls of stones, sacks filled with sand, or logs of wood loaded with lead; these held the vessel merely by their weight and by friction along the bottom. As ships became larger, they required a more effective device to hold them, and wooden hooks that dug into the sea bottom came into use as anchors. Iron replaced wood in their construction, and teeth or flukes were added to help the hooks dig into the bottom. Another major improvement was the addition of a stock, or horizontal arm, that is set at right angles to the arms and

Figure 1: Stock anchor
Encyclopædia Britannica, Inc.

flukes of the lower part of the anchor. The stock ensures that the arms rest vertically on the seabed, and thus one fluke will dig itself in, providing maximum holding power. This type, with its two flukes and its stock at right angles, remained the basic anchor for many centuries. It is known as a stock anchor in the United States and as a fisherman's anchor in the United Kingdom.

Curved arms began to replace straight arms in anchors early in the 19th century. This type of anchor, which is still used for light work and for boats, is shown in Figure 1. The ring (or shackle) is the part of the anchor where the chain or cable is attached. By removing the keep pin, the stock can be removed from the head so that the anchor can be stowed flat on an anchor bed in the ship. The stock must then be folded out again (*i.e.*, stocked) before letting go, to ensure that one of the flukes digs into the ground. The vertical shaft of an anchor is called a shank; it contains a balancing band fitted at the anchor's centre of gravity so that the anchor balances horizontally when lifted. The shank is joined to each arm at the crown. At the end of each arm is a fluke, which consists of a triangular flat face (*i.e.*, a palm) with a pointed bill that digs into the ground.

The stockless anchor (Figure 2), which was patented in England in 1821, came into wide use principally because of its ease of handling and stowing. The crown, arms, and flukes of a stockless anchor are cast in one piece and can pivot slightly from side to side on the shank. The flukes are long and heavy, and have projecting shoulders at their base that catch on the seabed. As more drag is exerted, the shoulders force the flukes downward into the bottom. Stockless anchors have replaced the older stock anchor on most of the large ships of the world.

Figure 2: Stockless anchor
Encyclopædia Britannica, Inc.

Several other types of anchors are in common use. Lightweight, Danforth, and plow anchors have long, sharp flukes that pivot around a stock at the bottom of the shank and bury themselves deeply into the bottom; these anchors are generally used for yachts and other small craft. The mushroom anchor is shaped like an upside-down mushroom and is used widely as a permanent mooring for lightships, dredges, and lighters.

Anchorage, city, southern Alaska, U.S. It is a port at the head of Cook Inlet (a bay of the Pacific). Anchorage was founded in 1914 as the headquarters of the Alaska Railroad running north to Fairbanks. It became a key aviation and defense centre with the construction of Fort Richardson and Elmendorf Air Force Base during World War II. Subsequently, it became a regular stop on air routes from Europe and the United States to East Asia. Anchorage is the largest city and chief commercial centre of Alaska, with an economy based primarily on defense projects and exploitation of natural resources, including oil; tourism is also significant. It is the seat of a campus of the University of Alaska (1954) and of Alaska Pacific University (1957). On March 27, 1964, a severe earthquake caused

a number of deaths and extensive property damage in the city. Inc. 1920. Pop. (1995 est.) city and Anchorage MSA, 251,335.

anchovy, any of numerous schooling saltwater fishes of the family Engraulidae (order Clupeiformes) related to the herring and distinguished by a large mouth, almost always extending behind the eye, and by a pointed

Anchovies (*Engraulis mordax*)
Tom McHugh—Photo Researchers

snout. Most of the more than 100 species live in shallow tropical or warm temperate seas, where they often enter brackish water around river mouths. A few tropical anchovies inhabit freshwater.

Anchovies lay large numbers of elongate, transparent, floating eggs in spring and summer. The eggs hatch in about two days, and the larvae sink to the bottom. Young and adult anchovies feed on plankton, and their growth is rapid. Adult anchovies are 10–25 cm (4–10 inches) long. Temperate-water types such as the northern anchovy (*Engraulis mordax*) and the European anchovy (*E. encrasicolus*) are important food fishes; tropical ones such as the tropical anchovy or anchoveta (*Cetengraulis mysticetus*) are important bait, especially in the tuna fishery. Large numbers of anchovies of the genus *Coilia*, which have long anal fins and tapered bodies, are dried and eaten in China. Many species of anchovies are easily injured and are killed by contact with a net or other solid object.

anchovy pear (*Grias cauliflora*), evergreen tree of the family Lecythidaceae, native to the West Indies. The name is also applied to its edible fruit, for which the tree is cultivated. The plant grows to about 15 m (50 feet) tall and bears spear-shaped, glossy leaves about 90 cm long that are produced in palmlike tufts. The fragrant yellow flowers are about 5 cm across. The fruit, which contains one seed, is pear-shaped, russet brown, and 5–7 cm long.

Anchura, genus of extinct marine gastropods (snails) found as fossils only in marine deposits of Cretaceous age (between 144 and 66.4 million years old). It is thus a useful guide or

Anchura

index fossil because it is easily recognizable. The shell whorls are globular and ornamented with raised crenulations; the spire is sharply pointed; the body whorl, the final and largest whorl, has a prominently extended outer lip.

ancient lights, in English property law, the right of a building or house owner to the light received from and through his windows. Windows used for light by an owner for 20

years or more could not be obstructed by the erection of an edifice or by any other act by an adjacent landowner. This rule of law originated in England in 1663, based on the theory that a landowner acquired an easement to the light by virtue of his use of the windows for that purpose for the statutory length of time. The doctrine did not acquire wide acceptance by courts in the United States.

ancients and moderns, subject of a celebrated literary dispute that raged in France and England in the 17th century. The "ancients" maintained that classical literature of Greece and Rome offered the only models for literary excellence; the "moderns" challenged the supremacy of the classical writers. The rise of modern science tempted some French intellectuals to assume that, if Descartes had surpassed ancient science, it might be possible to surpass other ancient arts. The first attacks on the ancients came from Cartesian circles in defense of some heroic poems by Desmarets de Saint-Sorlin that were based on Christian rather than classical mythology. The dispute broke into a storm with the publication of Nicolas Boileau's *L'Art poétique* (1674), defining the case for the ancients and upholding the classical traditions of poetry. From then on, the quarrel became personal and vehement. Among the chief supporters of the moderns were Charles Perrault and Bernard de Fontenelle. Supporters of the ancients were La Fontaine and La Bruyère.

In England the quarrel continued until well into the first decade of the 18th century. In 1690 Sir William Temple, in his *Essay upon Ancient and Modern Learning* attacking the members of the Royal Society, rejected the doctrine of progress and supported the virtuosity and excellence of ancient learning. William Wotton responded to Temple's charges in his *Reflections upon Ancient and Modern Learning* (1694). He praised the moderns in most but not all branches of learning, conceding the superiority of the ancients in poetry, art, and oratory. The primary points of contention were then quickly clouded and confused, but eventually two main issues emerged: whether literature progressed from antiquity to the present as science did, and whether, if there was progress, it was linear or cyclical. These matters were seriously and vehemently discussed. Jonathan Swift, defending his patron Temple, satirized the conflict in his *Tale of a Tub* (1704) and, more importantly, in *The Battle of the Books* (1704). At a later date Swift was to make an even more devastating attack on the Royal Society in *Gulliver's Travels*, Book III, "The Voyage to Laputa."

Ancillon, Charles (b. July 28, 1659, Metz, France—d. July 5, 1715, Berlin, Prussia [now in Germany]), lawyer, educator, and historian who was the leader of the French Protestant refugees in Germany.

Born of a distinguished family of French Protestants, Ancillon studied law at Marburg, Geneva, and Paris. He pleaded the cause of the Huguenots—the French Protestants—of Metz at the court of Louis XIV, urging that an exception be made for them in the revocation of the Edict of Nantes (1685). Ancillon's efforts were unsuccessful, however, and he moved to Berlin, where he was appointed by Frederick III, the elector of Brandenburg, as judge of the French refugees in that state. Made director in 1687 of the Academy of Nobles, the principal educational establishment of the state, he cooperated with the German philosopher Gottfried Wilhelm Leibniz in the founding of the Academy of Berlin, a society of arts and sciences.

Appointed historiographer to the elector in 1699, Ancillon replaced, in the same year, his uncle, Joseph Ancillon, as judge of all the French refugees. As councillor of embassy at the imperial court, he was involved in the negotiations that resulted in the election of

Frederick the Elector to be king in 1701 as Frederick I. His works include the *Histoire de l'établissement des français réfugiés dans les états de S.A.E. Brandebourg* (1690; "The History of the Establishment of the French Refugees in Brandenburg State") and *L'Ir-révocabilité de l'édit de Nantes* (1688; "The Irrevocability of the Edict of Nantes").

Ancillon, Johann Peter Friedrich, French JEAN-PIERRE-FRÉDÉRIC ANCILLON (b. April 30, 1767, Berlin, Prussia—d. April 19, 1837,

Johann Peter Friedrich Ancillon, detail from a lithograph by Friedrich Jentzen after a drawing by Franz Krüger
By courtesy of the Staatsbibliothek, Berlin

Berlin), Prussian statesman, foreign minister, historian, and political philosopher who worked with the Austrian statesman Metternich to preserve the reactionary European political settlement of 1815.

Educated in Geneva, Ancillon acquired a chair in history at the Berlin Military Academy in 1792. After the publication of *Tableau des révolutions du système politique de l'Europe depuis le XV^e siècle*, 4 vol. (1803–05; "View of European Political Revolutions Since the Fifteenth Century"), he was admitted to the Berlin Academy and became tutor to the future Frederick William IV, in whom he instilled a deep antipathy toward revolution.

During his service with the ministry of foreign affairs, which he headed from 1832 until his death, Ancillon, a Prussian nationalist and romantic, worked closely with Austria and Russia in combating liberalism.

Anckarsvärd, Carl Henrik, Greve (Count) (b. April 22, 1782, Stockholm, Swed.—d. Jan. 25, 1865, Stockholm), a leader of the 1809 coup d'état that deposed the absolutist Swedish king Gustav IV, and a champion of liberal political, economic, and social causes in the first half of the 19th century.

Unlike many other "men of 1809," Anckarsvärd did not retreat from his liberal principles when a democratization of society became a practical possibility. Although a member of the largely conservative noble estate in the Riksdag (estates general), he fought for free trade, open government fiscal policy, a modern parliament, and mass public education. While the experience of the 1848 revolutions caused him to doubt the benefit of universal suffrage, which he had formerly favoured, his efforts were vital to the achievement in 1865 of a modern parliamentary system.

Ancón, city, central Panama, just northeast of Balboa city. It is a residential and medical centre. As Balboa and Panama City have grown, Ancón has become virtually a suburb of the latter. It is noted for the Gorgas Hospital for tropical diseases, named after Colonel William Crawford Gorgas, a U.S. Army surgeon who eradicated yellow fever from the Canal Zone. Ancón is also the site of the Smithsonian Tropical Research Institute for the research and promotion of tropical biology and is on the Transisthmian Railway. Pop. (2000 prelim.) 10,233.

Ancona, capital of *Ancona provincia* and of Marche *regione*, in central Italy, on the Adriatic Sea on the farthest branch of the promontory that descends from the Conero massif. Founded by Syracusan colonists in about 390 bc, it was taken by Rome in the 2nd century bc and became a flourishing port, particularly favoured by the Roman emperor Trajan, who enlarged the harbour. Attacked by Goths, Lombards, and Saracens, Ancona declined but recovered its importance in the Middle Ages; it was one of the five cities of the Maritime Pentapolis under the Byzantine exarchate of Ravenna. The seat of a Carolingian march (frontier borderland), it eventually became a semi-independent republic under papal control; direct papal rule was established in 1532 and, with the exception of a period of French domination (1797–1816), was maintained until Ancona became part of Italy in 1860. The city was bombed by the Austrian fleet (1915) during World War I and suffered severe damage from Allied bombings (1943–44) during World War II.

Notable landmarks, restored since the war, include the marble Arch of Trajan (AD 115); the 11th- to 12th-century Church of Santa Maria della Piazza, with an ornate facade dating from 1210 and remains of 5th- and 7th-century mosaics; and the 12th- to 13th-century Cathedral of San Ciriaco, which is supposed to occupy the site of a Roman temple of Venus and incorporates the remains of a basilica of the 5th–6th century. The city has many fine Gothic buildings and is the site of the National Museum of Marche, with a valuable archaeological collection and art gallery, although some local monuments suffered earthquake damage during the 1970s. Ancona is the seat of an archbishop.

The harbour, originally protected only by the elbow-shaped promontory from which the city takes its name (Greek *angkon*, "elbow"), has

Cathedral of San Ciriaco, Ancona, Italy
SCALA—Art Resource/EB Inc

modern installations built since World War II, including a petroleum refinery. Although Ancona's importance as a port has diminished, it is a busy market centre, with ships plying between Italian and Yugoslav ports on the Adriatic. Ancona is on the main east-coast rail line from Milan and Bologna to Brindisi and Foggia; it is also connected to Rome by a main line. Industries include shipbuilding and the manufacture of machinery, chemicals, medicines, foodstuffs, textiles, furniture, and bricks. Pop. (2000 est.) mun., 98,329.

Ancre, Concino Concini, marquis d': see Concini, Concino.

Ancud, town and commune in Los Lagos *región*, Chiloé *provincia*, southern Chile. It lies on the northern coast of Chiloé Island, across the Straits of Chacao from the mainland. Founded in 1769 as San Carlos de Ancud, it was one of the last strongholds of royalist forces during Chile's struggle for independence from Spain in the first quarter of the 19th century. It was the provincial capital of Chiloé *provincia* from 1937 to 1974. Ancud is a port, resort, and commercial centre for

its hinterland, which yields potatoes, wheat, livestock, and timber. Timber is its principal export. The town is linked by road and ferry to Puerto Montt and by road to Castro, the provincial capital and oldest settlement on Chiloé Island. Pop. (1980) town 16,614; (1987 est.) mun., 31,919.

Ancus Marcius (fl. 7th century bc), traditionally the fourth king of Rome, from 642 to 617 bc. The details of his reign, provided by Roman historians such as Livy (64 or 59 bc–ad 17), must be regarded as largely legendary—e.g., the settlement of the Aventine Hill outside Rome, the first extension of Rome beyond the Tiber River to the Janiculum Hill, and the founding of the port of Ostia at the mouth of the Tiber.

ancylostomiasis: see hookworm disease.

Ancylus stage, early span of postglacial time in northern Europe marked by an impounding and freshening of the Baltic Sea Basin. The Ancylus stage, characterized by the common fossil snail genus *Ancylus*, lasted about 2,000 years—from about 8,500 to 6,500 years ago. The Ancylus Lake was formed as a result of crustal uplift along the southwestern margin of the Baltic Basin, which was produced by the withdrawal of the thick continental ice sheet from the land. It probably attained its greatest size (larger than that of the present Baltic Sea, more than 160,000 square miles [414,000 square km]) about 6500 bc and then once again became a saline, ocean-connected body before 4500 bc, when the rising level of the sea, resulting from increased melting of the ice sheet, finally overflowed the land and once again made the Baltic an arm of the sea. At its maximum extent, the Ancylus Lake covered a large area of present Sweden and Finland. A rich fossil record, including pollen information, has provided a full history of the Ancylus Lake.

And Fjord, Norwegian ANDFJORDEN, fjord, in the Norwegian Sea, indenting northwestern Norway, located between the islands of And (west) and Senja (east). The fjord, which is divided between Nordland and Troms *fylker* (counties), penetrates into the offshore island of Hinn in the south, where it is called Gulles Fjord. Its total length is about 55 miles (90 km) from its broad opening into the Norwegian Sea at the Andenes lighthouse on And Island to its head in the interior of Hinn Island, the largest Norwegian island except Svalbard (Spitsbergen).

Consult the INDEX first

Andalusia, Spanish ANDALUCIA, *comunidad autónoma* ("autonomous community") and historic region of Spain, encompassing the southernmost Spanish *provincias* of Huelva, Cádiz, Sevilla, Málaga, Córdoba, Jaén, Granada, and Almería. The *comunidad autónoma* was established by the statute of autonomy in 1981.

Andalusia corresponds roughly to the ancient Roman province of Baetica. The Arabic name Al-Andalus was originally applied by the Muslims (Moors), who occupied Spain in the 8th century, to the whole Iberian Peninsula. It probably means the country of the Vandals—a Germanic people who had invaded Spain in the 5th century. In the 11th century, when the Christians began to reconquer the peninsula, Al-Andalus, or Andalusia, came to mean only the area still under Muslim control and thus became permanently attached to the region defined above. After the breakup of the unified Spanish Muslim state in the early 11th century, Andalusia was divided into a number of small kingdoms, which had a strong

cultural and artistic influence on the northern Africans, who in turn reinvigorated Spanish Islām. Northern African influence was finally excluded in the 14th century, and by the end of the 15th century all of Andalusia had been incorporated into the Christian kingdom of Castile. The present-day *provincias* were created in 1833. The government of the *comunidad autónoma* established in 1981 consists of an executive council (headed by a president) and a unicameral parliament.

Andalusia faces both the Atlantic Ocean and the Mediterranean Sea to the southeast, with the *provincias* of Huelva and Cádiz bordering the Gulf of Cádiz on the west and the *provincias* of Málaga, Granada, and Almería opening on the Mediterranean. These two distinctive marine zones display sharp variations in terrain and climate, working against a strong sense of regionalism in the populace. The topography of Andalusia is divided by mountain ranges into several distinct zones, each running southwest to northeast. The Morena Mountains form the northernmost range, comprising parts of the *provincias* of Huelva, which borders Portugal, and Sevilla and Córdoba, which adjoin the Castilian *provincias* of Badajoz and Ciudad Real. The Morena Mountains present a relief of desolate ridges punctuated by narrow valleys that sheltered bandits well into the 18th century. The Morena Mountains are terminated to the south by the Guadalquivir, or Baetic, basin, a triangular plain drained southwestward by the Guadalquivir River and partitioned by human occupation into large estates, or *latifundios*. The Penibético, or Baetic, Mountains rise abruptly to the south, forming an alpine range with the highest elevations in the Iberian Peninsula south of the Pyrenees. The Baetic Mountains extend southward from the *provincia* of Jaén into Granada and Almería, which border the Castilian *provincias* of Ciudad Real and Albacete, and give way to the Andalusian steppes in the southeast corner of the peninsula. The steppes descend from the border of the *provincia* of Murcia (east) and cover much of Granada and Almería *provincias*. The Baetic Mountains effectively block precipitation from reaching the steppes, creating a region of badlands with scorched tablelands and sharp gorges. Mediterranean Andalusia stretches southwestward from the city of Almería to the western limits of Málaga *provincia*. The region is one of Spain's most popular tourist rivieras (the Costa del Sol being the westernmost part of this coastline), with mountains commonly extending down to the sea. Geologic uplift and erosion of the mountains have enlarged the coastal deltas since antiquity.

A Mediterranean climate prevails in most of Andalusia, with mild and rainy winters; colder climate marks the Baetic Mountains, where heavy snows and low temperatures leave the upper reaches snowbound between November and May. Annual precipitation ranges from 40 inches (1,000 mm) in the Nevada Mountains to as little as 4 inches (100 mm) in the desert Andalusian steppes.

The population of western Andalusia has traditionally been concentrated in large rural towns from which agricultural labourers commute daily to work on the surrounding estates, or *cortijos*, but in modern times the population has concentrated more in the provincial capitals. From the Baetic Mountains eastward, small villages predominate wherever water is available. Emigration to industrialized regions of Spain and western Europe has led to a leveling off of population growth despite the region's high birth rate. However, emigration declined in the late 20th century as demand for imported labour diminished in the countries of the European Community.

Andalusia is underdeveloped, accounting for a disproportionately small percentage of Spain's gross national product and for a disproportionately high percentage of agricultural output. *Latifundios* have dominated Andalusian agriculture since the reconquest (completed 1492), producing the traditional Mediterranean crops of wheat, grapes, and olives by dry farming. The large farms have increased the mechanization of agriculture, but the region continues to lag behind the national average in the use of tractors, irrigation, and fertilizers.

The region's industrial sector is poorly developed and is dominated by the processing of agricultural products and mining; manufacturing is of relatively little importance. Wine and brandy are produced in Jerez (where sherry originated), Niebla, Montilla, and Málaga, while the *provincias* of Sevilla, Córdoba, and Jaén process large quantities of olive oil. Andalusia's mining, though still substantial, is in decline, having reached its peak toward the late 19th century, when Spain led Europe in the exploitation of minerals. Virtually all of Andalusia's production of copper and lead was then exported to Great Britain and Germany, although the region benefited relatively little from the boom because of extensive foreign ownership of the mines. Andalusia has remained an important mining region, still producing large quantities of coal, iron, copper, and lead.

Andalusia suffers from an energy deficit despite the extensive deposits of coal in the Morena Mountains and the exploitation of hydroelectric resources of the upper reaches of the Guadalquivir River and the lower regions of the Baetic Mountains; water from the latter is used for irrigation during seasonal droughts. Andalusia's service sector has benefited from the spread of tourism, with large numbers of hotels being built along the Mediterranean coast as well as in the architecturally rich cities of Granada, Córdoba, and Seville. The growth of tourism has not been matched by growth in other economic sectors.

Andalusian culture is heterogeneous and reflects crosscurrents from Europe, Africa, the Atlantic, and the Mediterranean. The observance of Roman Catholicism is heavily ceremonial, with towns hosting elaborate processions during Holy Week and town guilds staging ostentatious pilgrimages, or *romerías*, at various times during the year. Pop. (1991 prelim.) 6,859,958.

Andalusia, city, seat (1841) of Covington county, southern Alabama, U.S., near the Conecuh River. It originated in the 1830s as New Site (relocated on higher ground because of floods) and was crossed by the Three-Notched Trail, used by Andrew Jackson during his Creek Indian campaign (1813–14). Renamed Andalusia in 1846, it developed after the arrival in 1899 of the Central of Georgia and the Louisville and Nashville railroads. An agricultural and timber-based economy prevails, supplemented by light manufacturing. Lurleen B. Wallace State Junior College was opened in 1969. Conecuh National Forest is nearby. Inc. 1901. Pop. (1990) 9,269.

andalusite (Al_2SiO_5), aluminum silicate mineral that occurs in relatively small amounts in various metamorphic rocks, particularly in altered sediments. It is found in commercial quantities at White Mountain, Calif., and Orono, Nev., in the United States; Kazakhstan; and the Transvaal, South Africa. Such deposits are mined as a raw material for refractories and porcelain used in spark plugs and other products. For detailed physical properties, see silicate mineral (table 2).

Andalusite of gem quality occurs as greenish or reddish pebbles at Minas Gerais, Braz., and in Sri Lanka. The variety chialiolite (also called cross-stone, or macle), characteristic of clay slates near a granite contact, forms elongated

Andalusite from Tirol, Austria

gated prismatic crystals enclosing symmetrically arranged wedges of carbonaceous material. In cross section, it shows a black cross on a grayish ground; polished cross sections of the mineral are sometimes worn as charms.

Andaman and Nicobar Islands, union territory of India, consisting of two island groups in the Bay of Bengal. The Andamans are separated from the Nicobars to the south by the Ten Degree Channel, which is 90 miles (145 km) wide. The capital of the territory is Port Blair.

A brief treatment of the Andaman and Nicobar Islands follows. For full treatment, see *MACROPAEDIA: India*.

The Andaman group includes more than 300 islands and islets, of which 26 are inhabited. The three chief islands in the principal group—North, Middle, and South Andaman—are so closely positioned that they have been known collectively as Great Andaman. The Nicobars are a group of 12 inhabited and 7 uninhabited islands; they include Great Nicobar (largest and southernmost), Kamorta and Nancowry (central group), and Car Nicobar (northern group). The principal harbours are Port Blair, Diglipur, Rangat, Neil, and Mayabandar in the Andamans and Car Nicobar and Kamorta in the Nicobars.

Because of their position on the trade routes between India and Myanmar (Burma), their existence has been known from earliest times. After the mid-18th century the islands were associated with the British, who established penal colonies there. They were occupied by the Japanese (1942–45) and passed to India on the establishment of Indian independence (1947). In the 1950s the Andamans were colonized with displaced persons from East Pakistan (now Bangladesh), evacuees from Myanmar, and Indian emigrants from British Guiana (now Guyana).

Exports from the territory include timber (especially Andaman redwood, gurjan for plywood, and softwoods), coconuts, and copra. Area 3,185 square miles (8,249 square km). Pop. (1991 prelim.) 279,111.

Andaman Islands, island group, Andaman and Nicobar Islands union territory, India, in the southeastern part of the Bay of Bengal. The Andamans constitute one of the two major groups of islands in the union territory. They include more than 300 islands (26 inhabited), with a land area of 2,474 square miles (6,408 square km). The three major islands are North Andaman, Middle Andaman, and South Andaman (closely positioned and collectively known as Great Andaman). Also prominent is Little Andaman, to the south. Of the original inhabitants, only the Jarawa and Onge, on the islands of South Andaman, Rutland, and Little Andaman, retain a traditional hunting-and-gathering way of life.

The Andamans, situated on the ancient trade

route between India and Myanmar (Burma), were visited by Lieutenant Archibald Blair of the Bombay Marine (the East India Company's navy) in 1789. The first European settlement on the islands was at Port Blair, situated along the eastern coast of South Andaman. It is now the union territory capital.

The islands are a succession of dome-shaped hill ranges running parallel to each other from north to south. The highest peak is Saddle, rising 2,418 feet (737 m) on North Andaman. Flat land is scarce and confined to a few valleys, such as the Bitampur and Diglipur. The islands are formed of highly dissected sandstone, limestone, and shale. Their surface is covered with dense forest, and large mangrove swamps occur in the northern part of North Andaman. Perennial rivers are few.

Agriculture is the principal occupation; crops include cereals, pulses (legumes), coconuts, betel nuts, fruits, cassava, chilies, and turmeric. There is little industry. An interisland steamer service connects Port Blair with North, Middle, South, and Little Andaman. The Indian revolutionary Vinayak Damodar (Vir) Savarkar was imprisoned (1911–37) in the Cellular Jail (declared a national monument in 1979) in Port Blair. In 2004 the islands were struck by a large tsunami triggered by an earthquake in the Indian Ocean near Indonesia. Coastal areas of the Andamans suffered extensive damage, and scores of people were killed. Pop. (2001) 314,239.

Andaman Sea, marginal sea of the northeastern Indian Ocean. It is bounded to the north by the Irrawaddy River delta of Myanmar (Burma); to the east by peninsular Myanmar, Thailand, and Malaysia; to the south by the Indonesian island of Sumatra and by the Strait of Malacca; and to the west by the Andaman and Nicobar Islands (a union territory of India). Through such ports as Bassein, Moulmein, and Yangôn (Rangoon), it forms the most important sea link between Myanmar and other countries and part of a major shipping route between India and China, via the Strait of Malacca. The sea, which has an area of 308,000 square miles (798,000 square km), takes its name from the Andaman Islands.

The Andaman Sea is 750 miles (1,200 km) long from north to south and 400 miles (645 km) wide. Less than 5 percent of the sea is deeper than 10,000 feet (3,000 m), but, in a system of submarine valleys east of the Andaman-Nicobar Ridge, depths exceed 14,500 feet (4,400 m). The sea's northern and eastern third is less than 600 feet (180 m) deep, in part because vast quantities of silt have been deposited at the Irrawaddy delta. The western and central half of the sea is 3,000 to 10,000 feet (900 to 3,000 m) deep.

Southeast Asia's monsoonal regime governs the sea's climate and water chemistry. In winter the regional humidity is low, the sea receives little rainfall or runoff, and its surface salinities are high. Huge volumes of runoff water from Myanmar flow into the Andaman Sea during the summer monsoon, producing low surface salinity in its northern third.

Neither the Andaman's surface waters nor its bottom are rich in marine life, though mollusks and some 250 species of edible fish flourish along the coastal waters of the Malay Peninsula. The sea's mineral resources are similarly limited but include tin deposits off the coasts of Malaysia and Thailand.

Trading vessels have plied the Andaman Sea since ancient times. It was part of the early coastal trade route between India and China and, from the 8th century, formed a link in a thriving trade between India and Sri Lanka (Ceylon) to the west and the Myanmar ports of Thaton, Martaban, and Tavoy to the east. The two largest modern ports on the sea are George Town (Malaysia) to the southeast and Yangôn (Myanmar) to the north. In 2004 a severe earthquake (magnitude 9.0) off the west

coast of Sumatra triggered a large tsunami that inundated coastal areas throughout the Andaman Sea region. The initial quake was followed by a series of aftershocks along the arc of the Andaman and Nicobar Islands.

Andamanese, aboriginal inhabitants of the Andaman and Nicobar Islands in the Bay of Bengal. They are of Negrito ancestry, the group including the Semang of Malaysia and the Pygmies of the Philippines. Most have been absorbed into modern Indian life, but traditional culture survives among such tribes as the Jarawa and Ongé of the lesser islands.

Until the mid-19th century, the remoteness of the Andamanese and their practice of killing foreigners preserved them from any considerable physical or cultural modification. A small number still live mainly by hunting and collecting. The only indigenous weapon is the bow, used both for fishing and for hunting wild pigs; they have no traps or fishhooks. Turtle, dugong, and fish are caught with nets and harpoons; the latter are used from single-outrigger canoes. Pottery is made, and iron, obtained from wrecks, has been used for arrowheads, knives, and adzes from at least the 18th century. It is shaped by breaking and grinding, a technique derived from the working of shell. The Andamanese were unique in knowing no method of making fire.

Andamanese language, language spoken by the indigenous people of the Andaman Islands. The number of speakers of the language has been steadily decreasing. Andamanese dialects are usually classified into great (northern, and central) and southern groups. The dialect of Little Andaman island is the southernmost of the Andamanese dialects and diverges greatly from the others. One of the chief characteristics of Andamanese grammar is the use of affixes (especially prefixes) to specify the functions of the words of a sentence. The language has no number system; the two number words in the language mean "one" and "more than one." Andamanese is not known to be related to any other language.

Andania mysteries, ancient Greek mystery cult, held in honour of the earth goddess Demeter and her daughter Kore (Persephone) at the town of Andania in Messenia. A long inscription of 92 BC gives elaborate directions for the conduct of the rites, although it relates no details of the initiation ceremonies. The ritual was performed by certain "holy ones" of both sexes, who were chosen from the various tribes, presumably the same number from each tribe.

Initiation seems to have been open to men, women, and children, bonded and free, and some details have survived as to the costumes to be worn by each class of initiates: all costumes were to be severely plain and of inexpensive material. An exception was made for those who were to be "costumed into the likeness of deities," from which many scholars have assumed that a pageant or drama was performed. There was a procession, precedence in which was strictly regulated, and the main ceremonial was preceded by sacrifices to a number of deities.

Andean bear: *see* spectacled bear.

Andean civilization, the complex of American Indian cultures that evolved in the Andean region of western South America prior to the Spanish exploration and conquest in the 16th century. In its level of cultural development, this civilization, along with the comparable Meso-American civilization to the north, constitutes a New World counterpart to those of ancient Egypt, China, and Mesopotamia.

A brief treatment of Andean civilization follows. For full treatment, *see* MACROPAEDIA: Pre-Columbian Civilizations.

Andean civilization spread along the Pacific coast and inland into the high Andes in what

arc now Peru, Ecuador, western Bolivia, and extreme northern Chile. Dates as early as 15,000 BC have been postulated for the arrival of humans in the Andes region. The oldest primary food crops used by these people were the lima bean and the potato, though corn (maize) appeared soon after the beginning of settled village life. There is ample evidence of lowland occupation by 3500 BC. About that time, in what is known as the Preceramic Period, beans, squash, chili peppers, and cotton were domesticated. Fishing provided sustenance and by 2500 BC supported permanent settlements along the arid Pacific coast. The appearance of elaborate twined textiles during this period anticipates the important role that medium would have as a peculiarly Andean art form.

The introduction of pottery, perhaps before 2000 BC, marks the beginning of the next epoch, called variously the Initial Period and the Lower Formative. Another important technological advance at this time was the development of the heddle loom, which was used to make cotton fabrics. Village life and temple-mound construction spread from the coast of central Peru during the Initial Period to all regions except the far south. The growing of corn spread north and south from the central coastal region, and peanuts (groundnuts) and cassava were also adopted as food crops. Distinctive regional styles began to appear in pottery and architecture.

Sometime about the year 1000 BC there occurred a pervasive artistic unification known as the Chavín (*q.v.*) style, named for a highland temple complex in central Peru from which the style may have radiated. The Chavín style signifies the consolidation of the Peruvian coast and highlands into a single polity, in a period termed the Early Horizon. The Chavín stone temples were decorated with carvings of feline, human, and snake figures in highly complex and fantastic forms. The related Paracas (*q.v.*) style of the southern Peruvian coast is evident in pottery as well as in sumptuous embroidered textiles.

Upon the decline of Chavín influence about 200 BC, artistic and technological flowerings occurred in a number of regional centres. Along the southern Peruvian coast, this Intermediate Period is characterized by the evolution of the Paracas pottery style into that of the Nazca (*q.v.*), or Nasca. Moche (*q.v.*), or Mochica, artifacts and ruins from the northern Peruvian coast indicate the existence of an aggressive warrior state using irrigated agriculture in arable valleys. The Recuay (*q.v.*) style predominates in Intermediate pottery of the northern Peruvian highlands. Large urban and ceremonial centres, notably Pucará and Tiahuanaco (*q.v.*), emerged at this time near Lake Titicaca in the southern highlands.

By AD 600, multi-valley political rule had expanded sufficiently from two centres—in the southern highlands and at Huari (*q.v.*) in central highland Peru—to effect another cultural unification, known as the Middle Horizon. The remains of large groups of food-storage buildings in the Huari strongholds suggest military activity like that of the late Inca. Several great cities originated at this time, but, when the Huari empire reached its maximum extent about AD 800, it collapsed at the centre, and urban life throughout the south declined.

The Late Intermediate Period (AD 1000–c. 1400) followed, toward the end of which time two well-organized states—Chimú (*q.v.*) in the north and Chíncha in the south—rose to prominence. In the early 15th century, however, the Inca (*q.v.*), from their capital at Cuzco in the southern Peruvian highlands, undertook the series of conquests that would rapidly forge the entire Andean region into a single empire. Immense storehouses for food and textiles indicate a highly productive agri-

culture and industry, as well as the vastness of the army that these stockpiles supported. Ruins such as those at Machu Picchu (*q.v.*) reveal much about Inca urban life. Ironically, the extensive highway network constructed to facilitate trade and administration gave the invading Spaniards easy passage into the empire's heart in the 1530s.

Andean Community, Spanish COMUNIDAD ANDINA (CAN), formerly (1969–97) ANDEAN GROUP, South American organization founded to encourage industrial, agricultural, social, and trade cooperation. The organization was formed in 1969 by the Cartagena Agreement, and its members include Bolivia, Colombia, Ecuador, Peru, and Venezuela. CAN's headquarters are in Lima, Peru.

In the 1990s CAN attempted, with mixed success, to achieve a level of economic integration among its members similar to that of the European Union. In 1993 the group began negotiations to harmonize its customs policy and reached an agreement the following year on a common external tariff that covered 90 percent of imports. CAN later endorsed an accord between Colombia, Venezuela, and Mexico to phase out tariffs. In 2004 a free-trade pact between CAN and Mercosur (the Southern Common Market) went into effect.

Andean Geosyncline, a linear trough in the Earth's crust in which rocks of the Mesozoic Era (245 to 66.4 million years ago) and Cenozoic Era (66.4 years ago to the present) were deposited in South America. An intense orogenic (mountain-building) event affected the older sediments in the geosyncline in the Late Cretaceous Epoch (97.5 to 66.4 million years ago) and, combined with later deformational episodes, produced a pattern of scattered marine deposition in basins along the western margin of the geosyncline. The total area of deposition was great enough for some geosynclinal segments to be separately named—*e.g.*, the Venezuelan-Peruvian Geosyncline. The rising highland belts provided much coarse sediment, and thicknesses as great as 6,080 m (20,000 feet) are known from early Cenozoic sequences. During middle Cenozoic time, another orogenic phase occurred, accompanied by widespread volcanism. A complex history of intermittent uplift, block faulting, and erosion in late Cenozoic time led to a series of extensive uplifted erosion surfaces in Peru, Bolivia, and elsewhere. Uplift continued through the late Pleistocene Epoch (1,600,000 to 10,000 years ago), giving rise to the present configuration of the Andes. Elevations of 4,600 m (15,200 feet) are widespread, and many peaks attain 6,000 m (19,800 feet) or more.

Anderlecht, municipality, Brabant province, central Belgium. It lies along the Charleroi-Brussels Canal, just southwest of Brussels, and is one of the 19 communes making up the Greater Brussels area.

A natural clearing in the primitive forest where foundations of a Roman villa and Frankish cemeteries have been found, Anderlecht is believed to be the original site of what is now Brussels. It is now chiefly a residential and manufacturing suburb; its industries include textiles, leather, chemicals, lumber, paper, and glassware. Medieval remains include the Church of Saints Peter and Guidon, containing an 11th-century crypt of Saint Guidon (the patron saint of farm animals), and a *béguinage* (retreat for secular nuns) dating from 1252. A museum commemorating a visit in 1521 by Desiderius Erasmus, a Dutch scholar, is located in the municipality, as is a university hospital attached to the Free University of Brussels. Pop. (2002 est.) mun., 90,134.

Anders, William A(lison) (b. Oct. 17, 1933, Hong Kong), U.S. astronaut who participated

in the Apollo 8 flight (Dec. 21–27, 1968), in which the first manned voyage around the Moon was made. The astronauts, including Anders, Frank Borman, and James Lovell, remained in an orbit about 70 miles (112 km) above the surface of the Moon for about 20 hours, transmitting television pictures back to Earth and verifying that lunar landmarks could be used for navigation to lunar landing sites.

Anders resigned from the National Aeronautics and Space Administration and the Air Force in 1969 to become executive secretary of the National Aeronautics and Space Council. He served as a member of the Atomic Energy Commission (1973–74) and of the Nuclear Regulatory Commission (1974–76); and as U.S. ambassador to Norway (1976–77). He later worked for several corporations.

Anders, Wladyslaw (b. Aug. 11, 1892, Blonie, Pol., Russian Empire—d. May 12, 1970, London, Eng.), army officer who commanded the Polish forces in the Middle East and Italy during World War II and became a leading figure among the anticommunist Poles who refused to return to their homeland after the war.

After service in the Russian army during World War I, Anders entered the armed forces of the newly reconstituted Polish state and fought the Red Army in the Russo-Polish War of 1919–20. Campaigning against both Germany and the Soviet Union at the outbreak of World War II (September 1939), he was captured by the Soviets and imprisoned until the Polish-Soviet agreement of August 1941. Allowed to form a Polish fighting force on Russian soil from former prisoners of war and deportees, Anders soon had 80,000 men, but he realized that he had no chance of liberating Poland from the East with an army now under Soviet control. As a result of both Polish and British pressure, Joseph Stalin allowed Anders to march into Iran and Iraq (1942). The Poles subsequently distinguished themselves in the Italian campaign, capturing Monte Cassino. A staunch anticommunist, Anders remained in Great Britain after World War II; the new communist Polish government deprived him of his citizenship in 1946. Thereafter he became a prominent leader of Polish exiles in the West.

Andersen, Hans Christian (b. April 2, 1805, Odense, near Copenhagen, Den.—d. Aug. 4, 1875, Copenhagen), unique master of the fairy tale whose stories are famous throughout the world; he is also the author of plays, novels, poems, travel books, and several autobiographies. While many of these works are almost unknown outside Denmark, his fairy tales are among the most frequently translated works in all literary history.

Andersen was born in a slum and had a difficult battle breaking through the rigid class structure of his time. The first significant help came from Jonas Collin, one of the directors of the Royal Theatre in Copenhagen, to which Andersen had gone as a youth in vain hopes of winning fame as an actor. Collin raised money

Hans Christian Andersen
The Bettmann Archive

to send him to school. Although school was an unhappy experience for Andersen because of an unpleasant headmaster, it allowed him to be admitted to the University of Copenhagen in 1828.

The next year he produced what is considered his first important literary work, *Fodrejse fra Holmens Kanal til Ostpynten af Amager i aarene 1828 og 1829* (1829; "A Walk from Holmen's Canal to the East Point of the Island of Amager in the Years 1828 and 1829"), a fantastic tale in the style of the German Romantic writer E.T.A. Hoffmann. This work was an immediate success. He then turned to playwriting. After two unsuccessful attempts, he achieved recognition for *Mulatten* (1840; "The Mulatto"), a play portraying the evils of slavery, but the theatre was not to become his field, and for a long time Andersen was regarded primarily as a novelist. Most of his novels are autobiographical; among the best-known are *Improvisatoren* (1835; *The Improviser*), *O.T.* (1836), and *Kun en spillemand* (1837; *Only a Fiddler*).

Andersen's first book of tales, *Eventyr, fortalte for børn* (1835; "Tales, Told for Children"), included such stories as "The Tinderbox," "Little Claus and Big Claus," "The Princess and the Pea," and "Little Ida's Flowers." Two further installments of stories made up the first volume of *Eventyr* (1837); a second volume was completed in 1842, and to these was added *Billedbog uden Billeder* (1840; *A Picture-book Without Pictures*). New collections appeared in 1843, 1847, and 1852. The genre was expanded in *Nye eventyr og historier* (1858–72; "New Fairy Tales and Stories").

These collections broke new ground in both style and content. A real innovator in his method of telling tales, Andersen used the idioms and constructions of the spoken language, thus breaking with literary tradition. While some of his tales reveal an optimistic belief in the ultimate triumph of goodness and beauty (*e.g.*, "The Snow Queen"), others are deeply pessimistic and end unhappily. Indeed, one reason for Andersen's great appeal to both children and adults is that he was not afraid of introducing feelings and ideas that were beyond a child's immediate comprehension, yet he remained in touch with the child's perspective. He combined his natural storytelling abilities and great imaginative power with universal elements of folk legend to produce a body of fairy tales that relates to many cultures.

It may also be noted that part of what makes some of the tales so compelling is Andersen's identification with the unfortunate and the outcast. A strong autobiographical element runs through his sadder tales; throughout his life he perceived himself as an outsider, and, never satisfied that he was completely accepted, he suffered deeply in his closest personal relationships.

From 1840 to 1857 Andersen traveled throughout Europe, Asia Minor, and Africa, and his impressions are recorded in a number of travel books (notably *En digters bazar* [1842; *A Poet's Bazaar*], *I Sverrig* [1851; *Pictures of Sweden*], and *I Spanien* [1863; *In Spain*]). Because Andersen rarely destroyed anything he wrote, his diaries and thousands of his letters are extant.

BIBLIOGRAPHY. Elias Bredsdorff, *Hans Christian Andersen* (1975); Bo Grønbech, *Hans Christian Andersen* (1980).

Andersen, Tryggve (b. Sept. 27, 1866, Ringsaker, Nor.—d. April 10, 1920, Gran), novelist and short-story writer of the Neoromantic movement in Norway who depicted the conflict between the bureaucratic and peasant cultures.

Born on a farm and educated at the University of Kristiania, Andersen was an office worker. The young Andersen was fascinated

with German Romanticism, especially as seen in the fantastic tales of E.T.A. Hoffmann, but Gotthold E. Lessing developed Andersen's interest in literature and style. In his main work, *I cancelliraadens dage* (1897; *In the Days of the Counsellor*), short stories tied together by their central figure, Andersen portrayed the world of rural civil servants in Norway. His other novel, *Mot kvæld* (1900; "Toward Evening"), dealt with middle-class narrow-mindedness. He also published four volumes of short stories. His diary of a sea voyage after the death of his wife and a son in 1902, *Dagbog fra en sjøreise* ("Journal of a Sea Voyage"), appeared in 1923.

Andersen's disease, also called GLYCOGENOSIS TYPE IV, extremely rare hereditary metabolic disorder produced by absence of the enzyme amylo-1:4,1:6-transglucosidase, which is an essential mediator of the synthesis of glycogen. An abnormal form of glycogen, amylopectin, is produced and accumulates in body tissues, particularly in the liver and heart. Affected children appear normal at birth but fail to thrive and later lose muscle tone, becoming lethargic. The liver and spleen become enlarged, and progressive liver failure occurs prior to death, usually before age three, caused by heart failure or bleeding from the esophagus. Liver transplants have proved successful in treating the disorder. Donated livers are often able to produce enough of the enzymes necessary to stop the accumulations of abnormal glycogen. Andersen's disease is transmitted as an autosomal-recessive trait, as are most similar enzyme defects.

Anderson, city, seat (1828) of Madison county, east-central Indiana, U.S. It lies along the White River, 38 miles (61 km) northeast of Indianapolis. Founded in 1823 on the site of a Delaware Indian village, it was named Andersontown for a subchief known as William Anderson. In 1886 the town's industrial growth was assured with the discovery of natural gas in the locality. The city's manufactures now include automobile parts and electric vehicles. Anderson University was established in 1917 as the Anderson Bible Training School by the Church of God, whose world headquarters are also located in the city. Mounds State Park, just east of Anderson, contains the largest known single Native American-built earthwork in Indiana, as well as several other prehistoric mounds. Inc. 1838, again in 1865. Pop. (2000) 60,722.

Anderson, city, seat (1826) of Anderson county, northwestern South Carolina, U.S., in the foothills of the Blue Ridge Mountains. It was founded in 1826 on what had been Cherokee Indian land. Named for a local Revolutionary War hero, General Robert Anderson, it has been called the Electric City because of early (1898) long-distance power transmission from the Seneca River.

Anderson is a manufacturing centre with a long-established textile industry; newer industries produce fibreglass products, auto parts, electrical appliances, rubber products, and machinery and parts. Anderson College (1911; Baptist) traces its origins to the Johnson Female Seminary (1848). Clemson University (1889) is 18 miles (29 km) northwest of Anderson. Hartwell Dam (1963), impounding Hartwell Lake on the Savannah River, provides hydroelectricity and recreation facilities. Inc. 1882. Pop. (2000) city, 25,514; Greenville-Spartanburg-Anderson MSA, 962,441.

Anderson, Carl David (b. Sept. 3, 1905, New York, N.Y., U.S.—d. Jan. 11, 1991, San Marino, Calif.), American physicist who, with Victor Francis Hess of Austria, won the Nobel Prize for Physics in 1936 for his discovery of the positron, or positive electron, the first known particle of antimatter.

Anderson received his Ph.D. in 1930 from the California Institute of Technology, Pasade-

Carl David Anderson
Harvey of Pasadena

na, where he spent his entire career, becoming professor emeritus in 1976. Having studied X-ray photoelectrons (electrons ejected from atoms by interaction with high-energy photons) since 1927, he began research in 1930 on gamma rays and cosmic rays, utilizing the magnetic cloud chamber. In 1932 Anderson discovered the positron in the course of cosmic-ray interaction studies and one year later succeeded in producing positrons by gamma irradiation. In 1936 he participated in the discovery of the muon, an elementary particle about 207 times as massive as the electron.

Anderson, Elizabeth Garrett (b. June 9, 1836, Aldeburgh, Suffolk, Eng.—d. Dec. 17, 1917, Aldeburgh), English physician who sought the admission of women to professional education, especially in medicine.

Refused admission to medical schools, Anderson began in 1860 to study privately with accredited physicians and in London hospitals and was licensed to practice in 1865 by the Society of Apothecaries. She was appointed (1866) general medical attendant to St. Mary's Dispensary, later the New Hospital for Women, where she worked to create a medical school for women. In 1918 the hospital was renamed Elizabeth Garrett Anderson Hospital in her honour.

Anderson received the M.D. degree from the University of Paris in 1870, and in 1908 she became the first woman mayor of Aldeburgh.

Anderson, Dame Judith, original name FRANCES MARGARET ANDERSON (b. Feb. 10, 1898, Adelaide, S.Aus., Australia—d. Jan. 3, 1992, Santa Barbara, Calif., U.S.), Australian-born stage and motion-picture actress.

Anderson was only 17 years old when she made her stage debut in 1915 in Sydney and 20 when she first appeared in New York City. After her first major success in New York in 1924 in *Cobra*, she went on to appear as Nina Leeds in Eugene O'Neill's *Strange Interlude* (1928) and as Lavinia in O'Neill's *Mourning Becomes Electra* (1932), among other productions. Her interpretation of Gertrude opposite John Gielgud as *Hamlet* (1936), of Lady Macbeth in the London (1937) and New York (1941) productions of *Macbeth*, and in the title role of Robinson Jeffers' version of *Medea* (1947) are considered the pinnacles of her stage career. Anderson specialized in character portrayals and was at her best in roles of great dramatic intensity.

Anderson also appeared in almost 30 motion pictures, typically playing an evil or sinister matriarchal figure. Among her best-known roles are Mrs. Danvers in *Rebecca* (1940) and Ann Treadwell in *Laura* (1944). Her other films include *King's Row* (1941), *Edge of Darkness* (1943), and *The Strange Love of Martha Ivers* (1946). In 1960 she was made Dame Commander of the British Empire.

Anderson, Laurie (b. June 5, 1947, Wayne, Ill., U.S.), American performance artist, composer, and writer whose work explores a remarkable range of media and subject matter.

Anderson began studying classical violin at

five years of age. In 1966 she moved to New York City, where she attended Barnard College (B.A., 1969) and Columbia University (M.F.A., 1972). In *Automotive* (1972), a representative early performance piece, she orchestrated car horns at the Town Green in Rochester, Vt.

Anderson came to rely on a driving rock beat as a backdrop to many of her word-oriented pieces. She released a series of recordings before producing a massive four-part multimedia extravaganza, *United States I-IV*. First performed at the Brooklyn Academy of Music in 1983, it ran for more than six hours and employed music and more than 1,200 photos, cartoons, and films. Also in 1983 Anderson collaborated on *Set and Reset* with visual artist Robert Rauschenberg and choreographer Trisha Brown, whose dance company premiered the piece. She continued to record throughout the 1980s.

In 1994 a book of her work was published entitled *Stories from the Nerve Bible: A Retrospective, 1972-92*. A year later, Anderson embarked on a multimedia tour entitled *The Nerve Bible*, in which she read excerpts from the retrospective book and incorporated elements of music, comedy, illusion, dance, film, songs, and a simulated tornado into her performance. Anderson next toured in 1999 with *Songs and Stories from Moby Dick*, a multimedia, musical event.

Anderson, Lindsay, in full LINDSAY GORDON ANDERSON (b. April 17, 1923, Bangalore, India—d. Aug. 30, 1994, near Angoulême, France), English critic and stage and motion-picture director.

Anderson received a degree in English from the University of Oxford and in 1947 became a founding editor of the film magazine *Sequence*, which lasted until 1951. Anderson began directing in 1948, making documentaries for an industrial firm, and in 1955 he won an Academy Award for his short documentary *Thursday's Children*. In 1956 he coined the term Free Cinema to denote that movement in the British cinema inspired by John Osborne's play *Look Back in Anger* (1956). Anderson and other members of the movement allied themselves with left-wing politics and took their themes from contemporary urban working-class life.

Anderson's first feature-length motion picture, *This Sporting Life* (1963), adapted by the English writer David Storey from his novel, is about a brutish miner who succeeds as a professional rugby player but who fails in love. The film is a classic of the British social realist cinema of the 1960s. Anderson directed productions at the Royal Court and other theatres before making his next film, *If . . .* (1968), in which three English students violently rebel against the conformity and social hypocrisy of their boarding school.

Anderson went on to direct numerous film adaptations of Storey's plays, in addition to other films, throughout the 1970s and '80s.

Anderson, Marian (b. Feb. 27, 1897, Philadelphia, Pa., U.S.—d. April 8, 1993, Portland, Ore.), American singer, one of the finest contraltos of her time.

Born of poor black parents, Anderson received her earliest musical training in the choir of the Union Baptist Church, which she joined when she was six, already having displayed a remarkable voice. Her church raised enough money for her to take private voice lessons.

In 1925 her teacher entered her in a contest for an appearance at Lewisohn Stadium in New York City with the New York Philharmonic Orchestra. She was placed first among 300 competitors. She had already made several concert tours and, despite struggles against

poverty and racial discrimination, was beginning to make a name for herself. Real success came after several trips to Europe between 1925 and 1935, during which time she expanded and deepened her experience as a performer. After her return to New York City in 1935 she achieved even greater success.

In 1939 the Daughters of the American Revolution (DAR) refused to allow Anderson to sing at Constitution Hall in Washington, D.C. A great public outcry followed; Eleanor Roosevelt and other prominent women resigned

Marian Anderson
By courtesy of RCA Records

from the DAR, and a group of citizens arranged a concert held on April 9, 1939, at the Lincoln Memorial that drew an audience of 75,000. She was asked to sing at the White House and was the first black to sing at the Metropolitan Opera in New York City, making her debut in 1955 as Ulrica in Verdi's *Un ballo in maschera* (*A Masked Ball*).

She was acclaimed for her work in behalf of black people and for her warmth of personality as well as for her vocal and interpretative powers. As a singer, her outstanding characteristics were wide range, richness and purity of tone, and mastery of a variety of styles. She wrote an autobiography, *My Lord, What a Morning* (1957), and retired in 1965. She received many honours and awards, including the U.S. National Arts Medal (1986).

Anderson, Mary (b. July 28, 1859, Sacramento, Calif., U.S.—d. May 29, 1940, Broadway, Worcestershire, Eng.), American actress who achieved great popularity because of her exceptional beauty and highly successful publicity.

Acclaimed by the public from the time of her debut in Louisville, Ky., at the age of 16, Anderson remained popular throughout her career despite critics' complaints that she lacked feeling. Among her most famous roles were Galatea in W.S. Gilbert's *Pygmalion and Galatea*; Clarice in his *Comedy and Tragedy*, written especially for her; Hermione and Perdita in her own arrangement of William Shakespeare's *Winter's Tale*; Lady Macbeth in *Macbeth*; and Ion in Sir Thomas Noon Talfourd's *Ion*. In 1889 she suffered a nervous breakdown and temporarily retired, settling in England in 1890. She returned to the stage in 1903 and remained active in the theatre until after World War I. She wrote *A Few Memories* (1896) and *A Few More Memories* (1936).

Anderson, Maxie, byname of MAX LEROY ANDERSON (b. Sept. 10, 1934, Sayre, Okla., U.S.—d. June 27, 1983, near Bad Brückenau, W.Ger.), balloonist who, with Ben Abruzzo and Larry Newman, made the first transatlantic balloon flight and, with his son Kristian, made the first nonstop trans-North American balloon flight.

Anderson entered the Missouri Military Academy, Mexico, Mo., at the age of eight and throughout his schooling worked sum-

mers with his father, a pipeline builder. Anderson held a pilot's license at the age of 15, having lied about his age. By the age of 29 he owned his own mining company in Albuquerque, N.M. He began flying hot-air balloons in New Mexico, alone and with his friend Ben Abruzzo, who was also a light-aircraft flyer (planes, gliders, and helicopters). In 1977 they decided to attempt the transatlantic flight in honour of the 50th anniversary of Charles Lindbergh's flight to Le Bourget field near Paris. Ed Yost, balloonist and balloon builder, whose transatlantic flight had failed in 1958, built the *Double Eagle*, a helium balloon, for them and trained them to fly it. They launched the balloon near Marshfield, Mass., on Sept. 9, 1977, but had to set down off the coast of Iceland on September 13. In 1978 a third crew member was added, Larry Newman, head of the Electra Flyer Corporation, a maker of hang gliders, who applied his expertise to the building of the *Double Eagle II*. On August 11 it was launched from Presque Isle, Maine, and landed near Miserey, France, on August 17.

On May 8, 1980, Anderson and his son Kristian launched the helium balloon *Kitty Hawk* from Fort Baker, Calif., and landed, on May 12, at Sainte-Félicité, Que., Can., the first trans-North American nonstop balloon flight.

Anderson was killed in an accident during a balloon race.

Anderson, Maxwell (b. Dec. 15, 1888, Atlantic, Pa., U.S.—d. Feb. 28, 1959, Stamford, Conn.), prolific playwright noted for his efforts to make verse tragedy a popular form.

Anderson was educated at the University of North Dakota and Stanford University. He collaborated with Laurence Stallings in the World War I comedy *What Price Glory?* (1924), his first hit, a realistically ribald and profane view of World War I. *Saturday's Children* (1927), about the marital problems of a young couple, was also very successful. Anderson's prestige was increased by two ambitious historical dramas in verse—*Elizabeth the Queen* (1930) and *Mary of Scotland* (1933)—and by a success of a very different nature, his humorous Pulitzer Prize-winning prose satire, *Both Your Houses* (1933), an attack on venality in the U.S. Congress. He reached the peak of his career with *Winterset* (1935), a

Maxwell Anderson
Brown Brothers

poetic drama set in his own times. A tragedy inspired by the Sacco and Vanzetti case of the 1920s and set in the urban slums, it deals with the son of a man who has been unjustly condemned to death, who seeks revenge and vindication of his father's name. *High Tor* (1936), a romantic comedy in verse, expressed the author's displeasure with modern materialism. Collaborating with the German refugee composer Kurt Weill (1900–50), Anderson also wrote for the musical theatre a play based on early New York history, *Knickerbocker Holiday* (1938), and *Lost in the Stars* (1949), a dramatization of Alan Paton's South African novel *Cry, the Beloved Country*. His last play, *The Bad Seed* (1954), was a dramatization of William March's novel about an evil child.

Anderson, Philip W., in full PHILIP WARREN ANDERSON (b. Dec. 13, 1923, Indianapolis, Ind., U.S.), physicist who won a Nobel Prize for his part in the development of advanced electronic circuitry.

Educated at Harvard University, Anderson received his doctorate in 1949. From 1949 to 1984 he worked at Bell Telephone Laboratories in Murray Hill, N.J. From 1967 to 1975 he was professor of theoretical physics at the University of Cambridge, and from 1975 he taught at Princeton University. For his research in solid-state physics, which made possible the development of inexpensive electronic switching and memory devices in computers, he was awarded jointly with John H. Van Vleck and Sir Nevill F. Mott the 1977 Nobel Prize for Physics. In 1982 he was awarded the National Medal of Science.

His writings include *Concepts of Solids* (1963) and *Basic Notions of Condensed Matter Physics* (1984). Anderson was a certified first degree-master of the Japanese board game Go.

Anderson, Richard Heron (b. Oct. 7, 1821, Statesburg, S.C., U.S.—d. June 26, 1879, Beaufort, S.C.), Confederate general in the American Civil War.

Anderson graduated from the U.S. Military Academy at West Point in 1842 and won the brevet of first lieutenant in the Mexican War, becoming first lieutenant in 1848 and captain in 1855; he took part in the following year in the Kansas troubles. At the outbreak of the Civil War in 1861, he resigned from the U.S. Army and entered the Confederate service as a brigadier general, being promoted major general on July 14, 1862. Except for a few months spent with the army under Braxton Bragg in 1862, Anderson's service was wholly in the Army of Northern Virginia under General Robert E. Lee.

In the Wilderness campaign, in May 1864, he succeeded to the command of the 1st Corps when Longstreet was wounded. After saving Spotsylvania by a brilliant night march on May 7–8, at the outset of the punishing Battle of Spotsylvania Courthouse, Anderson was given the rank of temporary lieutenant general. He later participated in the defense of Petersburg and Richmond. After the war Anderson became a railroad official in South Carolina and then state phosphate inspector.

Anderson, Sherwood (b. Sept. 13, 1876, Camden, Ohio, U.S.—d. March 8, 1941, Colon, Panama), author who strongly influenced American writing between World Wars I and II, particularly the technique of the short story. His writing had an impact on such notable writers as Ernest Hemingway and William Faulkner, both of whom owe the first publication of their books to his efforts. His prose style, based on everyday speech and derived from the experimental writing of Gertrude Stein, was markedly influential on the early Hemingway—who parodied it cruelly in *Torrents of Spring* (1926) to make a clean break and become his own man.

One of seven children of a day labourer, Anderson attended school intermittently as a youth in Clyde, Ohio, and worked as a newsboy, house painter, farmhand, and racetrack helper. After a year at Wittenberg Academy, a preparatory school in Springfield, Ohio, he worked as an advertising writer in Chicago until 1906, when he went back to Ohio and for the next six years sought—without success—to prosper as a businessman while writing fiction in his spare time. A paint manufacturer in Elyria, Ohio, he left his office abruptly one day in 1912 and wandered off, turning up four days later in Cleveland, disheveled and mentally distraught. He later said he staged this episode to get away from the business world and devote himself to literature.

Anderson went back to his advertising job in Chicago and remained there until he be-

gan to earn enough from his published work to quit. Encouraged by Dreiser, Floyd Dell, Carl Sandburg, and Ben Hecht—leaders of the Chicago literary movement—he began to contribute experimental verse and short fiction to *The Little Review*, *The Masses*, the *Seven Arts*, and *Poetry*. Dell and Dreiser arranged the publication of his first two novels, *Windy McPherson's Son* (1916; rev. 1921) and *Marching Men* (1917), both written while he was still a manufacturer. *Winesburg, Ohio* was his first mature book and made his reputation as an author. Its interrelated short sketches and tales are told by a newspaper reporter-narrator who is as emotionally stunted in some ways as the people he describes. His novels include *Many Marriages* (1923), which stresses the need for sexual fulfillment; *Dark Laughter* (1925), which values the "primitive" over the civilized; and *Beyond Desire* (1932), a novel of Southern textile mill labour struggles.

His best work is generally thought to be in his short stories, collected in *Winesburg, Ohio*, *The Triumph of the Egg* (1921), *Horses and Men* (1923), and *Death in the Woods* (1933). Also valued are the autobiographical sketches *A Story Teller's Story* (1924), *Tar: A Midwest Childhood* (1926), and the posthumous *Memoirs* (1942; critical edition 1969). A selection of his *Letters* appeared in 1953.

Andersonville, village, Sumter County, southwest central Georgia, U.S., best known as the site of a Confederate military prison from February 1864 until May 1865 during the American Civil War. The Andersonville National Cemetery—consisting of 84 acres with the prison site—contains the graves of 12,912 Union prisoners who died at Andersonville, as well as a few thousand graves of other military persons interred there since 1865.

In the summer of 1863 the U.S. federal authorities ended an agreement under which Union and Confederate captives were exchanged; the resultant increased number of Union prisoners of war confined in Richmond constituted a danger to the Confederacy and seriously pressed upon the food supply. In November 1863, Confederate authorities selected the Andersonville site, through which ran a stream, and began to construct a stockade of 16.5 acres. Prisoners began to arrive in February 1864, before the prison was completed and before adequate supplies had been received, and in May their number amounted to about 12,000. In June the stockade was enlarged so as to include 26 acres, but the congestion was only temporarily relieved, and in August the number of prisoners exceeded 32,000. No shelter had been provided for the inmates: the first arrivals made rude sheds from the debris of the stockade; the others made tents of blankets and other available pieces of cloth or dug pits in the ground. Owing to the slender resources of the Confederacy, the prison was frequently short of food, and even when food was sufficient in quantity, it was of a poor quality and poorly prepared because of the lack of cooking utensils. The water supply, deemed ample when the prison was planned, became polluted under the congested conditions. The medical staff was inadequate and poorly provisioned. During the summer of 1864 the prisoners suffered greatly from hunger, exposure, and disease, and in seven months about a third of them died. In the autumn of 1864, after the capture of Atlanta, all the prisoners who could be moved were sent to Millen, Ga., and Florence, S.C. At Millen better arrangements prevailed, and when, after Gen. W.T. Sherman began his march to the sea, the prisoners were returned to Andersonville, the conditions there were somewhat improved. During the war 49,485 prisoners were received at the Andersonville prison, and of these about 13,000 died.

Conditions in Andersonville were utilized as propaganda material in the North, where Secretary of War Edwin M. Stanton ordered retaliation on Confederates held in Union prisons. After the war, Capt. Henry Wirz, commander of the prison, was tried by a military commission and on Nov. 10, 1865, was hanged.

Anderssen, Adolf (b. July 6, 1818, Breslau, Prussia—d. March 13, 1879, Breslau), Chess master considered the world's strongest player from his victory in the first modern international tournament (London, 1851) until his defeat (1858) by Paul Morphy in match play and, again, after Morphy's retirement (c. 1861) until his defeat by Wilhelm Steinitz (1866). Anderssen was noted for his ability to discover combination plays calculated to force an immediate decision. One of his famous games was dubbed "the Immortal Game." Anderssen studied mathematics and philosophy and taught mathematics and German at the Friedrichs Gymnasium in Breslau.

Andersson, Dan(iel) (b. April 6, 1888, Skatölösbergett, Swed.—d. Sept. 20, 1920, Stockholm), poet and prose writer, an early practitioner of working class literature who became one of the few popular Swedish poets.

Born to a poor family, he was a woodsman and charcoal burner before he became a temperance lecturer. His first two published volumes, which made the charcoal burners and, incidentally, himself famous, were *Kolarhistorier* (1914; "Charcoal Burner's Tales") and *Kolvaktarens visor* (1915; "Charcoal Watcher's Songs"); a selection was translated into English in *Charcoal Burner's Ballad & Other Poems*, (1943). He published one more book of poems during his lifetime, *Svarta ballader* (1917; "Black Ballads"), and two autobiographical novels, *De tre hemlösa* (1918; "The Three Homeless Ones") and *David Ramms arv* (1919; "David Ramm's Heritage"). A considerable part of his verse and prose was published after his death in *Efterskörd* (1929; "Late Harvest") and *Tryck och Otrycke* (1942; "Printed and Unprinted").

Andersson, Johan Gunnar (b. July 3, 1874, Knista, Swed.—d. Oct. 29, 1960, Stockholm), Swedish geologist and archaeologist whose work laid the foundation for the study of prehistoric China. In 1921, at a cave near Chouk'ou-tien in the vicinity of Peking, on the basis of bits of quartz that he found in a limestone region, he predicted that a fossil man would be discovered. Six years later the first evidence of the fossil hominid *Sinanthropus* (Peking man) was found there.

He first went to China in 1914 as a technical adviser on oil and coal resources. He immediately became interested in fossil remains and eventually devoted himself to archaeological exploration. In 1921, at Yang-shao, Honan Province, he found elegant painted pottery that provided the first evidence of Neolithic culture in China. Within a year he discovered many other comparable sites across the vast stretch of the Yellow River Valley of northern China and published a preliminary account of his findings, *An Early Chinese Culture* (1923). His study helped to define what is now termed Yang-shao culture, which he related to the cultures of southwest Asia and dated at about 3000–1500 BC. Of his bronze findings, none could be dated earlier than about 1300 BC, during the period of the Shang dynasty. He described his progress as an archaeologist in *Children of the Yellow Earth: Studies in Prehistoric China* (1934).

Andes Mountains, also called THE ANDES, Spanish CORDILLERA DE LOS ANDES, OR LOS ANDES, great mountain system of South America and one of the great natural features of the globe, stretching the length of the South American continent from Lago (Lake) de Maracaibo in the north to the Tierra del Fuego archipelago in the south.

The following article summarizes information about the Andes Mountains; for full details, see MACROPAEDIA: South America.

Occupying significant portions of seven countries, the Andes may be separated, from north to south, into six major subdivisions: the Venezuelan Cordillera, the Colombian cordilleras, the Ecuadorian Andes, the Peruvian Andes, the Central Andes, and the Patagonian Andes. The Venezuelan Cordillera separates the Orinoco Basin from Lago de Maracaibo and the Caribbean Sea as it extends southwestward to join the eastern segment of the Colombian ranges (Cordillera Oriental). The Colombian cordilleras, consisting of three or four ranges, extend finger-like northeastward from the Ecuadorian border to dominate the Colombian landscape. The Ecuadorian Andes is composed of a large plateau that runs from north to south and extends between two chains of high volcanic peaks (the Cordilleras Occidental and Central). The cordilleras of the Peruvian Andes turn generally southeastward along three distinctive ranges, dominated for the most part by the western Cordillera Occidental. The Peruvian and the Central Andes merge and widen at the Altiplano (among the world's largest interior basins, extending across the Peruvian and Bolivian frontier) which contains the 110-mi-long Lake Titicaca, the highest navigable lake in the world. Before narrowing again southward, the Andes enter northern Argentina, occupying its northwestern provinces. The Patagonian Andes, forming some of the most rugged terrain of the entire South American cordilleras, provide the boundary between Chile and Argentina from Bolivia south through Tierra del Fuego. The highest peak of the Andes, Mt. Aconcagua, rises to 22,831 ft (6,959 m) above sea level within these southern ranges.

andesite, any member of a large family of rocks that occur in most of the world's volcanic areas. Andesites occur mainly as surface deposits and, to a lesser extent, as dikes and small plugs. Many of the deposits are not normal lava flows but rather flow breccias, mudflows, tuffs, and other fragmental rocks; the peperino near Rome and the trass of the Eifel district in Germany are examples. Not only the Andes, where the name was first applied to a series of lavas, but most of the cordillera (parallel mountain chains) of Central and North America consist largely of andesites. The same rock type occurs in abundance in volcanoes along practically the entire margin of the Pacific Basin. The volcanoes Montagne Pelée, the Soufrière of St. Vincent, Krakatoa, Bandai-san, Popocatepetl, Fuji, Ngauruhoe, Shasta, Hood, and Adams have emitted great quantities of andesitic rock.

Andesite most commonly denotes fine-grained, usually porphyritic rocks; in composition these correspond roughly to the intrusive igneous rock diorite and consist essentially of andesine (a plagioclase feldspar) and one or more ferromagnesian minerals, such as pyroxene or biotite. Smaller amounts of sanidine, a potassium-rich feldspar, may be present. The larger crystals of feldspar and ferromagnesian minerals are often visible to the naked eye; they lie in a finer groundmass, usually crystalline, but sometimes glassy.

There are three subdivisions of this rock family: the quartz-bearing andesites, or dacites, sometimes considered to be a separate family; the hornblende- and biotite-andesites; and the pyroxene-andesites. The dacites (*q.v.*) contain primary quartz, which may appear in small blebs or crystals or only as minute interstitial grains in the groundmass. The hornblende- and biotite-andesites are comparatively rich in feldspar and are usually pale pink, yellow, or gray. Pyroxene-andesites are the commonest

type of andesite and occur in amounts comparable to basalt. They are darker, denser, more basic rocks.

The geographic line that separates the andesite-dacite-rhyolite rock association of the Pacific margin from the olivine-basalt-trachyte rock association of the Pacific Basin islands is known as the andesite line. This line, mainly determined petrographically, runs on the western side of the Pacific from Alaska to east of New Zealand via Japan, the Marianas, the Palau Islands, the Bismarck Archipelago, the Fiji Islands, and the Tonga Islands. East of the Pacific the line is less well defined but probably follows the west coasts of North and South America; the line's position in the South Pacific has not been determined.

Andhra Pradesh, constituent state of India, located in the southeastern part of the Indian subcontinent. It is bounded by the states of Tamil Nādu to the south, Karnāṭaka to the west, and Mahārāshtra, Madhya Pradesh, and Orissa to the north. The Bay of Bengal bounds the state to the east. Its name derives from the Andhra people who have long inhabited the area and have their own language, Telugu.

A brief treatment of Andhra Pradesh follows. For full treatment, see *MACROPAEDIA*: India. Many dynasties ruled in the area, dating back to the 3rd century BC, and Buddhism flourished there. Rulers during the 12th and 13th centuries expanded Andhra power, which

Coastline near Vishakhapatnam, Andhra Pradesh, India

© Ashvin Mehta/Dinodia Picture Agency

reached its peak in the 16th century. The Andhras came under British influence in the 17th century, then played a decisive role in the rise of Indian nationalism in the 19th. Pride in their historical and linguistic achievements led them to demand a separate state, and the state in its present form dates from 1956.

Three main physiographic regions characterize Andhra Pradesh: a coastal plain to the east, running from the Bay of Bengal inland to the mountain ranges; the Eastern Ghāts mountain range; and a plateau to the west of the Ghāts. The deltas of the Godāvāri and Krishna rivers in the central part of the alluvial coastal plains contain especially fertile soil.

Andhra Pradesh has three seasons. Summer lasts from March to June. A period of tropical rains follows from July to September, and winter begins in October and concludes in February. Maximum and minimum temperatures range from 74° to 82° F (23° to 28° C) and from 50° to 53° F (10° to 12° C), respectively, with summers cooler and winters colder on the plateau. The southwest monsoon causes the most rainfall, which ranges from a maximum of 55 inches (1,400 mm) to 20 inches (500 mm) annually. Rainfall is heavy in the coastal area.

Nearly nine-tenths of the people of Andhra

Pradesh speak Telugu, and about one-twelfth speak Urdū, largely the language of the Muslim population. The remaining groups consist of people speaking border-area languages, including Hindi, Tamil, Kannaḍa, Marāṭhī, and Oṛiyā, and such tribal languages as Lamani.

Some 70 percent of the population is engaged in agriculture, which accounts for about half of the state's income. About half of the agricultural area is devoted to producing food grains, yielding some 9 million tons of rice alone each year. Andhra Pradesh produces most of the Virginia tobacco of the country and is one of the largest rice-producing states in India. Other crops include cotton and sugarcane, together with chili peppers, sorghum, pulses (legumes), and castor beans. Forested areas yield timber and forest products.

Andhra Pradesh contains such minerals as asbestos, mica, manganese, barite, coal, limestone, and low-grade iron ore. Even though it has become one of the most highly industrialized states in India, manufacturing still accounts for only a small share of its income. Government-run industries include shipbuilding and aeronautics and the manufacture of electrical equipment, machine tools, cement, and drugs; private-sector activities include chemical and textile production. As a means of stimulating industry, Andhra Pradesh increased its hydroelectric and thermoelectric generating capacity. Significant natural-gas deposits have been discovered in the deltas of the Godāvāri and Krishna rivers. The rail system serves much of the state, and there are four major airports, located at Hyderābād (the capital), Vijayawāda, Tirupati, and Vishakhapatnam.

The arts and literature of Andhra Pradesh thrive under both state and private sponsorship. The *kuchipudi* dance style, which includes singing, is unique in the Indian tradition, and Telugu—one of the four literary languages of the Dravidian family—occupies a prestigious position among Indian languages. Folk culture predominates in rural areas, through such forms as minstrel-ballad performances, puppet shows, and mythological storytelling.

Andhra Pradesh has universities at Hyderābād, Waltair, Wārangal, Guntur, Anantpur, and Tirupati, with numerous affiliated colleges. An agricultural university is at Hyderābād. Various industrial-training institutes provide vocational education. Area 106,204 square miles (275,068 square km). Pop. (1991) 66,508,008.

Andijon, also spelled *ANDIZHAN*, or *ANDIŽAN*, city, extreme eastern Uzbekistan. Andijon lies in the southeastern part of the Fergana Valley. The city, which stands on ancient deposits of the Andijon River, dates back at least to the 9th century. In the 15th century it became the capital of the Fergana Valley and, being on the Silk Road caravan route to China, its chief centre of trade and handicrafts. In the 18th century it became part of the khanate of Kokand, and in 1876 Andijon was captured by the Russians. In 1898 it was the scene of an abortive native rebellion against tsarist rule. Andijon is subject to frequent earth tremors and was leveled by an earthquake in 1902 that took more than 4,000 lives.

Andijon is now a road and rail junction and has engineering, electrotechnical, textile, and food-processing industries. Its cultural assets include teacher-training, medical, and cotton-growing institutes, an Uzbek theatre of musical drama and comedy, a puppet theatre, and a museum.

The surrounding area is the most densely populated part of Uzbekistan. Several major irrigation canals provide water for crops of cotton, grapes, and fruit. The region is also

the main petroleum-producing area of Uzbekistan. Other industries are mainly concerned with processing raw cotton and other agricultural products. Pop. (1991 est.) 298,300.

andiron, one of a pair of horizontal iron bars upon which wood is supported in an open fireplace. The oldest of fireplace furnishings, andirons were used widely from the Late Iron Age. The andiron stands on short legs and usually has a vertical guard bar at the front to prevent logs from rolling off, thus giving it a somewhat doglike appearance (hence the alternative name, *fire dog*). It was ordinarily fitted with a guard at each end when intended for use in a central open hearth, which went out of general use in the late 14th century. The guard was often cast in the form of a statue or with elaborate decoration. Plain andirons, called *cobirons*, with ratcheted guards holding brackets for spits, were used in the kitchen.

Andō Hiroshige (Japanese artist): see *Hiroshige*.

Andō Kichijirō, also called *ANDŌ KATSUSABURŌ* (Japanese painter): see *Shiba Kōkan*.

Andō Shōeki (fl. c. 1750), Japanese philosopher considered to be one of the forerunners of the 19th-century movement to restore power to the emperor. He was also one of the first Japanese to study European thought.

Andō was a native of Akita. He practiced medicine at Hachinohe, in the present Aomori prefecture, but became prominent as a social thinker in the 1750s. Andō was critical of the feudal society of the Tokugawa shogunate. In his work *Jinen shin'ei dō* ("The True Way of Administering [the society] According to Nature"), he called for the abolition of the warrior class and a return to agrarian egalitarian society, which was to be administered directly by the national government.

Andocides (b. c. 440 BC—d. after 391), Athenian orator and politician.

Born into one of the most prominent Athenian families, Andocides was imprisoned on suspicion of having taken part in the mutilation of the sacred busts called herms shortly before the departure of Athens' military expedition to Sicily in 415. These mutilations caused a general panic, and Andocides was induced to turn informer on the guilty persons. Although the historian Thucydides was not convinced that Andocides' testimony was genuine, it was accepted, and those whom he implicated were condemned to death. Andocides went into exile and returned under the general amnesty of 403, when the democracy was restored. In 400 he was tried for impiety, but he had powerful support and was acquitted. In 392, during the Corinthian War, he went with three colleagues to negotiate peace with Sparta, but Athens rejected the terms and exiled the ambassadors. Although an unsuccessful politician, Andocides had a gift for vivid narrative. Three of his speeches survive: "On His Return"; "On the Mysteries," his defense in 400; and "On the Peace" (392).

Andong, city, North Kyōngsang *do* (province), east-central South Korea. It lies 215 miles (345 km) from the mouth of the Nakdong River, at the terminus of its navigable section, near a multipurpose dam. The city has been in existence since the Three Kingdoms period (beginning c. 57 BC) under various names, and since the Koryō period (935–1392) it has been known by its present name. Until the end of the Chosōn (Yi) dynasty (1392–1910), it was the local administrative centre, producing a number of scholars and political leaders. The city's traditional domestic products are alcoholic spirits (Andong-Soju), hemp cloth (Andong-Po), and silk. Andong is the seat of a national university (1979). Pop. (1990) 116,958.

Andong (China): see *Tan-tung*.

Andorra (Catalan and Spanish), French **ANDORRE**, officially **PRINCIPALITY OF ANDORRA**, or **PRINCIPAT D'ANDORRA**, small independent European coprincipality situated among the south slopes of the Pyrenees Mountains and bounded by Spain (south and west) and by France (north and east). The capital is **Andorra-la-Vella**.

Andorra's independence is traditionally ascribed to Charlemagne, who recovered the region from the Muslims in AD 803, and to his son Louis I the Pious, who granted the inhabitants a charter of liberties. Charlemagne's grandson, Charles II, granted Andorra to the counts of Urgel, from whom it passed to the bishops of Urgel. Andorra's seven-century-old dual allegiance to two princes, one in Spain and one in France, originated in the late 13th century in a proprietary quarrel between the (Spanish) bishops of Urgel and the (French) heirs to the countship of Urgel. Andorra was subsequently governed jointly by representatives of the Spanish bishop of Urgel and of the French head of state, each of whom received an annual payment of a token tribute. This feudal system of government, the last in Europe, remained intact until 1993, when a

Andorra

constitution was adopted that greatly reduced the power of the coprinces and established separate executive, legislative, and judicial branches of government.

The coprincipality has traditionally had a strong affinity with the region of Catalonia in northern Spain. Andorra's official language is Catalan. Its institutions are based in Catalan law, and a large proportion of the Spanish immigrants (or their descendants) in Andorra are Catalan. Most Andorrans are Roman Catholic, and the principality is part of the diocese of the See of Urgel. Nearly two-thirds of the population is urban.

Andorra consists of a cluster of mountain valleys whose streams unite to form the Valira River. With only about 2 percent of the land cultivable, the traditional economy centred on the pasturing of sheep and the harvesting of modest quantities of tobacco, rye, wheat, olives, grapes, and potatoes. Industry was limited to processing these products and to handicrafts. From the 1950s tourism became one of Andorra's chief industries, based on the scenic attractions of the mountains and the area's excellent opportunities for winter sports. Owing to the lack of customs duties and low or nonexistent taxes, Andorra in the late 20th century also became an important international centre of retail trade that attracted millions of shoppers from all over Europe with its duty-free imported consumer goods. There is no national monetary unit, and both French and Spanish currencies are used. No railway system exists, but good roads link Andorra with France and Spain.

Historically, the coprinces (the French pres-

ident and the bishop of Urgel) represented Andorra internationally and jointly headed the government through their delegates. The elected members of the General Council of the Valleys saw to internal administration and functioned as both an informal legislature and a cabinet headed by a prime minister. The 1993 constitution, approved by Andorran voters in a referendum, transferred most of the coprinces' powers to the General Council and its cabinet, which became a true national parliament elected by universal suffrage. The government was newly empowered to raise revenues through taxation, an independent judiciary was created, citizens were given the right to form political parties and trade unions, and Andorra achieved control of its foreign policy and could now enter international organizations. The coprinces remained the constitutional heads of state, though largely in name only. Pop. (2002 est.) 66,400.

Andorra-la-Vella (Catalan: "Andorra the Old"), French **ANDORRE-LA-VIEILLE**, Spanish **ANDORRA-LA-VIEJA**, town, capital of the independent coprincipality of Andorra. It lies near the confluence of the Valira and the Valira del Norte rivers in the narrow Gran Valira valley, on the southern slopes of the Pyrenees.

Andorra-la-Vella long remained relatively isolated from the outside world. Its modernization began in the 1930s with the construction of carriage roads, and its population increased after World War II as a result of the growth of the tourist industry. In the 1960s and '70s Andorra-la-Vella was transformed from a rustic town into a busy commercial centre catering to shoppers and tourists. Winter sports areas are nearby. Because of Andorra's duty-free status, the town is now primarily a retail shopping centre for goods imported from elsewhere in Europe and from Asia. The General Council (Andorra's parliament) meets in Andorra-la-Vella. The town is connected by road to the Spanish and French frontiers and shares in both cultures. Pop. (2000 est.) 21,189.

Andover, market town, Test Valley district, county of Hampshire, England. It lies among chalk hills on the River Anton, a tributary of the Test, about 14 miles (22 km) northwest of Winchester and about 17 miles (27 km) northeast of Salisbury. The area is rich in prehistoric earthworks and tumuli. The witan (Anglo-Saxon national council) met there.

Andover's earliest-known charter was granted in 1175. In the 14th century the town had a sheep fair, a woolen industry, and an iron market and also manufactured parchments and silk fabrics. It is now the centre of a large agricultural district; watercress is grown, there are flour mills, timber yards, and printing works, and agricultural equipment and plastics are manufactured. Andover Grammar School was founded in 1571. At Enham, north of Andover, is a village founded for disabled former servicemen after World War I. There are many military and air force establishments in the area, including the Royal Air Force Staff College. Pop. (1991) 34,647.

Andover, town ("township"), Essex county, northeastern Massachusetts, U.S. It lies along the Merrimack River, just south of Lawrence. It was settled in 1642, incorporated in 1646, and named for Andover, Eng., home of many of the early colonists. A council-manager form of government became effective in 1959.

Andover is both an industrial and an educational centre. Textile mills were established there in 1813, and woolen and worsted goods are still important products. Its manufactures now also include electronic parts, rubber and canvas footwear, and chemicals. The town's two noted educational institutions—Phillips Academy, founded in 1778 and one of the nation's oldest boarding schools for boys, and Abbot Academy for girls (1829)—merged in 1973. North Andover, seat of Merrimack Col-

lege (1947), was separated from Andover in 1855. Pop. (2000) 31,247.

Andrada e Silva, José Bonifácio de (b. c. 1763, Santos, Braz.—d. April 6, 1838, Niterói, Braz.), Brazilian statesman who played a key role in Brazil's attainment of independence from Portugal. He is known to Brazilians as the "Patriarch of Independence."

Andrada went to Portugal as a student and became a distinguished scholar there, earning an international reputation as a naturalist and

Andrada e Silva, portrait by an unknown artist

By courtesy of the Arquivo Nacional do Brasil

geologist. He remained in Portugal until he was 56, serving as a professor at the University of Coimbra and as the permanent secretary of the Lisbon Academy. He was deeply influenced by the principles of the Enlightenment.

Returning to Brazil in 1819, Andrada devoted himself to politics and quickly became the leading intellectual advocate of Brazilian independence from Portugal. More importantly, he became the chief adviser to the young prince regent, Dom Pedro (later the emperor Pedro I). He headed the ministry formed in January 1822 by Dom Pedro and supported Pedro in his determination that Brazil should be independent. After Pedro proclaimed Brazil's independence from Portugal (Sept. 7, 1822), Andrada became prime minister of the new empire of Brazil.

In the constituent assembly of 1823, Andrada's liberal political principles led him to oppose Pedro's Portuguese advisers, and consequently Andrada was exiled until 1829. He was then allowed to aid Pedro I once again, and he worked for the imperial cause even after Pedro's abdication (April 7, 1831). He became tutor to the child emperor Pedro II, and the liberal education that he gave Pedro II helped the latter become an effective and enlightened monarch. After being arrested in 1833 for political intrigue, Andrada retired from public life.

Andrade, Mário de, in full **MÁRIO RAUL DE MORAIS ANDRADE** (b. Oct. 9, 1893, São Paulo, Braz.—d. Feb. 25, 1945, São Paulo), writer whose chief importance was his introduction of a highly individual prose style that attempted to reflect colloquial Brazilian speech rather than "correct" Portuguese. He was also important in Brazil's Modernist movement.

Educated at the conservatory in São Paulo, Andrade helped organize what proved to be a key event in the future artistic life of Brazil, the *Semana de Arte Moderna* ("Week of Modern Art"), held in São Paulo in February 1922. His own contribution to the event, a reading of poems drawn from his *Paulicéia Desvairada* (1922; *Hallucinated City*), was greeted by catcalls, but it has since been recognized as the single most significant influence on modern Brazilian poetry.

Andrade's diverse interests and wide knowledge ranged among all the arts and found expression in several. As director of the De-

partment of Culture of São Paulo from 1935 until his death, he organized research into Brazilian folklore and folk music. His own novels reflect his concern for folk themes; *Macunaíma* (1928) is written in his highly idiomatic style in an attempt to recreate actual Brazilian speech.

Andrade's complete poems were collected and published posthumously (*Poesias Completas*, 1955). These, together with his critical writings, continue to influence the arts in Brazil.

A list of the abbreviations used in the MICROPAEDIA will be found at the end of this volume

Andrade, Oswald de, in full JOSÉ OSWALD DE SOUSA ANDRADE (b. Jan. 11, 1890, São Paulo, Brazil—d. Oct. 22, 1954, São Paulo), poet, playwright, and novelist, social agitator and revolutionary, one of the leaders of Brazil's Modernist movement in the arts.

Born into a wealthy and aristocratic family, Andrade traveled extensively in Europe during his youth and there became aware of avant-garde literary trends in Paris and Italy. After his return to São Paulo, where he received his degree in law in 1919, he and Mário de Andrade (no relation) helped organize the *Semana de Arte Moderna* ("Week of Modern Art") at São Paulo in 1922, to introduce the Modernist movement to the public.

Focusing specifically on the nationalistic aspects of Modernism, Andrade, in his literary manifesto *Pau-Brasil* (1925; "Brazil Wood"), called for a rejection of Portuguese social and literary artifice and a return to what he saw as the primitive spontaneity of expression of the indigenous Brazilians, emphasizing the need for modern Brazil to become aware of its own heritage. To this end, he founded the literary movement known as Antropofagia ("Cannibalism"), a splinter group of Modernism, which, although short-lived, proved influential in its emphasis on folklore and native themes.

Intent on bringing about social as well as literary reform in Brazil, Andrade joined the Communist Party in 1931 but left it, disillusioned, in 1945. He remained a controversial figure for his radical political views and his often belligerent outspokenness.

In the years after his death, his novels, especially *Memórias Sentimentais de João Miramar* (1924; "Sentimental Memoirs of João Miramar"), came to be appreciated for their originality of style, rather than solely for their ideological or historical significance.

andradite, calcium-iron garnet, perhaps the most spectacular garnet because of its high dispersion (separation of light into colours), even greater than that of diamond, and refractive index. It is found in various colours, some of the most beautiful being yellowish

Andradite garnet from the Banat region, Romania

By courtesy of the Field Museum of Natural History, Chicago. photograph, John H. Gerard

(termed topazolite, because of its resemblance to topaz) and yellowish green or emerald-green (Uralian emeralds, or demantoid). Titanium may extensively replace both the iron and the silicon, as in schorlomite, or may simply produce a black colour, as in melanite. Andradite is typically found with grossular in contact-metamorphosed limestone. For details of chemistry and occurrence, see garnet.

András (Hungarian personal name): see under Andrew.

Andrássy, Gyula, Count (Gróf), German in full JULIUS, GRAF (COUNT) ANDRÁSSY VON CSIKSZENTKIRÁLY UND KRASZNAHORKA (b. March 3, 1823, Kassa, Hung., Austrian Empire [now Košice, Slovakia]—d. Feb. 18, 1890, Volosco, Istria, Austria-Hungary [now in Croatia]), Hungarian prime minister and

Andrássy; detail of a lithograph by Katzler, 1872

By courtesy of the Bild-Archiv, Österreichische Nationalbibliothek Vienna

Austro-Hungarian foreign minister (1871–79), who helped create the Austro-Hungarian dualist form of government. As a firm supporter of Germany, he created, with the imperial German chancellor Otto von Bismarck, the Austro-German alliance of 1879, which became the cornerstone of Austria's foreign policy until the monarchy's eventual collapse in 1918.

A member of the radical Hungarian reform party under Lajos Kossuth, Andrássy entered the Hungarian Diet in 1847. He commanded a battalion in the revolt against Austria of 1848–49. Fleeing into exile on Hungary's surrender, he was condemned in absentia to death and was hanged in effigy, but he obtained an amnesty in 1857 and returned. Andrássy thereafter supported Ferenc Deák in the negotiations leading to the dualist compromise of 1867. Appointed Hungarian prime minister and defense minister (Feb. 17, 1867), he was largely responsible for the final constitutional negotiations between Austria and Hungary.

Viewing the Slavs as a threat to his country, Andrássy became a staunch supporter of dualism and opposed Karl Siegmund von Hohenwart's scheme (1871) to raise the constitutional status of the lands of the Bohemian crown. He further cultivated relations with Germany as a counterweight to Russia and opposed the destruction of Turkey, which would have resulted in tremendous gains for the Slavic powers. On his insistence, Austria remained neutral during the Franco-German War of 1870–71.

When Emperor Francis Joseph abandoned his policy of revenge against Prussia, Andrássy became Austro-Hungarian foreign minister (Nov. 14, 1871). During his tenure Austria-Hungary's international position was strengthened considerably. He tried to avoid an increase in the monarchy's Slavic population, but, to prevent Russia from profiting alone from the Balkan crisis beginning in 1875, he agreed at the Congress of Berlin (1878) to Austria's occupation of Bosnia and Herzegovina. This act, highly unpopular in both Austria and Hungary, contributed to his decision to resign (Oct. 8, 1879). The previous day, however,

he signed the fateful Austro-German alliance that was to link these two great powers until the end of World War I.

After his retirement, Andrássy remained in public life as a member of Hungary's upper house. His younger son and namesake also became a distinguished Austro-Hungarian political leader.

André (French personal name): see under Andrew, except as below.

André LE CHAPELAIN, Latin ANDREAS CAPPELLANUS (fl. 12th century), French writer on the art of courtly love, best known for his three-volume treatise *Liber de arte honeste amandi et reprobatione inhonesti amoris* (c. 1185; "Book of the Art of Loving Nobly and the Reprobation of Dishonourable Love"). He is thought to have been a chaplain at the court of Marie, Countess of Champagne, daughter of Eleanor of Aquitaine. At Marie's request André wrote the *Liber*. It was translated into French twice during the 13th century; Guillaume de Lorris drew upon it for the *Roman de la rose*. The *Liber* codifies the whole doctrine of courtly love, containing practically all the elements of the cult.

André, John (b. May 2, 1750, London, Eng.—d. Oct. 2, 1780, Tappan, N.Y., U.S.), British army officer who negotiated with the American general Benedict Arnold and was executed as a spy during the U.S. War of Independence (1775–83).

Sent to America in 1774, André became chief intelligence officer to the British commander in chief, General Sir Henry Clinton, in New York City. From May 1779 he carried on a secret correspondence with Arnold, who had become disillusioned with the American cause. In August 1780 Arnold was appointed commandant of the fort at West Point, N.Y.,

which, at a meeting with André on September 21, he agreed to surrender for £20,000.

While returning to New York City, André was captured by three American militiamen; he failed to use the pass that Arnold had given him, and papers concerning West Point were found in one of his boots. A board of officers designated by General George Washington found him guilty of spying and condemned him to death. When General Clinton refused to exchange him for Arnold, who had escaped to British territory, André was hanged. He was mourned on both sides because of his personal charm and literary talent.

Andrea DA BARBERINO (b. c. 1370, Barberino di Val d'Elsa, near Florence [Italy]—d. c. 1432, Florence), ballad singer, prose writer, and compiler of epic tales.

The material for his prose compilation of Charlemagne legends, *I reali di Francia* (1491; modern edition by G. Vandelli, 1892–1900), was drawn for the most part from earlier Italian versions, though the author added much pseudohistorical material and invented many

exciting amplifications. His epic tale *Guerin meschino* (1473), although told also by other writers, is largely of Andrea's own creation. It follows the fortunes of the slave-born hero Guerrino, who emerges strong and unshaken from a multitude of fantastic adventures and dangers to discover his royal parentage, secure his parents' release from prison, marry a Persian princess, and live happily until his death.

Andrea also compiled (and himself recited) such romances as *Aspromonte*, *Le storie Narbonesi* (published 1873–82) and *La storia di Ugone* and *La discesa di Guerino all'inferno* (both 1882).

Andrea DA FIRENZE, also called **ANDREA DI BONAIUTI** (fl. c. 1337–77), Florentine fresco painter whose considerable ability is demonstrated by his works in the church of Sta. Maria Novella in Florence.

his friends as Andreino. With two brief exceptions, his working life was spent in Florence. It is possible that Sarto was apprenticed to a goldsmith and a wood-carver before settling with the painter Raffaellino del Garbo soon after 1500. Raffaellino was a respectable and, in these years, still competitive representative of the traditions of late 15th-century painting, but his influence not unnaturally disappeared rather quickly as Sarto looked about him at the works of Leonardo, Michelangelo, and Fra Bartolommeo. He began to produce independent work about 1506—not precociously. Almost immediately he began a long association with a new church and convent of SS. Annunziata (for which he did frescoes in 1509–14 and 1525), and he moved to a workshop near it in or about 1511. There, for five or six years, he shared the experiences and some-

By 1523 he had a manservant as well as apprentices. Throughout his life he was content to work, when it suited him, for nominal fees, for no remuneration at all, or for only part of a fee offered to him, probably because he was in comfortable circumstances. He would paint for a carpenter or a king. A plague in 1523–24 drove Sarto and his wife to seek security in the Mugello, a valley north of Florence, but the interruption was brief. After the expulsion of the Medici, once more, in 1527, he worked for the republican government of Florence. His "Sacrifice of Isaac," intended as a political present to Francis I, was painted in this period. After the siege of Florence by imperial and papal forces, he succumbed to a new wave of plague and died in his house. He was buried in SS. Annunziata.

Andrea del Sarto's most striking monument is the grisaille (gray monochrome) series of frescoes on the life of St. John the Baptist in the Chiostro dello Scalzo, Florence. Begun about 1511, the work was not completed until 1526, and almost all of it was painted by his own hand, so that it reads like an artistic autobiography covering the greater part of his career. His portraits of his wife, Lucrezia (c. 1513–14, Prado, Madrid; and c. 1522, Staatliche Museen Preussischer Kulturbesitz, Berlin), can be supplemented by many others disguised as Madonnas (e.g., the celebrated "Madonna of the Harpies"), just as his self-portraits in the Uffizi and in the National Gallery of Scotland at Edinburgh (both c. 1528) can be extended by several others, more or less hidden in his paintings from 1511 onward. A badly damaged pair of circular portraits of Andrea and Lucrezia at the Art Institute of Chicago appear to be signed (completed about 1530).

Sarto's style is marked throughout his career by an interest, exceptional among Florentines, in effects of colour and atmosphere and by sophisticated informality and natural expression of emotion. In his early works such as the "Marriage of St. Catherine," the search for the expression of animation and emotion led to an ecstatic and nonidealistic style that proved immensely attractive to a younger generation of painters. Restraint increasing with maturity did not inhibit the achievement of such passionate later works as the "Pietà" (c. 1520), but the mood is always intimate and never rhetorical. In the 1520s his style, as a result of the influence of Michelangelo or of artistic events in Rome, became perceptibly more ideal, more polished, and approximates what may properly be called a grand manner in the last of the Scalzo frescoes, the "Birth of the Baptist" (1526). From first to last, Sarto's integrity as a craftsman, his sheer professionalism, is impressively consistent; and it is characteristic of him that he refused to have his works engraved. His real quality is most vividly revealed, however, where there were no rewards of publicity, in his drawings.

Assessment. The reputation of Sarto has not yet recovered from the discovery, made in the 19th century, that the conventional characterization of his works—"faultless"—could be used as a term of reproach. His drawings are eloquent witness to only one ambition: to make each picture more perfect in terms of composition and craftsmanship than the last. Until the patient pursuit of perfection is thought, once more, to be a proper ideal for a naturally gifted artist, his importance is best presented as that of a great teacher. Among his pupils and followers were most of the significant Florentine painters of the first half of the 16th century—Rosso Fiorentino, Pontormo, Francesco Salviati, and Giorgio Vasari, for example—and it is largely through his example that the tradition of Florentine art was transmitted (but transformed) through to the end

"St. Thomas Aquinas Enthroned Between the Doctors of the Old and New Testaments, with Personifications of the Virtues, Sciences, and Liberal Arts," fresco by Andrea da Firenze, c. 1365; in the Spanish Chapel of the church of Sta. Maria Novella, Florence

SCALA—Art Resource/EB Inc

Andrea studied at the Arte dei Medici e degli Speziali in Florence. At the end of 1365 he was commissioned to decorate the chapter house of the church of Sta. Maria Novella. Also attributed to him are the decorations in the Spanish chapel and the cartoon (full-scale drawing) for the stained-glass window of the facade. Although he was acquainted with Giotto's innovations in modelling and spatial depth, he was strongly influenced by the linear, hieratic art of his Florentine contemporary Andrea Orcagna, and most of his works display the rigid compositions and immobile faces associated with the Byzantine tradition.

Also attributed to Andrea are the three upper panels of a mural showing the life of St. Ranieri in the Campo Santo (cemetery) at Pisa.

Andrea DEL GOBBO: see Solari, Andrea.

Andrea DEL SARTO, original name **ANDREA D'AGNOLO** (b. July 16, 1486, Florence—d. Sept. 28, 1530, Florence), Italian painter and draftsman whose works of exquisite composition and craftsmanship were instrumental in the development of the Florentine-Roman school in the first half of the 16th century. His most striking among other well-known works is the series of frescoes on the life of St. John the Baptist about 1511 and completed in 1526.

Life. Sarto's family name was probably Lanfranchi, and his father was a tailor (hence "del Sarto"; Italian *sarto*, "tailor"). Little of real interest is known about his life, probably because it was for the most part uneventful. He was notably short in stature and known to

times commissions of a major sculptor, Jacopo Sansovino, which led him to an increasingly and, in the end, exceptionally solidly structured style. These were the years in which Il Rosso and Pontormo were his pupils, and it may fairly be said that around 1513–14 the leadership in Florentine painting passed from Fra Bartolommeo's workshop to his.

In 1517 or 1518 Sarto married Lucrezia del Fede, a widow whom he had, according to her testimony, used as a model for several years; she brought him property and a useful dowry. In 1518 he was summoned by the king of France, Francis I, to Fontainebleau, where he was preceded by a reputation based upon pictures made for export. It is unlikely that he found the life of a court artist congenial, and he remained for a year or less without beginning any major commission. Soon after his return, his connections with the Medici family (powerful since their return to Florence from exile in 1512) led to the most significant contract of his career—for part of the decoration of the Villa Medici at Poggio a Caiano, near Florence. The patron was in fact the pope, Leo X, whom Sarto almost certainly visited in Rome in 1519–20; but the project, the only one that ever offered Florentine artists the scope that Raphael had in the Vatican Palace, collapsed when the Pope died in December 1521. Sarto's fresco "Tribute to Caesar" is a fragment now incorporated into a much later scheme of decoration.

In 1520 Sarto began to build himself a house in Florence, which was later inhabited and modified by several other painters; it was a substantial property without being a palace.

of the Renaissance and was able to embrace the stylistic innovations made around 1500 by Leonardo da Vinci and Michelangelo.

The suspicion that, while he was worthy and sound, Sarto nevertheless lacked some essential creative fire can be traced back to malicious accounts written by Giorgio Vasari, a 16th-century biographer and artist for whom

"Marriage of St. Catherine," oil on panel by Andrea del Sarto, 1512–13; in the Gemäldegalerie Alte Meister, Dresden, Ger.

Sächsische Landesbibliothek/Abteilung Deutsche Fotothek/A. Rous

Sarto was a disgrace to the profession. Vasari's specific complaint was that Sarto lacked ambition, and in Vasari's terms the complaint was probably true, for the opportunities for worldly success that Raphael enjoyed could have been his, too, but he did not take them.

(J.K.Sh.)

BIBLIOGRAPHY. Sydney J. Freedberg, *Andrea del Sarto*, 2 vol. (1963); and John Shearman, *Andrea del Sarto*, 2 vol. (1965), are well-illustrated monographs containing references to earlier writings; the selected bibliography in the former is especially useful. Each contains a catalogue raisonné of paintings; the second has in addition a separate catalog of drawings and register of documents. There are significant differences of opinion as to attributions, chronology, and general assessment.

Andrea DEL VERROCCHIO (sculptor): see Verrocchio, Andrea del.

Andrea DI CIONE (c. 1308–c. 1368): see Orcagna, Andrea.

Andrea PISANO (Italian sculptor): see Pisano, Andrea.

Andreani, Andrea (fl. c. 1580–c. 1625, Italy), Italian printmaker known especially for his chiaroscuro printing, a technique developed in the early 16th century to facilitate shading. In this technique, several wood blocks are used for the same print, each block engraved to produce a different tone of the same colour.

Andreani was active in Florence (1584–85), in Siena (1586–93), and in Mantua (1599). Between 1602 and 1610 he appears in contemporary documents as a publisher of prints that were not of his own design. All of Andreani's known woodcuts, in fact, are after the paintings of other artists, especially the 15th-century Mannerists Giambologna and Domenico Beccafumi, and the Venetian early Baroque painter Jacopo Ligozzi. The best known of Andreani's works are 12 large woodcuts representing the "Trionfo di Giulio

Cesare" ("Triumph of Julius Caesar") and a series of prints reproducing nine sequential canvases by Andrea Mantegna. The several sections of this work were intended to be pasted together or mounted as a single frieze; each print has an individual character yet fits into its place in the unified whole.

Andreanof Islands, group of the Aleutian Islands, southwestern Alaska, U.S. They lie between the Pacific Ocean (south) and the Bering Sea (north) and extend east-west for about 270 miles (430 km) between the Fox and Rat island groups. The Andreanof Islands were strategically important in World War II, and there is a U.S. military installation on Shemya Island.

Andreas CAPELLANUS (12th century): see André le Chapelain.

Andreas-Salomé, Lou (b. Feb. 12, 1861, St. Petersburg, Russia—d. Feb. 5, 1937, Göttingen, Ger.), Russian-German writer remembered for her friendships with the great men of her day.

Salomé was the daughter of a Russian army officer of French Huguenot descent. She studied theology at the University of Zürich. In 1882 the German philosopher Friedrich Nietzsche fell in love with her, but she rejected his proposal of marriage. In 1887 she married the Orientalist Friedrich C. Andreas, a professor at the University of Göttingen. In 1897 she met the poet Rainer Maria Rilke, who was 14 years younger than she and who also fell in love with her; she became one of the formative influences on his life. In 1911 she became associated with the Vienna circle of psychoanalysts and was a friend and disciple of Sigmund Freud.

Besides novels, her works include *Friedrich Nietzsche in seinen Werken* (1894; "Friedrich Nietzsche in His Works"), *Rainer Maria Rilke* (1928), and *Mein Dank an Freud* (1931; "My Thanks to Freud"). Her correspondence with Rilke was published in 1952.

Andreev, Leonid Nikolayevich (Russian novelist): see Andreyev, Leonid Nikolayevich.

Andreini, Francesco (b. 1548, Pistoia [Italy]—d. Aug. 20, 1624, Mantua), actor of commedia dell'arte who, with his wife, Isabella (see Andreini, Isabella), was a founder and star performer of the Compagnia dei Gelosi, one of the earliest and most famous of commedia dell'arte troupes.

Andreini began his career as a soldier but was captured by the Turks and held in slavery by them for several years. Upon his return to Italy, he joined the company of the producer-director Flaminio Scala, playing lovers. He is identified with the character of Capitano Spavento, the braggart Spanish soldier, and in 1607 published descriptions of that role, including dialogue and stage business, as *Le bravure del Capitano Spavento* ("The Bravery of Captain Spavento"). The Gelosi troupe visited the French court intermittently and traveled all over Europe. Isabella's death in 1604 led to Andreini's retirement from the stage and to the dissolution of the Gelosi.

Andreini, Giovambattista (b. Feb. 9, 1579?, Florence [Italy]—d. June 7/8, 1654, Reggio nell'Emilia, Sicily), actor of commedia dell'arte and son of Francesco and Isabella Andreini. Giovambattista was also the author of the play *Adamo* ("Adam"), which, it has been claimed, suggested the idea of *Paradise Lost* to John Milton.

Andreini began his stage career with the Compagnia dei Gelosi founded by his parents, but about 1601 he formed his own troupe, the Compagnia dei Fedeli, and toured Italy until 1613, when the company was invited to Paris by Marie de Médicis, to whom he dedicated his play *Adamo* (1613). In 1618 he returned to Italy for three years, then traveled back to Paris in 1621, again at the invitation

of Marie, where he played at the Hôtel de Bourgogne until 1624 and again in 1625. He acted throughout Europe nearly until he died. His writings include several ecclesiastical dramas, some religious poems, and a number of comedies.

Andreini, Isabella, née ISABELLA CANALI (b. 1562, Padua, republic of Venice [Italy]—d. July 10, 1604, Lyon, France), celebrated leading lady of the Compagnia dei Gelosi, most famous of the early commedia dell'arte companies.

In 1578 Flaminio Scala, a theatrical manager and scenario writer, engaged Isabella Canali to play the female lead in his company. There she met Francesco Andreini and married him the same year. They helped form the Gelosi troupe, with which she toured Italy and France until her death. A brilliant and beautiful woman, she was the subject of adoring verse by both French and Italian poets. At a Roman festival, given by her admirer Cardinal Cinzio Aldobrandini, her portrait was hung, crowned with laurels, between those of Torquato Tasso and Plutarch. Isabella was herself a minor poet and author of a pastoral play, *Mirilla*. A book of songs, sonnets, letters, and other verse was published after her death by her husband and Scala. Her death prompted her husband's retirement from the stage and was the inspiration of numerous elegies. Her son Giovambattista was a commedia dell'arte actor and a prolific author.

Andreis, Felix de, in full ANDREW JAMES FELIX BARTHOLOMEW DE ANDREIS (b. Dec. 13, 1778, Demonte, Piedmont [Italy]—d. Oct. 15, 1820, St. Louis, Missouri territory [U.S.]), Vincentian priest and pioneer missionary to the American West.

Ordained at Piacenza (Italy) in 1802, Andreis was transferred (1806) to Rome, where he served as preacher, professor of theology, and apostle to the poor. While on a visit to Rome in 1815, William Du Bourg, the bishop of Louisiana, arranged for Andreis to serve his diocese. Andreis was appointed temporary vicar-general and superior of a band of missionaries who embarked for the American missions. After a long delay at the Seminary of St. Thomas in Kentucky, where he taught theology, Andreis arrived in St. Louis in 1817 and was appointed vicar-general. He was professor and administrator of two colleges, one for seminarians and one for laymen, and supervised the erection of a novitiate at the Barrens, 80 miles (130 km) south of St. Louis. During his lifetime he gained a reputation for sanctity, and several miracles were attributed to his intercession after his death.

Andreotti, Giulio (b. Jan. 14, 1919, Rome, Italy), Christian Democratic politician who was several times prime minister of Italy in the period from 1972 to 1992. He was one of Italy's most skillful and powerful politicians in the era after World War II.

Andreotti, 1978

UPI/Bettmann

Andreotti took a degree in law at the University of Rome and was president of the Catholic students' federation. In 1942 he became a protégé of Alcide De Gasperi, who would soon

organize the Christian Democratic Party. In 1946 Andreotti was elected to the Constituent Assembly that drafted Italy's new constitution, and in 1947 he was elected to the Chamber of Deputies, to which he was reelected regularly thereafter. That same year he was appointed undersecretary to Prime Minister De Gasperi's cabinet, and he retained that post until 1953. His first cabinet post was as interior minister in Amintore Fanfani's government in 1954. Andreotti subsequently served as minister of finance (1955–58), treasury (1958–59), defense (1959–66), and industry and commerce (1966–68).

Andreotti's first prime ministry lasted only four months in 1972. Soon afterward he formed his second government, a coalition that lasted until June 1973. His third ministry, formed in 1976, comprised only Christian Democrats but held power with the tacit support of the Italian Communist Party until 1979. This tactical alliance enabled Andreotti to undertake the harsh austerity measures needed to deal with Italy's mounting economic problems. Andreotti then served as minister of foreign affairs from 1983 to 1989 in various coalition governments. He again served as prime minister in a coalition from 1989 to April 1992, when he stepped down after the Christian Democrats had suffered a serious setback in general elections that year.

Andreotti was long active in journalism and was a cofounder of his party's daily newspaper, *Il Popolo*. He was the author of *De Gasperi e il suo tempo* (1956; "De Gasperi and His Time") and other books. The collapse of the Christian Democratic Party in the mid-1990s left Andreotti vulnerable to prosecution on various charges of corruption. In 1995 he was indicted for selling political favours to the Mafia and for complicity in the murder of a journalist in 1979. The dramatic trial relating to the Mafia charges lasted for more than three years and ended in his 1999 acquittal. In 2002, however, Andreotti was found guilty of murder and sentenced to 24 years in prison. That conviction was overturned in 2003 by Italy's highest court.

Andretti, Mario, in full MARIO GABRIEL ANDRETTI (b. Feb. 28, 1940, Montona, Italy), automobile racing driver who drove stock cars, U.S. championship cars, and Formula I cars.

Mario and his twin brother Aldo studied automobile mechanics, frequented racing-car garages, and participated in a race-driving training program in Italy. In 1955 the family came to the United States and settled in Nazareth, Pa.; Mario became a U.S. citizen in 1964. By 1958 the brothers were racing stock cars. Aldo was severely injured in an accident and gave up racing in 1969. In the early 1960s Mario drove sprint and midget cars in races and in 1964 began racing in the championship-car division of the United States Automobile Club (USAC). He won USAC championships (1965–66, 1969). He also won the Daytona Beach (Fla.) 500-mile stock-car race (1967) and the sports-car Grand Prix of Endurance race at Sebring, Fla. (1967, 1970).

Andretti won the Indianapolis 500 race in 1969. An apparent victory in the 1981 race was ultimately given to Bobby Unser. (Andretti was penalized for passing cars during a yellow flag.) He was the second American driver to win the Formula I world championship in 1978. (Phil Hill was the first in 1961.) He retired from competition in 1994.

Andrew I, Russian in full ANDREY YURYEVICH BOGOLYUBSKY (b. c. 1111—d. June 1174, Bogolyubovo, near Vladimir, Russia), prince of Rostov-Suzdal (1157) and grand prince of Vladimir (1169), who increased the importance of northeastern Rus (present-day northwestern Russia) and contributed to the development of government in that forest region.

Having accompanied his father, Yuri Dolgo-

rky, on his conquest of Kiev, Andrew refused to remain in the ancient capital of Rus and returned to Vladimir, a town in his father's principality of Rostov-Suzdal in northeastern Rus. When his father died (1157), the cities of Rostov and Suzdal elected Andrew their prince, and he transferred the capital of the entire principality to Vladimir. Subsequently, he encouraged colonists to settle in his principality, fortified and enlarged Vladimir, and built many churches.

In addition to strengthening his own lands, Andrew strove to extend his authority over other principalities of Rus. In 1169 he and his allies sacked Kiev, and Andrew acquired the title grand prince. But rather than move his seat to Kiev, as his father had done, Andrew made Vladimir the centre of the grand principality and placed a series of his relatives on the now secondary princely throne of Kiev. Later he also compelled Novgorod to accept a prince of his choice. In governing his realm, Andrew not only demanded that the subordinate princes obey him but also tried to reduce the traditional political powers of the boyars (*i.e.*, the upper nobility) within his hereditary lands. In response, his embittered courtiers formed a conspiracy and killed him.

Andrew II, Hungarian ENDRE, or ANDRAS (b. 1175—d. Oct. 26, 1235), king of Hungary (1205–35) whose reign was marked by controversy with barons and the great feudatories and by the issuance of the Golden Bull of 1222 (*q.v.*), which has been called the Hungarian Magna Carta.

The son of Béla III, Andrew succeeded László III, his elder brother's son, on the throne in 1205. Powerful landed interests forced Andrew to spend royal funds so recklessly that the crown was soon impoverished and dependent on the feudatories, who soon reduced Hungary to a state of near anarchy. Objecting to the prodigality of the German followers of Andrew's first wife, Gertrude of Meran, rebellious nobles murdered her in 1213. Four years later, with an army of 15,000 men, Andrew set off on an ill-fated Crusade to the Holy Land. After his return the barons forced him to agree to the Golden Bull, which became an important source of the Hungarian constitution. It limited royal rights and prerogatives, confirmed basic rights of smallholders and nobles, guaranteed justice for all, and promised to improve the coinage. Under it, nobles had the right to resist by force any royal decree. Andrew's daughter by Gertrude was canonized as St. Elizabeth of Hungary.

Andrew, SAINT (d. traditionally AD 60/70, Patras, Achaia [Greece]; feast day November 30), one of the Twelve Apostles and brother of St. Peter. He is the patron saint of Scotland and of Russia.

In the Synoptic Gospels (Matthew, Mark, and Luke), Peter and Andrew—whose Greek name means "Manly"—were called from their fishing by Jesus to follow him, promising that he would make them fishers of men. With Saints Peter, James, and John, Andrew asked Jesus on the Mount of Olives for signs of the earth's end, which inspired the eschatological discourse in Mark 13. In John's Gospel he is the first Apostle named, and he was a disciple of St. John the Baptist before Jesus' call.

Early Byzantine tradition (dependent on John 1:40) calls Andrew *protokletos*, "first called." Early church legends recount his missionary activity in the area about the Black Sea. Apocryphal writings centred on him include the *Acts of Andrew*, *Acts of Andrew and Matthias*, and *Acts of Peter and Andrew*. A 4th-century account reports his death by crucifixion, and late medieval accretions describe the cross as X-shaped. He is iconographically represented with an X-shaped cross (like that depicted on the Scottish flag).

St. Jerome records that Andrew's relics were taken from Patras (modern Pátrai) to Con-

stantinople (modern Istanbul) by command of the Roman emperor Constantius II in 357. In 1208 the body was taken to Amalfi, Italy (Church of Sant' Andrea), and in the 15th century the head was taken to Rome (St. Peter's, Vatican City). In September 1964 Pope Paul VI returned Andrew's head to Pátrai.

Andrew OF CAESAREA (fl. 6th–7th century), bishop of Caesarea, and the author of possibly the most significant Greek commentary on the book of Revelation (Apocalypse) from the era of the Church Fathers. His annotations seem to have influenced the Greek version of that biblical text.

Andrew's exposition of the book of Revelation is marked by a specific Christian interpretation of history which views that biblical text as expressing the actual divine government of the world. He asserted that the biblical text's figurative and symbolic senses are not to be taken as simply imaginative. Rather, these "mystical" forms are to be seen as expressions of realities and experiences that transcend the capacity of human language. In his glosses on the book of Revelation, Andrew often presents the interpretations of various early Christian writers. These and quotations from his own writings often provide the only surviving fragments of the works cited.

Critical scholarship has suggested that Andrew's glosses frequently became part of the book of Revelation's text, resulting in some of its enigmatic passages. Andrew's commentary, in more than 70 manuscripts that have been used as sources by subsequent commentators, is contained in the series by J.P. Migne (ed.), *Patrologia Graeca*, vol. 106 (1866).

Andrew OF CARNIOLA, also called ANDREW OF KRAINA (d. Nov. 13, 1484, Basel, Switz.), archbishop, advocate of conciliar rule in the Western church—*i.e.*, the supremacy of a general council of bishops over the papacy. Because of his personal animosity and eccentric conduct toward Pope Sixtus IV, church historians generally do not consider Andrew a precursor of reform.

From the scant data available on Andrew's life, it appears that he was of Slavic origin and a member of the quasi-monastic Dominicans at the order's convent in Udine (Italy). Supported by the Holy Roman emperor Frederick III, he was named archbishop of Carniola in January 1476, while continuing to live elsewhere. He arrived in Rome about 1478 to represent Emperor Frederick at the court of Pope Sixtus IV. After an unsuccessful attempt to be named a cardinal of the church, he denounced the pope and was imprisoned. Freed by Frederick's intervention, Andrew traveled to Florence and Milan, seeking support from Sixtus' foes. Arriving at Basel, he announced a general council, principally to depose Sixtus, and nailed a formal indictment of the pope to the doors of the cathedral. This action apparently was an appeal to reconvene the Council of Basel (1431–37), which had vainly attempted to subject the pope to its authority by decreeing that the assembly of bishops governed directly by divine right.

Lacking the support of the bishops, Andrew met with antipapal agents from Florence and Milan to devise strategy. In September 1482 Pope Sixtus placed Basel under interdict (prohibiting the clergy to exercise any sacramental ministry) for extending protection to Andrew. Papal ambassadors then obtained from Frederick a decree placing Andrew in the custody of Basel's governing council, but he later was consigned to papal authorities. Condemned to life imprisonment in Basel, Andrew is said to have hanged himself in his cell.

Andrew OF CRETE, SAINT (b. c. 660, Damascus, Syria—d. July 4, 740; feast day July

4), archbishop of Gortyna, Crete, regarded by the Greek Church as one of its greatest hymn writers.

From his monastery in Jerusalem he was sent to Constantinople (modern Istanbul), where he became deacon of the Hagia Sophia. During the reign of the Byzantine emperor Philipppicus Bardanes he was made archbishop of Gortyna and took part in the Synod of Constantinople (712), where he subscribed to Monothelitism (see Monothelites). He recanted his Monothelitic views in 713.

In developing the Byzantine liturgy, he is credited with inventing the canon, a new genre of hymnography that consists of nine odes in stanzaic form, each sung to a different melody. His canon replaced the kontakion, a homiletic hymn of which all stanzas were sung to the same melody. Andrew was the author of many hymns and canons still used in Greek liturgical books.

Andrew OF LONJUMEL, Lonjumel also spelled LONGJUMEAU, or LONGUMEAU (fl. 1238–53), French Dominican friar who, as an ambassador of Louis IX (St. Louis) of France, led a diplomatic mission destined for the court of the Mongol khan Güyük. His report of the journey across Central Asia and back (1249 to 1251/52), though a mixture of fact and fiction, contains noteworthy observations.

On his first diplomatic mission, to Constantinople (1238), he brought back the relic revered as Christ's crown of thorns, for which Louis built Sainte-Chapelle at Paris as a repository. In 1247 he accompanied a mission sent by Pope Innocent IV to the Mongols at Kars, Armenia (now in Turkey), and returned to Louis with a Mongol proposal for a joint attack upon Islâm for the conquest of Syria. Louis then sent Andrew on a diplomatic mission to Güyük to continue negotiations. Departing from Cyprus with several companions early in 1249, he travelled around the southern and eastern shores of the Caspian Sea and, continuing through Turkistan north of Tashkent, went on to Karakorum in central Mongolia. Upon reaching the court, Andrew found that Güyük was dead, and was sent back to Louis with an insolent letter from the regent mother, Ogul-Gaimish. Andrew's account of the journey, though known only from references in the travel writings of the Franciscan friar William of Rubruquis, describes Tatar customs with fair accuracy.

Andrew OF WYNTOUN: see Wyntoun, Andrew of.

Andrew, John Albion (b. May 31, 1818, Windham, Maine, U.S.—d. Oct. 30, 1867, Boston), U.S. antislavery leader who, as governor of Massachusetts during the Civil War, was one of the most energetic of the Northern "war governors."

Andrew entered political life as a Whig opposed to the Mexican War (1846–48). In 1848

John Albion Andrew, photograph by Mathew Brady

he joined the Free-Soil movement against the spread of slavery. After the passage of the Kansas-Nebraska Act (1854), which permitted those territories to choose between slavery and freedom, he helped organize the Republican Party in Massachusetts. In 1859 he defended the abolitionist John Brown so vigorously that he was summoned to Washington to appear before an investigating committee of the Senate. In 1860 he led the Massachusetts delegation at the Republican convention at Chicago, which nominated Lincoln for the presidency; from 1861 to January 1866 he was governor of Massachusetts.

Andrewes, Lancelot (b. 1555, London—d. Sept. 26, 1626, London), theologian and court preacher who sought to defend and advance Anglican doctrines during a period of great strife in the English church.

Lancelot Andrewes, detail of an oil painting by an unknown artist

Andrewes was elected a fellow of Pembroke College, Cambridge, in 1575 and was ordained a deacon in 1580. His service to several parishes from 1589 was followed by consecration as bishop of Chichester in 1605 and his transfer to Ely in 1609 and to Winchester in 1619; he had earlier refused the sees of Salisbury and Ely because Elizabeth I had insisted that he cooperate with the crown in reducing the power of the church. Under James I and Charles I he was lord almoner (1605–19) and dean of the chapels royal (1619–26). A master of rhetoric, he earned a reputation as an eloquent and learned court preacher.

Despite his exposure to Puritan influence at Cambridge, Andrewes was a critic, consistent, if cautious, of both Calvinist dogmas and Puritan reform platforms. His major writings, however, were apologetic works directed against the Roman Church, in which he combined a critique of distinctly Roman Catholic dogmas with a positive statement of Anglican teachings.

Among his sermons are those he preached on several successive anniversaries of the thwarted Gunpowder Plot of 1605, in which an attempt was made to blow up Parliament and the royal family by Catholics angry over anti-Catholic legislation; the sermons stress the deliverance by God of both the nation and the church. A bibliography of his sermons and other writings is included in the biography by P.A. Welsby, *Lancelot Andrewes, 1555–1626* (1958).

Andrews, Augustus George (English actor): see Arliss, George.

Andrews, Charles McLean (b. Feb. 22, 1863, Wethersfield, Conn., U.S.—d. Sept. 9, 1943, New Haven, Conn.), U.S. teacher and historian whose *Colonial Period of American History*, vol. 1 of 4, won him a Pulitzer Prize in 1935.

After teaching at various American universities, Andrews was professor of American history at Yale University from 1910 to 1931. Well started on his important guides to colonial materials in English archives before he went to Yale, he became a leader in colonial

historiography. His own history belongs to the "imperial school," which places the emphasis on the American colonies as dependent parts of the British system so that the centre of the colonial story belongs in Great Britain. This interpretation runs through his widely accepted books and those of historians he trained.

Among his writings are *Colonial Self-Government, 1652–89*, vol. 5 of *The American Nation, a History* (1904), and *The Colonial Period* (1912).

Andrews, Frank M(axwell) (b. Feb. 3, 1884, Nashville, Tenn., U.S.—d. May 3, 1943, Iceland), U.S. soldier and air force officer who contributed signally to the evolution of U.S. bombardment aviation during his command (1935–39) of the General Headquarters Air Force, first U.S. independent air striking force.

Graduating from the U.S. Military Academy at West Point, N.Y., in 1906, Andrews was commissioned in the cavalry, serving in the Philippines and Hawaii, but in 1917 he transferred to the new air service, rising to lieutenant colonel by the end of World War I. After holding a number of routine service assignments, he was named commander of the newly created General Headquarters Air Force in 1935.

A determined though moderate advocate of strategic air power, Andrews is credited with development of the Boeing B-17 bomber; his command became the model for the powerful army air forces of World War II. During the war Andrews, as air commander in the Caribbean and later as head of the Caribbean defense command, was the first U.S. airman to command an entire theatre. He was promoted to lieutenant general in 1941. In February 1943, three months before his death in an air crash, he assumed command of all U.S. forces in Europe, succeeding Gen. Dwight D. Eisenhower when the latter was named Allied

Commander of the North African theatre of operations.

Andrews, Roy Chapman (b. Jan. 26, 1884, Beloit, Wis., U.S.—d. March 11, 1960, Carmel, Calif.), naturalist, explorer, and author, who led many important scientific expeditions for which he obtained financial support through his public lectures and books, particularly on central Asia and eastern Asia.

After graduating from Beloit (Wis.) College in 1906, he took a position at the American Museum of Natural History in New York City. In 1908 he went on his first expedition, to Alaska, and on that trip and until 1914 he specialized in the study of whales and other aquatic mammals; through his efforts the museum's collection of cetaceans became one of the best in the world. In 1909–10 he was a naturalist on the USS "Albatross" on its voyage to the Dutch East Indies; in 1911–12 he explored northern Korea and in 1913 participated in the Borden Alaska expedition.

While serving as chief of the division of Asiatic exploration of the American Museum of Natural History, he led three expeditions, to

Roy Chapman Andrews

By courtesy of the American Museum of Natural History, New York

Tibet, southwest China, and Burma (1916–17); northern China and Outer Mongolia (1919); and central Asia (1921–22 and 1925). Numerous important discoveries were made on the third Asian expedition: the first known dinosaur eggs; a skull and other parts of *Baluchitherium*, the largest known land mammal; extensive deposits of fossil mammals and reptiles previously unknown; evidence of prehistoric human life; and geological strata previously unexplored in that region.

Andrews was the director of the American Museum of Natural History from 1935 to 1942, when he resigned in order to write. His books include *Whale Hunting with Gun and Camera* (1916), *Camps and Trails in China* (1918), *Across Mongolian Plains* (1921; with Yvette Borup Andrews), *On the Trail of Ancient Man* (1926), *Ends of the Earth* (1929), *The New Conquest of Central Asia* (1933), *This Business of Exploring* (1935), *This Amazing Planet* (1940), the autobiographical *Under a Lucky Star* (1943) and *An Explorer Comes Home* (1947), and *Beyond Adventure* (1954).

Andrews, Thomas (b. Dec. 19, 1813, Belfast, Ire.—d. Nov. 26, 1885, Belfast), chemist and physicist who established the concepts of critical temperature and pressure and showed that a gas will pass into the liquid state, and vice versa, without any discontinuity, or abrupt change in physical properties. He also proved that ozone is a form of oxygen.

Following studies in Britain and Paris, he received a medical degree from the University of Edinburgh (1835). He was appointed vice president of Northern College in Belfast in 1845 and helped to prepare it for its reorganization as Queen's College, Belfast (1849). He was professor of chemistry there from 1849 to 1879.

Andrey (Russian personal name): see under Andrew.

Andreyev, Leonid Nikolayevich, Andreyev also spelled ANDREEV (b. Aug. 21 [Aug. 9, old style], 1871, Oryol, Russia—d. Sept. 12, 1919, Kuokkala, Fin.), novelist whose best work has a place in Russian literature for its evocation of a mood of despair and absolute pessimism.

At the age of 20 Andreyev entered St. Petersburg University but lived restlessly for some time. In 1894, after several attempts at suicide, he transferred to the University of Moscow, where he studied law. He became a barrister and then a law and crime reporter, publishing his first stories in newspapers and periodicals. Encouraged by Maksim Gorky, who became a close friend, he was at first regarded as Gorky's successor as a Realist. His "Zhili-byli" ("Once There Lived . . .") attracted attention and was included in his first collection of short stories (1901). Two stories of 1902, *Bezдна* ("The Abyss") and *V tumane* ("In the Fog"), caused a storm by their candid and audacious treatment of sex. Andreyev's work became widely discussed, and he acquired fame and wealth with a series of novels and short stories that, at their best, resemble Tolstoy in their powerful themes and ironic sympathy for suffering humanity. Among his best tales are *Gubernator* (1905; *His Excellency the Governor*, 1921)

and *Rasskaz o semi poveshennykh* (1908; *The Seven That Were Hanged*, 1909).

Andreyev's fame as a novelist declined rapidly as his works became increasingly bizarre and sensational. He began a career as a dramatist in 1905. His most successful plays—*Zhizn cheloveka* (1907; *The Life of Man*, 1915) and *Tot, kto poluchayet poshchyochiny* (1916; *He Who Gets Slapped*, 1921)—were allegorical dramas, but he also attempted Realist comedy.

During World War I, Andreyev became editor of a government-inspired newspaper, and his writing became predominantly patriotic. A fervent antirevolutionary, he moved to Finland after the Bolsheviks came to power; his last work, *S.O.S.* (1919), was an appeal to the Allies to save Russia.

Andria, city, Bari province, Puglia (Apulia) region, southeastern Italy, on the eastern slopes of the Murge plateau, just south of Barletta. Andria was perhaps the Netium mentioned by the 1st-century BC Greek geographer Strabo, but its recorded history began with the arrival of the Normans in the 11th century AD, when Pietro I, Norman count of nearby Trani, enlarged and fortified the minor

Castel del Monte, near Andria, Italy

Bohnacker—L. Palnic

settlement of Locum Andre. It later became a favourite hunting residence of the emperor Frederick II, who in 1240 built the Castel del Monte (11 mi [17 km] south), a massive octagonal Gothic structure. Eventually the city passed to the Angevin dynasty, Otto IV (Otto of Brunswick), and the Orsini, Acquaviva, and Carafa families. The city has some Roman remains, and the restored 10th-century cathedral contains the tombs of Isabella (Yolande) of Brienne and Isabella of England, the second and third wives of Frederick II. There are several other notable churches and palaces.

Andria is on the railway from Bari to Foggia. Agriculture, especially the cultivation of vines, olives, and almonds, is the chief industry; there is also wine production, oil refining, and the manufacture of textiles. Pop. (1990 est.) mun., 89,762.

Andrić, Ivo (b. Oct. 10, 1892, Dolac, near Travnik, Bosnia—d. March 13, 1975, Belgrade, Yugos.), writer of Serbo-Croatian nov-

Andrić, 1961

els and short stories who was awarded the Nobel Prize for Literature in 1961.

Andrić studied at Zagreb, Kraków, Vienna, and Graz. His potentialities as a writer of both prose and verse were recognized early, and his reputation was established with *Ex Ponto* (1918), a contemplative, lyrical prose work written during his internment by Austro-Hungarian authorities for nationalistic political activities during World War I. Collections of his short stories were published at intervals from 1920 onward.

Following World War I, he entered the Yugoslavian diplomatic service. Although his career took him to Rome, Bucharest, Madrid, Geneva, and Berlin, it was his native province, with its wealth of ethnic types, that provided the themes and psychological studies to be found in his works. Of his three novels, written during the second World War, two—*Travnička hronika* (1945; *Bosnian Story*, 1959) and *Na Drini ćuprija* (1945; *The Bridge on the Drina*, 1959)—are concerned with the history of Bosnia.

Andrić's works reveal his deterministic philosophy and his sense of compassion and are written objectively and soberly, in language of great beauty and purity. The Nobel Prize committee commented particularly on the "epic force" with which he handled his material, especially in *The Bridge on the Drina*.

Androcles, also spelled ANDROCLUS, Roman slave who allegedly lived about the time of the emperor Tiberius or Caligula and who became the hero of a story by Aulus Gellius. The story, taken originally from Apion's *Aiguptiaka* and also found in Aelian's *De natura animalium*, tells that Androcles had taken refuge from the cruelties of his master in a cave in Africa, when a lion entered the cave and showed him his swollen paw, from which Androcles extracted a large thorn. Later, the grateful animal recognized him when Androcles had been captured and thrown to the wild beasts in the circus and, instead of attacking him, began to caress him; he was then set free. The story is the subject of the play *Androcles and the Lion* by George Bernard Shaw.

androgen, any of a group of hormones that primarily influence the growth and development of the male reproductive system.

Production. The predominant and most active androgen is testosterone (*q.v.*), which is produced by the male testes. The other androgens, which support the functions of testosterone, are produced mainly by the adrenal cortex—the outer substance of the adrenal glands—and only in relatively small quantities. Trace quantities of androgens are found in the female blood plasma. It is believed that the adrenal glands produce most of these small amounts. The ovaries, which normally secrete the female hormones known as estrogens, also produce minute amounts of androgens.

In the male, the interstitial cells of Leydig, located in the connective tissue surrounding the sperm-producing tubules of the testes, are responsible for the production and secretion of androgens. In male animals that breed only seasonally, such as migratory birds and sheep, Leydig cells are prevalent in the testes during the breeding season but diminish considerably in number during the nonbreeding season. The actual secretion of androgens by these cells is controlled by luteinizing hormone (LH) from the pituitary gland.

Effects. Androgens are needed for the development of the male reproductive system. Without injections of testosterone, males that have been castrated prior to adolescence and sexual maturity do not develop functioning adult reproductive organs. Androgens given to normal males tend to increase the size of

the reproductive organs; castration performed on males that have already reached maturity causes the organs to shrink and to stop functioning. Androgens are also necessary for the formation of sperm cells and for the maintenance of sexual interest and behaviour.

Other effects of androgens upon the male body are diversified. The growth of pubic hair and of facial and chest hair and the regression of scalp hair, or baldness, are influenced by androgens. During adolescence, androgens lengthen and thicken the male vocal cords, causing voice deepening; they also enhance bone growth and increase the number and thickness of muscle fibres in the male body. Other growth patterns that androgens stimulate are kidney weight and size, the increase of protein in bone tissue, the regeneration of red blood cells, the presence of pigments in the skin, and the increased activity of sweat and sebaceous (oil-producing) glands.

Andromache, in Greek legend, the daughter of Eëtion (prince of Thebe in Mysia) and wife of Hector (son of King Priam of Troy). All her relations perished in or shortly after the taking of Troy by the Greek warrior Neoptolemus (Pyrrhus). When the captives were allotted, Andromache fell to Neoptolemus, the son of Achilles, whom she accompanied to Epirus and to whom she bore three sons. Neoptolemus was slain at Delphi, and he left Andromache and the kingdom as well to Helenus, the brother of Hector. After the death of Helenus, Andromache returned to Asia Minor with her youngest son, Pergamus, who there founded a town named after himself.

Andromeda, in Greek mythology, beautiful daughter of King Cepheus and Queen Cassiope of Joppa in Palestine (called Ethiopia) and wife of Perseus. Cassiope offended the Nereids by boasting that Andromeda was more beautiful than they, so in revenge Poseidon sent a sea monster to devastate Cepheus' kingdom. Since only Andromeda's sacrifice would appease the gods, she was chained to a rock and left to be devoured by the monster. Perseus flew by on the winged horse Pegasus, fell in love with Andromeda, and asked Cepheus for her hand. Cepheus agreed, and Perseus slew the monster. At their marriage feast, however, Andromeda's uncle, Phineus, to whom she had originally been promised, tried to claim her. Perseus turned him to stone with Medusa's head. Andromeda bore Perseus six sons and a daughter.

Andromeda, in astronomy, constellation of the northern sky at about one hour right ascension (the coordinate on the celestial sphere analogous to longitude on the Earth) and 40° north declination (angular distance north of the celestial equator), named for Andromeda of Greek legend. Its most notable feature is the great Andromeda Galaxy.

Andromeda Galaxy, also called **ANDROMEDA NEBULA** (catalog numbers NGC 224 and M31), great spiral galaxy in the constellation Andromeda, the nearest external galaxy (except for the Magellanic Clouds, which are companions of the Milky Way Galaxy, in which the Earth is located). The Andromeda Galaxy is one of the few visible to the unaided eye, appearing as a milky blur. It is located about 2,000,000 light-years from the Earth; its diameter is approximately 200,000 light-years; and it shares various characteristics with the Milky Way system. It was mentioned as early as AD 964, in the *Book of the Fixed Stars*, by the Arab astronomer as-Sūfi, and rediscovered in 1612, shortly after the invention of the telescope, by the German astronomer Simon Marius, who said it resembled the light of a candle seen through a horn. For centuries astronomers regarded the Andromeda as a

Andromeda Galaxy (NGC 224, M31)
By courtesy of Hale Observatories

component of the Milky Way Galaxy—i.e., as a so-called spiral nebula much like other glowing masses of gas within the local galactic system (hence the misnomer Andromeda Nebula). Only in the 1920s did the American astronomer Edwin Powell Hubble determine conclusively that the Andromeda was in fact a separate galaxy beyond the Milky Way.

Andronicus, name of Byzantine emperors grouped below and indicated by the symbol ●.

● **Andronicus I COMNENUS** (b. 1118, Constantinople—d. Aug. 12, 1185, Constantinople), Byzantine emperor from 1183 to 1185, the last of the Comnenus dynasty, who attempted to reform the government but whose bitter opposition to Western Christianity precipitated a Norman invasion.

A cousin of the emperor Manuel I Comnenus (reigned 1143–80), Andronicus opposed the unpopular regency of the dowager empress

Andronicus I (left), effigy on a gold solidus, 1183–85; in the British Museum
Peter Clayton

Mary of Antioch after Manuel's death. In the spring of 1182 he raised an army and entered Constantinople posing as the protector of the young emperor Alexius II; one of the results of his seizure of power was a massacre of the Westerners living in the city, mostly Venetians and Genoese. Soon after, he contrived the death of the Dowager Empress. In September 1183 he was crowned coemperor to Alexius and two months later had him strangled. To legitimize his usurpation, the 65-year-old Andronicus married Alexius' 13-year-old widow.

Andronicus attempted to improve life in the provinces by reforming the decaying political system, prohibiting the sale of offices, punishing corrupt officials, and, above all, checking the power of the great feudal nobles and landowners whose privileges undermined the unity of the empire. He repudiated the pro-Western policy of Manuel I and asserted the independence of the Eastern Church, thus arousing the hostility of Western Christians.

In 1183 Béla III of Hungary, claiming to be the avenger of the Dowager Empress (a Westerner), invaded the empire and sacked several cities. Sicilian Normans led by William II in August 1185 marched through Greece, occupying Thessalonica, the second city of the empire. At the news of the approaching Normans, a revolt broke out in the capital, Isaac II Angelus was proclaimed emperor, and Andronicus was put to death by a street mob.

● **Andronicus II PALAEOLOGUS** (b. 1260, Constantinople—d. 1332, Constantinople), Byzantine emperor who was the son of Michael VIII Palaeologus. During Andronicus' reign (1282–1328) the Byzantine Empire declined to the status of a minor state, confined by the Ottoman Turks in Anatolia and the Serbs in the Balkans.

An intellectual and a theologian rather than a statesman or soldier, Andronicus weakened Byzantium by reducing its land forces to a few thousand cavalry and infantry and eliminating the navy altogether, relying solely on a Genoese mercenary fleet. His lack of military initiative enabled the Ottoman Turks to gain control of nearly all of Anatolia by 1300, and his employment of Catalan mercenaries in 1304 ended disastrously, because the Catalans proved more inclined to pillage Byzantine cities than to fight the Turks. In the war between the Italian city-states of Venice and Genoa, he unwisely took sides, favouring Genoa, and suffered the wrath of the greatly superior Venetian navy.

Internally, Andronicus' reign was marked by a steady disintegration of centralized authority and increasing economic difficulties, but he did sponsor a revival of Byzantine art and culture and championed the independence of the Eastern Orthodox Church. During his reign the great monastery complex at Mt. Athos in Greece enjoyed its golden age.

In 1328 Andronicus, after quarreling with his grandson Andronicus III and excluding him from the succession, was deposed by him and entered a monastery.

● **Andronicus III PALAEOLOGUS** (b. 1296, Constantinople—d. June 15, 1341, Constantinople), Byzantine emperor who sought to strengthen the empire during its final period of decline.

Andronicus was the grandson of the emperor Andronicus II Palaeologus, but his youthful excesses cost him the favour of his grandfather, and, after he accidentally caused the death of his brother in 1320, the Emperor excluded him from the succession. A civil war ensued, with the younger Andronicus enlisting the support of the powerful Byzantine nobility, particularly the wealthy John VI Cantacuzenus; in 1325 Andronicus compelled the old emperor to recognize him as coemperor, with control over the provinces of Thrace and Macedonia. In May 1328 he forced his grandfather to abdicate and enter a monastery, and Andronicus became sole ruler.

As emperor, Andronicus relied heavily on the guidance of Cantacuzenus, who encouraged reform of the law courts and initiated the rebuilding of the imperial navy, which had been neglected in the reign of Andronicus' predecessor. Cantacuzenus himself became emperor in 1347. Also under Andronicus, the orthodox monasteries took a more active role in both ecclesiastical and civil affairs. In foreign policy Andronicus was forced to recognize Serbian suzerainty over Macedonia (1334) and suffered losses to the Ottoman Turks in Anatolia; but he managed to regain the islands of Chios, Phocaea, and Lesbos from the Genoese with the aid of the rebuilt navy and reasserted imperial control over the separatist Greek states of Epirus and Thessaly.

● **Andronicus IV PALAEOLOGUS** (b. 1348?, Constantinople—d. June 28, 1385), Byzantine emperor from 1376 to 1379. Conspiring

against his father, John V Palaeologus, he was imprisoned and deprived of his rights to the succession. John's rivals, the Genoese, however, helped Andronicus to escape, and he entered Constantinople on Aug. 12, 1376, and took his father prisoner; he was crowned the following year (Oct. 18, 1377). In 1379, however, it was his father's turn to escape—with Venetian and Turkish aid—and be restored to the throne, on the condition that he recognize Andronicus as his rightful heir and swear allegiance as the vassal of the sultan. Andronicus predeceased his father, and his own son became emperor as John VII Palaeologus.

Andronicus of Rhodes, also called **ANDRONICUS RHODIUS** (fl. 1st century BC), Greek philosopher noted for his meticulous editing and commentary of Aristotle's works, which had passed from one generation to the next in such a way that the presumed quality of the original texts had been lost and much superfluous material added to many of the major treatises. Andronicus studied the original texts to sift out extraneous material and arranged them in an order that he thought reflected the workings of Aristotle's mind. After completing the editing, he wrote a treatise that covered four topics: a defense of his procedure, a biography of Aristotle, an exploration into the question of authenticity, and an examination of the Aristotelian system of thought.

Andropov, Yury Vladimirovich (b. June 15 [June 2, Old Style], 1914, Nagutskoye, Russia—d. Feb. 9, 1984, Moscow), head of the Soviet Union's KGB (State Security Committee) from 1967 to 1982 and his country's leader as general secretary of the Communist Party's Central Committee from November 1982 until his death 15 months later.

The son of a railway worker, Andropov was a telegraph operator, film projectionist, and boatman on the Volga River before attending a technical college and, later, Petrozavodsk University. He became an organizer for the Young Communist League (Komsomol) in the Yaroslavl region and joined the Communist Party in 1939. His superiors noticed his abilities, and he was made head of the Komsomol in the newly created Karelo-Finnish Autonomous Republic (1940–44).

The turning point in Andropov's career was his transfer to Moscow (1951), where he was assigned to the party's Secretariat staff, considered a training ground for promising young officials. As ambassador to Hungary (July 1954–March 1957), he played a major role in coordinating the Soviet invasion of that country. Andropov then returned to Moscow, rising rapidly through the Communist hierarchy and, in 1967, becoming head of the KGB. Andropov's policies as head of the KGB were repressive; his tenure was noted for its suppression of political dissidents.

Andropov was elected to the Politburo, and, as Soviet leader Leonid Brezhnev's health declined, Andropov began to position himself for succession, resigning his KGB post in 1982. Andropov was chosen by the Communist Party Central Committee to succeed Brezhnev as general secretary on November 12, scarcely two days after Brezhnev's death. He consolidated his power by becoming chairman of the Presidium of the Supreme Soviet (president) on June 16, 1983.

Ill health overtook him by August 1983, and thereafter he was never seen again in public. He accomplished little and was succeeded by a former rival, Konstantin Chernenko.

Andros, island, most northerly and second largest of the Cyclades group of Greek Aegean Islands. Andros has an area of 145 square miles (380 square km). Wooded, well-watered, and mountainous, it is an *eparkhiá* ("eparchy"), with its capital at the town of Ándros, on the east coast. South of the capital is the port of Kóρθιον, which lies at the foot of

the Palaiókastro (2,050 feet [625 m]), with ruins of a Venetian castle and medieval town. The ruins of Palacopolis, the island's ancient capital, support a hamlet, Palaiópolis, on the western coast. Figs, citrus fruits, wine grapes, and olives are grown on the island.

The ancient population was mainly Ionian. Originally dependent upon Eretria, Andros sent colonies to Chalcidice, the great peninsula of northeastern Greece, in the 7th century BC. It submitted to Persia in 490 BC and was harried by the Athenian fleet for supplying ships to the Persian king Xerxes in 480. The Athenian leader Pericles forced Andros to admit Athenian settlers, but it revolted in 411 or 410. During the 4th century BC it was again a member of the revived anti-Spartan Delian League. In 200 it was captured by a combined Roman, Pergamese, and Rhodian fleet. It remained with Pergamum until 133 BC, when it became part of the Roman province of Asia. From AD 1207 to 1566 it was under the protection of Venice, falling to Turkey in the latter year. It became part of Greece in 1829. Pop. (1991) 8,731.

Andros, Sir Edmund (b. Dec. 6, 1637, London, Eng.—d. Feb. 24, 1714, London), English administrator in North America who made an abortive attempt to stem growing colonial independence by imposing a kind of supercolony, the Dominion of New England.

Andros grew up as a page in the royal household, and his fidelity to the crown during its exile after the English Civil Wars was rewarded in 1674 by his appointment as governor of New York and New Jersey. (He was also knighted in 1678.) Although the mother country regarded him as an able and conscientious administrator, the colonists considered him both arrogant and arbitrary, and he was recalled in 1681.

Andros returned to America in 1686 as governor of the Dominion of New England, which included the jurisdiction of all the New England colonies and later of New York and New Jersey as well. Andros' imposition of Episcopalian worship in the Old South Meetinghouse in Boston, his vigorous enforcement of the Navigation Acts, his requirement that landholders take out new land patents, and his limitations upon town meetings and rights of local taxation all aroused sharp resentment in colonial America. When news of the overthrow of James II (1688) reached Boston, the colonists revolted, deposing Andros and imprisoning him. Returned to England, he was tried and immediately released. He later served as governor of Virginia (1692), Maryland (1693–94), and the island of Guernsey (1704–06).

Andros Island, largest island of The Bahamas, 25 miles (40 km) west of New Providence island and about 125 miles (200 km) east-southeast of Florida, U.S. A flat, heavily forested island, Andros extends about 100 miles (160 km) from north to south and spans about 45 miles (72 km) from east to west at the widest point. Although the island has a distinct outline, it is highly fragmented with many bays, inlets, lakes, and channels and is technically an archipelago. Just off the east coast is one of the largest barrier reefs in the world. Andros has only a small population and only moderate tourism, and the people tend to live in scattered settlements, the chief towns being Nicolls Town (Nicholls Town), Andros Town, and Kemps Bay, all on the east coast. Fruit and vegetable agriculture and fishing are the island's economic mainstays. A batik industry exists at Andros Town. Area 2,300 square miles (5,957 square km). Pop. (1990) 8,187.

Androsoggin River, river in northeastern New Hampshire and southern Maine, U.S. It flows south from Umbagog Lake to Gorham, N.H., east to Jay, Maine, and then south again

to the Atlantic Ocean. In its 175-mile (280-kilometre) course, the river descends more than 1,245 feet (379 m), the two steepest drops occurring at Berlin, N.H., and at Rumford, Maine. The major communities along the river include Auburn and Lewiston, Maine. The Androsoggin (an Algonquian word meaning "fish-curing place") is known for its fishing, hunting, and boating facilities.

Andrusovo, Truce of, Polish **ANDRUSZOW** (Jan. 30 [Feb. 9, New Style], 1667), long-lasting treaty that ended the Thirteen Years' War (1654–67) between Russia and Poland for control of Ukraine. In 1654 the Russian government accepted the Pereyaslav Agreement, a proposal to annex Ukraine made by the hetman (military leader) of the Zaporozhian Cossacks, Bohdan Khmelnytsky, who had led a revolt in Ukraine against Polish rule (1648–54). That agreement precipitated war between Poland and Russia. During the war, control of Ukraine shifted back and forth many times.

In 1664 peace negotiations began. Although Polish military achievements and Russian exhaustion gave Poland a negotiating advantage, the outbreak of a new rebellion forced the Poles to accept terms favourable to Russia. According to the truce, Ukraine was divided along the Dnieper River; Russia received the eastern portion of Ukraine, the city of Kiev, and the provinces of Smolensk and Seversk. The truce was confirmed by a treaty concluded in 1686.

Andrzejewski, Jerzy (b. Aug. 19, 1909, Warsaw, Pol., Russian Empire—d. April 19, 1983, Warsaw), Polish novelist, short-story writer, and political dissident noted for his attention to moral issues important in 20th-century Poland and for his realistic fiction.

Born into a middle-class family, Andrzejewski studied Polish language and literature at the University of Warsaw. The stories published in his first book, *Drogi niewykłone* (1936; "Unavoidable Ways"), originally appeared in a right-wing periodical, with which he soon severed relations. That volume was followed by the novel *Ład serca* (1938; "Heart's Harmony"), in which Andrzejewski tried to find in Roman Catholic teachings solutions to the problems of contemporary life. During the German occupation of World War II, he participated in the Polish underground.

After World War II Andrzejewski wrote *Noc* (1945; "Night"), a collection of wartime stories, and, together with Jerzy Zagórski, a satirical drama, *Święto Winkelrida* (1946; "Winkelried's Feast"). Contemporary political problems are projected in *Papiół i diament* (1948; *Ashes and Diamonds*; filmed 1958), translated into 27 languages and generally considered his finest novel. It presents a dramatic conflict between young Polish patriots and the communist regime during the last days of World War II.

In 1949 Andrzejewski joined the Communist Party, but in 1956 he gave up membership and established himself as one of the party's principal critics, both in his creative writings and in his activities. In 1976 he became one of the cofounders of the Workers' Defense Committee (KOR), from which eventually grew the anticommunist trade union Solidarity, outlawed in 1981. Andrzejewski also coedited *Zapis* (1977–81), a literary magazine publishing dissident writers. His *Ciemności kryją ziemię* (1957; *The Inquisitors*) and *Bramy raj* (1960; *The Gates of Paradise*) present modern problems disguised as historical novels, while *Apelacja* (1968; *The Appeal*) and *Miazga* (1981; "The Pulp") directly address the issues of contemporary society.

Andrzejewski's life and work seem to be emblematic for many Polish intellectuals of his generation—from his ardent Catholicism be-

fore the war to his heroic involvement with the Resistance during the Nazi occupation, through his subsequent skepticism, to his total acceptance of the Marxist ideology after the war, and, finally, to his disillusionment with and open dissent against communism. His short stories and novels, *Ashes and Diamonds* in particular, can be read as a moving testimony to his development. (J.R.K.)

Andújar, city, Jaén provincia, in the *comunidad autónoma* ("autonomous community") of Andalusia, southern Spain, northwest of Jaén city, on the Guadalquivir River. Called Isturgi, or Ilurgia, by the Celto-Iberians, it was besieged and captured by the Roman general Scipio Africanus the Elder (206 BC) during the Second Punic War. Ferdinand III of Castile united the city to Christian Spain in AD 1224. Andújar has fine old mansions and the Gothic Church of Santa María la Mayor, with a 13th-century tower. The area has lead, uranium, and copper mines, cattle ranches, and poultry farms. Its traditional industry is the manufacture of porous jars (*alcarrazas*) from a local clay. Pop. (1998 est.) 38,254.

anechoic chamber, also called FREE-FIELD ROOM, or FREE-SPACE ROOM, sound laboratory so designed as to minimize sound reflections as well as external noise. External sound is excluded by physical isolation of the structure, by elaborate acoustical filters in the ventilating ducts, and by thick masonry walls. Interior surfaces are covered with absorptive material, such as glass fibre or mineral wool in blankets or in horizontal and vertical wedges (see illustration). Ceiling and floor are similarly padded; a thin steel mesh just above the

Auditory localization experiment in an anechoic chamber

floor provides a surface for walking. Sound reflection can be reduced to one part in 1,000 in such a room, thus simulating the acoustical conditions of unobstructed free space.

Anegada Island, one of the British Virgin Islands and the northernmost of the Lesser Antilles, a chain separating the Atlantic Ocean and Caribbean Sea, lying about 80 miles (130 km) east-northeast of Puerto Rico. The island has an area of 15 square miles (39 square km).

Annual rainfall averages a moderate 50 inches (1,275 mm). Unlike the other Virgin Islands, Anegada (Spanish: "Inundated") is fairly flat, being made of coral and limestone with very little subsoil and no water. There are dangerous reefs, and Anegada's waters contain many still-unexplored shipwrecks. Pop. (1991) 200.

Anegada Passage, channel in the West Indies, connecting the Atlantic Ocean with the Caribbean Sea; it is 40 miles (65 km) wide and separates the British Virgin Islands (west) from the Leeward Islands (southeast). It has the greatest depth (more than 7,550 feet [2,300 m]) of any channel in the eastern Caribbean. The passage is one of the two through which subsurface water enters the Caribbean (the other being the Windward Passage).

Aného, formerly ANÉCHO, town, southern Togo, lying on the Gulf of Guinea, near the border of Benin. Founded in the late 17th century by Ane peoples fleeing from Ashanti attacks in Elmina (now in Ghana), Aného developed as a slave port and commercial centre. It was the capital of German Togoland from 1885 to 1887 and of the French occupation from 1914 to 1920. Aného remains an important intellectual centre for Togo, though it has not grown as rapidly as Togo's other major cities. Pop. (1988 est.) 21,000.

Aneirin (fl. 6th century AD), one of five poets renowned among the Welsh in the 6th century, according to Nennius in his *Historia Britonum* (written c. 800). (The other poets are Taliesin, Talhaearn Tad Awen, Blwchbardd, and Cian, whose works are unknown.) Aneirin's reputation rests on a single work, *Y Gododdin*, considered the earliest extant Welsh work, though preserved only in a manuscript known as *The Book of Aneirin*, which dates from about 1250. The language of the poem is direct for the most part, although simile and metaphor are skillfully used, and alliteration and internal rhyme abound. The poem praises the courage and prowess of Aneirin's contemporaries in the army of Mynyddawg Mwynfawr (Mynyddawg the Wealthy) of Caereidyn (near Edinburgh) and consists of a series of sharp characterizations of each hero in the ill-starred expedition of the war band of 300 men sent by their lord Mynyddawg Mwynfawr to recapture the old Roman stronghold of Catraeth (Catterick in North Yorkshire, Eng.) from the Saxons of Deira.

anemia, also spelled ANAEMIA, condition in which the red cells of the blood (erythrocytes) are reduced in number or volume or are deficient in hemoglobin, their oxygen-carrying pigment. There are close to 100 different varieties of anemia, distinguished by the cause, the size and hemoglobin content of the abnormal cells, and the symptoms. Causally, anemia may result from any of the following:

- (1) Chronic or acute blood loss.
- (2) Increased destruction of the red cells (hemolysis). This may be caused by hereditary cell defects, as in sickle-cell anemia, hereditary spherocytosis, or glucose-6-phosphate dehydrogenase deficiency. It may be caused by exposure to hemolytic chemicals (substances causing the release of hemoglobin from the red cells) such as sulfanilamide, primaquine, or naphthalene (mothballs). Or it may be caused by development of antibodies against the red blood cells, as in erythroblastosis fetalis.
- (3) Reduced production of red cells. This may be caused by disorders of the bone marrow, as in leukemia and aplastic anemia. It may be caused by deficiency of one or more of the nutrients, notably vitamin B₁₂, folic acid, and iron, that are necessary for the synthesis of red blood cells. It may be caused by deficiency of certain hormones. Or it may be caused by inhibition of the red-cell-forming processes by certain drugs or by toxins produced by disease, particularly chronic infection, widespread cancer, and kidney failure.

Structurally, the anemias generally fall into the following types: (1) macrocytic anemia, characterized by larger-than-normal red cells (e.g., pernicious anemia); (2) normocytic anemia, characterized by a decrease in the number of red cells, which are otherwise relatively normal (e.g., anemia caused by sudden blood loss, as in bleeding peptic ulcer, most cases of hemophilia, and purpura); (3) simple microcytic anemia, characterized by smaller-than-normal red cells (encountered in cases of chronic inflammatory conditions and in renal disease); and (4) microcytic hypochromic anemia, characterized by a reduction in red-cell size and hemoglobin concentration (frequently associated with iron-deficiency anemia but also seen in thalassemia).

The most noticeable outward symptom of anemia is usually pallor of the skin, mucous membranes, and nail beds. Symptoms of tissue oxygen deficiency include pulsating noises in the ear, dizziness, fainting, and shortness of breath. Compensatory action of the heart may lead to its enlargement and to a rapid pulse rate.

The treatment of anemia varies greatly, depending on the diagnosis. It includes supplying the missing nutrients in the deficiency anemias, detecting and removing toxic factors, improving the underlying disorder with drugs and other forms of therapy, decreasing the extent of blood destruction by methods that include surgery (e.g., splenectomy), or restoring blood volume with transfusion. See also aplastic anemia; equine infectious anemia; pernicious anemia; sickle-cell anemia.

anemometer, device for measuring the speed of airflow in the atmosphere, in wind tunnels, and in other gas-flow applications. Most widely used for wind-speed measurements is the revolving-cup electric anemometer, in which the

Revolving-cup electric anemometer
EB Inc.

revolving cups drive an electric generator. The output of the generator operates an electric meter that is calibrated in wind speed. The useful range of this device is approximately from 5 to 100 knots. A propeller may also be used to drive the generator, as in the propeller anemometer. In another type of wind-driven unit, revolving vanes operate a counter, the revolutions being timed by a stopwatch and converted to airspeed. This device is especially suited for the measurement of low airspeeds.

The fact that a stream of air will cool a heated object (the rate of cooling being determined by the speed of the airflow) is the principle underlying the hot-wire anemometer. An electrically heated fine wire is placed in the airflow. As the airflow increases, the wire cools. In the most common type of hot-wire anemometer, the constant-temperature type, power is increased to maintain a constant wire temperature. The input power to the hot wire is then a measure of airspeed, and a meter in the electrical circuit of the hot wire can be calibrated to indicate airspeed. This device is useful for very low airspeeds, below about 5 miles per hour. The kata thermometer is a

heated-alcohol thermometer; the time it takes to cool is measured and used to determine air current. It is useful for measuring low speeds in studies of air circulation.

A stream of air striking the open end of a tube closed at the other end will build up pressure within the tube. The difference in pressure between the interior of this tube (called a pitot tube) and the surrounding air can be measured and converted to airspeed. Pitot tubes are also used to measure the flow of liquids, particularly in the course of flume studies in fluid mechanics. This anemometer is most useful, however, in strong, steady air streams, such as in wind tunnels and aboard aircraft in flight. With modifications, it can be used to measure supersonic air flow. Another type of pressure anemometer is the Venturi tube, which is open at both ends and of larger diameter at the ends than at the middle. Airspeed is determined by measuring the pressure at the constriction in the tube. Venturi tubes have some applications in industry.

anemone, also called PASQUEFLOWER, or WINDFLOWER, any of about 120 species of perennial plants constituting the genus *Anemone* of the buttercup family (Ranunculaceae). Many colourful varieties of the tuberous poppylike anemone, *A. coronaria*, are grown for the garden and florist's trade. Popular spring-flowering anemones, especially for naturalizing, are *A. apennina*, *A. blanda*, and *A. pavonina*. Other species, such as the Japanese anemone (*A. hupehensis*, or *A. japonica*) are favourite border plants for autumn flowering. Some species whose fruits differ in structure are placed in a separate

section, *Pulsatilla*, often given the rank of genus. Anemones are distributed throughout the world but occur most commonly in woodlands and meadows of the North Temperate Zone. Many varieties are cultivated in gardens for their colourful flowers.

The wood anemone of Europe, *A. nemorosa*, which bears white flowers, causes blistering of the skin and was formerly used as an ingredient in medicines. In North America, wood anemone refers to *A. quinquefolia*, a delicate plant with deeply cut leaves. Windflower, the English version of the Greek-derived *anemone*, refers to the fact that the flowers seem to be blown open by the wind. The term pasqueflower (from Old French *pasque*, Easter) refers to such floral emblems of Easter as *A. patens*, *A. pratensis*, and *A. pulsatilla*.

anemone fish, any of about 12 species of Indo-Pacific fishes constituting the genus *Amphiprion* of the family Pomacentridae (order Perciformes), noted for their association with large sea anemones. Anemone fishes live and shelter among the tentacles of the anemones, swimming in and out unharmed by the stinging cells (nematocysts) that are present on the

Clown fish (*Amphiprion percula*), one of the anemone fishes

A. Bernhaut—Bavaria-Verlag

tentacles and that can be fatal to other fishes. A representative species, common in the Indo-Australian archipelago, is *Amphiprion percula*, also called the clown fish. Bright orange, with three wide, blue-white bands circling the body, it grows to a length of about five centimetres (two inches).

Anencletus, SAINT (pope): see Anacletus, Saint.

Anerio, Felice (b. c. 1560, Rome—d. Sept. 26/27, 1614, Rome), one of the leading Roman composers of his time, who succeeded his master, Palestrina, as composer to the Papal Chapel in 1594. Most of Anerio's early works are secular, but he began to concentrate on sacred music after his appointment as papal composer.

In general, he modeled his style on that of Palestrina, and several of his pieces were for a long time mistaken for those of the celebrated master. His later compositions, however, do not slavishly imitate the Palestrina style but contain many passages of personal expression. Anerio's works include madrigals, both sacred and secular, canzonets, masses, motets, and other sacred music.

anesthesiology, also spelled ANAESTHESIOLOGY, medical specialty dealing with anesthesia and related matters, including resuscitation and pain. The development of anesthesiology as a specialized field came about because of the dangers of anesthesia, which involves the use of carefully graduated doses of strong poisons to deaden pain. (See anesthetic.) In the 19th century, anesthesia in the operating room,

where the surgeon was in command, was relegated to a minor role. Yet gradually physicians and surgeons recognized the need for anesthesiologists, well-trained specialist physicians dedicated full-time to anesthesia, who could extend surgical horizons by permitting operations previously scarcely conceivable and by allowing applications of surgical principles to patients previously considered too ill to withstand either anesthesia or operation. A few physicians were attracted by this opportunity early in the 20th century, but it was not until the mid-1930s that the specialty was officially recognized with the establishment of such medical societies as the American Board of Anesthesiology for certifying appropriately trained physician anesthetists. Today, in virtually every medical school, anesthesiology functions either as an autonomous academic department or as a division of surgery.

Anesthesiology was originally concerned entirely with the administration of general anesthetics, and the anesthesiologist's activities were confined to the operating room. The advent of local anesthetics injected into the fluid surrounding the spinal cord broadened the methods available to provide relief of pain during an operation. The introduction into clinical anesthesia of drugs aimed specifically at relaxing muscles may have facilitated the surgeon's tasks but deprived patients of the ability to breathe spontaneously, thus creating a need for artificial respiratory support during the operation. As a result, anesthesiologists became specialists in respiratory and circulatory physiology, as well as in devices used to support and monitor these systems and in drugs that act upon them. Increasingly complex operations were undertaken, and more critically ill patients, including the very young and the very old, were treated surgically. Because the individualized attention provided to patients in the operating room could not be terminated abruptly upon completion of an operation, recovery rooms, intensive care units, and respiratory care units became necessities. The anesthesiologist came to be a central figure in all these areas.

In general, anesthesiology may now be defined as a practice of medicine dealing with but not limited to: (1) the management of procedures for rendering a patient insensible to pain and emotional stress during surgical, obstetrical, and certain other medical procedures; (2) the support of life functions under the stress of anesthetic and surgical manipulations; (3) the clinical management of the unconscious patient, whatever the cause; (4) the management of problems in pain relief; (5) the management of problems in cardiac and respiratory resuscitation; (6) the application of specific methods of respiratory therapy; and (7) the clinical management of various fluid, electrolyte, and metabolic disturbances. Knowledge of physiology, biochemistry, pharmacology, and clinical medicine are absolutely necessary to the anesthesiologist.

anesthetic, also spelled ANAESTHETIC, agent which produces a local or general loss of sensation, including pain. General anesthesia involves loss of consciousness, usually for the purpose of relieving the pain of surgery. Local anesthesia involves loss of sensation in one area of the body by the blockage of conduction in nerves.

A brief treatment of anesthetics follows. For full treatment, see MACROPAEDIA: Drugs and Drug Action.

Drugs of various kinds have been used for many centuries to reduce the distress of surgical operations. Homer wrote of nepenthe, which was probably cannabis or opium. Arabian physicians used opium and henbane. More recently powerful rum was administered

(Top) Anemone (*Anemone patens*); (bottom) wood anemone (*Anemone quinquefolia*)

(Top) John Kohout from Root Resources—EB Inc. (bottom) Grant Heilman—EB Inc.

freely to British sailors before emergency amputations were carried out on board ship in the aftermath of battle.

In 1799 Sir Humphry Davy, British chemist and inventor, tried inhaling nitrous oxide (laughing gas) and discovered its anesthetic properties, but the implications of his findings for surgery were ignored. By the early 1840s parties had become fashionable in Britain and the United States at which nitrous oxide, contained in bladders, was passed around and inhaled for its soporific effect. It was soon found that ether, which could be carried much more conveniently in small bottles, was equally potent. In the United States several young dentists and doctors experimented independently with the use of nitrous oxide or ether to dull the pain of tooth extractions and other minor operations. In 1845, Horace Wells, an American dentist, attempted to publicly demonstrate the use of nitrous oxide anesthesia for dental extractions. Unfortunately, the demonstration was unsuccessful.

Historians argue about who should be credited with the first use of true surgical anesthesia, but it fell to William Morton, an American dentist, to convince the medical world that general anesthesia was a practical proposition. He administered ether to a patient having a neck tumour removed at the Massachusetts General Hospital, Boston, in October 1846. Crawford Long, an American surgeon, had used ether in his practice since 1842 but did not make his findings public until 1849.

A few weeks after Morton's demonstration, ether was used during a leg amputation performed by Robert Liston at University College Hospital, London. In Britain, official royal sanction was given to anesthetics by Queen Victoria, who accepted chloroform from her physician, John Snow, when giving birth to her eighth child, Prince Leopold, in 1853.

Early anesthetics had unpleasant side effects (often causing vomiting on recovery) and were somewhat hazardous, since the dose needed to produce unconsciousness and full muscle relaxation (so that the surgeon could work unimpeded) was not far short of that which would paralyze the breathing centre of the brain. In addition, the early anesthetics were administered by simple devices consisting of glass or metal containers for sponges soaked in ether or chloroform (which was introduced as an anesthetic in 1847) and allowed no control of dosage.

Modern inhalation anesthetics such as trichlorethylene and halothane have a much wider safety margin and are administered, mixed with oxygen and nitrous oxide, from an anesthetic machine. The anesthetist can control the flow and composition of the gas mixture precisely and, using a tube placed down the trachea (windpipe) after the patient is unconscious, can, if necessary, maintain respiration by mechanical means. Delivering the gas mixture to the lungs through a close-fitting endotracheal tube also prevents accidental inhalation of mucus, saliva, and vomit.

With respiration artificially maintained it is possible to paralyze the muscles with drugs like curare, a neuromuscular blocking agent, so that procedures requiring full muscle relaxation, such as chest and abdominal surgery, can be carried out under light anesthesia.

Many short operations can be carried out under anesthesia produced by injecting an agent such as the barbiturate sodium thiopental (Pentothal) into a vein, either as a single dose or intermittently through a saline drip. Patients are also commonly put to sleep by this method before the administration of an inhalation anesthetic is begun; since it is a distress-free procedure, and unconsciousness occurs smoothly within 10 or 15 seconds of starting the injection.

Local anesthetics work by blocking the passage of impulses along nerves. Cocaine was thus used for eye operations in 1884 by a Viennese surgeon, Carl Koller, acting on the suggestion of Sigmund Freud. A solution of the drug was applied directly to the part to be operated on. Soon it was being injected under the skin to facilitate small, local operations, and it was later successfully used for larger procedures by injecting it into the trunks of nerves supplying a part. Now, synthetic cocaine substitutes are widely used.

Major operations on the lower half of the body can be carried out after injecting a suitable local anesthetic into the fluid-filled space between the spinal cord and its outer membrane coverings (spinal anesthesia). Painless childbirth can be achieved by an epidural block, which involves injecting the anesthetic agent through a fine tube threaded into the space surrounding the tough membrane covering the lower end of the spinal cord, thus dulling the emerging nerves that supply the pelvic organs.

In recent years much interest has been shown in acupuncture anesthesia, whereby apparently painless major operations are carried out after the insertion of acupuncture needles into specified points on the skin. Often an electric current is passed through the needle used. The results of some research into the efficacy of acupuncture have suggested that the stimulation of the peripheral nerves by the needles triggers the release of endorphins, a group of neurochemicals that have pain-killing effects.

aneuploidy (biology): *see* ploidy.

aneurysm, a bulge or enlargement of some point in the wall of a blood vessel (usually an artery) resulting from disease of the vessel wall. Disease or injury can weaken an artery or cause thinning of its walls, which tend to balloon outward from the pressure of the circulating blood, forming a sac. In a typical aneurysm, the two innermost layers of the arterial wall, the tunica intima and tunica media, have ruptured and a blood-filled bulge or sac is formed by the vessel's outermost layer, the tunica adventitia. In a false aneurysm, all three layers have ruptured, and the arterial blood is held in the vicinity only by the surrounding tissues.

Aneurysms may form as a result of arteriosclerosis (thickening of arterial walls), embolism (a blood clot or foreign object that travels through the bloodstream and eventually becomes lodged in an artery), syphilis, physical injury, or congenital weakness of the artery walls. A small aneurysm can exist for many years without causing any symptoms. A popliteal artery aneurysm is easily detected by the affected person because it causes a noticeable, pulsating bulge behind the knee. An aneurysm in this location may lead to a blood clot and a resultant cutoff of circulation to the lower leg (with danger of gangrene) unless circulation is restored by surgery.

The principal artery prone to aneurysms, however, is the aorta, particularly as it descends through the chest and abdomen. The symptoms of aortic aneurysm vary with the size of the defect and its location. If an aortic aneurysm presses against the windpipe and the bronchi, it may interfere with breathing and lead to coughing. Since aneurysms tend to enlarge over time and blood vessel walls tend to weaken with age, there is risk that an aneurysm will eventually burst, or rupture, an event marked by serious, even massive, internal bleeding. The rupture of an aortic aneurysm causes severe pain and results in immediate collapse. The cerebral hemorrhage that accompanies a ruptured aneurysm in the brain is one of the chief causes of strokes.

An aneurysm on a small artery can be treated simply by tying off the affected vessel, whose blood flow is redirected to adjacent ones. The treatment of more serious aneurysms involves

the surgical removal of the diseased section of artery and its replacement with a plastic graft.

Anezaki Masaharu, also called ANEZAKI CHÖFŌ, Anezaki also spelled ANESAKI (b. July 25, 1873, Kyōto, Japan—d. July 23, 1949, Atami), Japanese scholar who pioneered in various fields of the history of religions.

After graduating from Tokyo Imperial University (now the University of Tokyo), Anezaki went to India and Europe for further studies (1900–03). Returning to Japan, he was appointed to the chair of science of religion at Tokyo Imperial University.

Anezaki started his academic career as a student of Indian religions, and Buddhism in particular. Before him, studies in Buddhist scriptures had been conducted mostly from an apologetic point of view; he was one of the first to apply the modern objective, historical method to the study of Buddhism. Working from the conviction that the true spirit of Buddhism must be sought in its initial stage, he attempted text criticism of Pāli and Chinese canons in *Original Buddhism* (1910). He also initiated research in the history of Kirishitan, the specifically Japanese form of Roman Catholic Christianity, during the period it was banned, from the 17th through the mid-19th century. He became increasingly interested in the 15th-century monk Nichiren and published *Nichiren, the Buddhist Prophet* (1916). Anezaki taught and lectured abroad; the outcome of his Harvard University lectures (1913–15) was *History of Japanese Religion* (1930), a standard work.

Anfinsen, Christian B., in full CHRISTIAN BOEHMER ANFINSEN (b. March 26, 1916, Monessen, Pa., U.S.—d. May 14, 1995, Randallstown, Md.), American biochemist who, with Stanford Moore and William H. Stein, received the 1972 Nobel Prize for Chemistry for research clarifying the relationship between the molecular structure of proteins and their biological functions.

Anfinsen received a Ph.D. degree in biochemistry from Harvard University in 1943 and then held various research and teaching positions. He joined the staff of the National Institutes of Health (Bethesda, Md.) in 1950, and he headed the laboratory of chemical biology in the National Institute of Arthritis, Metabolism, and Digestive Diseases from 1963 to 1982. He was a professor of biology at Johns Hopkins University from 1982 until his death. In his Nobel Prize-winning research, Anfinsen ascertained how the enzyme ribonuclease folds to form the characteristic three-dimensional structure that is compatible with its function. His writings include *The Molecular Basis of Evolution* (1959).

Ang, in the Khmer language, a person of royal blood, usually translated "prince" or "princess." For articles on such persons, see the personal name; e.g., for Ang Duong, *see* Duong.

añgā (Pāli and Sanskrit: "limb," or "division"), any of several categories into which Buddhist canonical writings were divided in early times, beginning before the *Abhidhamma* (scholastic) works were added to the canon. The system, based on a combination of form and content, originally categorized types of material within the various texts; later, it was used to classify the texts themselves. The Theravāda and Mahāsaṅghika schools used an ancient ninefold division; a system of 12 categories was the most common division in other schools, especially Mahāyāna.

The nine *añgās* in Pāli, with their Sanskrit counterparts where different, are:

1. *Sutta*, or *sūtra* ("discourse"), sermons or discourses of the Buddha in prose. This category was said to include the *vinaya* (monastic discipline) material. Apart from the *añgā* system, *sutta* is distinguished from *vinaya* (and the prose limitation is dropped).

2. *Geyya*, or *geya* (a technical term meaning mixed prose and verse), *sutta* that incorporates *gāthā* ("verse").

3. *Veyākaraṇa* ("explanation," or "prophecy"), a category into which the whole Pāli *Abhidhamma Piṭaka* ("Basket of Special Doctrine") has been placed, together with miscellaneous works. For the Sarvāstivāda ("Doctrine That All Is Real") school, the Sanskrit category *vyākaraṇa* meant the Buddha's prophecies concerning his disciples.

4. *Gāthā* ("verse"), works in poetic form.

5. *Udāna* ("inspired utterance"), special sayings of the Buddha in prose or verse (also the name of a work in the Pāli *Khuddaka Nikāya* ["Short Collection"]).

6. *Itivuttaka* ("thus it is said"), sayings of the Buddha introduced by these words; many of them comprise a *Khuddaka Nikāya* work with this title. The Sanskrit category *itivṛttaka* comprises stories about past lives of disciples.

7. *Jātaka* ("birth"; see *Jātaka*), tales of former lives of the Buddha.

8. *Abbhutadhamma*, or *adbhutadharma* ("wondrous phenomena"), stories of miracles and supernatural events.

9. *Vedalla* (perhaps meaning "subtle analysis"), teachings in catechetical form, according to the Pāli system. The Sanskrit tradition places here, as *vaipulya*, a number of important Mahāyāna works, including the *Lotus Sūtra*, *Aṣṭasāhasrikā-prajñāpāramitā*, and *Lañkāvatāra-sūtra*.

The 12-fold Sanskrit system adds these categories:

Nidāna ("cause"), a classification for introductory material and historical narratives.

Avadāna ("Noble Deeds"), Buddha's stories of the good deeds in people's former lives and their present results (see *Apadāna*).

Upadeśa ("instruction"), discussions of doctrine—sometimes esoteric doctrine—often in question-and-answer form. The term has also been used for *Abhidhamma* (scholastic section of the canon), for philosophical treatises, for Tantric works, and for commentaries.

Āṅgad, also called LEHNA, or LAHINA (b. 1504, Matte di Sarai, India—d. 1552, Khadur), second Sikh Gurū and originator of the Punjabi script, Gurmukhī, in which many parts of the *Adi Granth*, the sacred book of the Sikhs, are written.

While on a pilgrimage to the shrine of a Hindu goddess, Āṅgad met the founder of the Sikh religion, Gurū Nānak, whom he resolved to follow. Āṅgad was able to give form and a definitive character to the somewhat vague ideals propounded by Gurū Nānak. He was appointed Gurū in 1539 and set up schools to teach youth the regional language, Punjabi, instead of the classical Sanskrit. He was a firm believer in the importance of physical education and emphasized the ideal of a sound mind and a healthy body.

Gurū Āṅgad also promoted an important Sikh institution, the *Gurū ka laṅgar* ("kitchen of the Gurū"), which, with its insistence on commensality, broke down the traditional Hindu caste system.

Angara River, river in southeast central Russia. It is the outlet for Lake Baikal and a

The Angara River at Irkutsk, Russia

major tributary of the Yenisey River, which it joins near Yeniseysk. The river flows for 1,105 miles (1,779 km) across the southern part of the Central Siberian Plateau and drains over 400,000 square miles (1,040,000 square km). It cuts across basalt flows, which cause many rapids and provide great potential for the generation of hydroelectric power. Dams and power stations were completed at Irkutsk (1956) and Bratsk (1964), the latter creating a reservoir of 2,125 square miles (5,504 square km); a third station at Ust-Ilimsk was completed in 1977; and another hydroelectric station and dam at Boguchany, downstream from Ust-Ilimsk, were under construction in the late 20th century. Power is used in the Irkutsk-Cheremkhovo industrial area along the river.

angaria, Roman imperial postal system modeled on that of Achaemenid Persia, probably originally established in the 6th century BC by Cyrus the Great. The name was derived from the Greek form of a Babylonian word meaning a mounted courier, the means used to carry royal dispatches by night and day in all weather.

The *angaria* presumably survived in Hellenistic times and passed down to the Romans. In the Roman system, the supply and maintenance of post horses was a compulsory duty from which the emperor alone could grant exemption; thus, the word came to mean compulsory service.

Angarsk, city, Irkutsk *oblast* (province), southeast central Russia, on the Trans-Siberian Railroad. Founded in 1948, Angarsk grew rapidly as a major centre of oil refining and petrochemicals. The city's industrial products include such goods as synthetic fibres, artificial fertilizers, plastics, boilers, and cement; there are also electro-engineering works and brewing facilities. Petroleum is piped from West Siberian fields to Angarsk's refinery and petrochemical complex. Pop. (1991 est.) 268,500.

angary, in international law, the right of belligerents to requisition for their use neutral merchant vessels, aircraft, and other means of transport that are within their territorial jurisdiction. Generally, the right of *angary* should be applied only in case of pressing need in time of war, and compensation is due to the neutral owner. The right of *angary* has, in effect, come to be extended to cover not only land and sea transport but also any kind of neutral property under the jurisdiction of a belligerent.

The right of *angary* was applied on several occasions during World Wars I and II. Thus, by proclamation of March 20, 1918, the president of the United States took over merchant vessels of Dutch registry lying in U.S. waters. Similar action was taken by Great Britain, France, and Italy. The United States in 1941, though formally still neutral, took over foreign vessels lying idle in its territorial waters but did so under a special right conferred by statute.

It has come to be recognized that the peacetime powers of expropriation grant adequate authority to seize and requisition property under the territorial jurisdiction of a belligerent state without having recourse to the right of *angary*.

Āngby Stone, 11th-century memorial stone found in Uppland, Swed., bearing a runic inscription carved by Asmund Kareson (Osmundus), earliest known professional rune carver in Uppland. The stone is inscribed with a Maltese cross surrounded by two intertwining serpents and bears the message: "Ragnfrid had this stone erected in memory of Björn, her and Kättilmund's son. God and God's Mother help his soul. He fell in Virland [in Estonia]. But Asmund engraved [the stone]."

A replica of the inscription was found on another stone at Frösunda, Swed.

angel, primarily in Western religions (*i.e.*, Zoroastrianism, Judaism, Christianity, and Islām), any of numerous benevolent spiritual beings, powers, or principles that mediate between the realm of the sacred (*i.e.*, the transcendent realm) and the profane realm of time, space, and cause and effect. Comparable beings in Eastern religions include the Hindu avatars and the Buddhist bodhisattvas.

A brief treatment of angels follows. For full treatment, see *MACROPAEDIA: Doctrines and Dogmas, Religious*.

Functioning as messengers or servants of the deity (the term *angel* derives from the Greek word for "messenger") or as guardians of individuals or nations, angels have been classified into ranks or hierarchies by theologians or philosophical thinkers of the major Western religions, of sects that have become religions in their own right (for example, Druze, a religion that developed from Islām), and of syncretistic movements (for example, Gnosticism, a religious dualistic-belief system that incorporated Jewish, Christian, Iranian, and Hellenistic religious concepts and that viewed matter as evil, the spirit as good, and salvation as being achieved by means of esoteric knowledge, or gnosis).

The number of such celestial beings in the rankings—often 4, 7, or 12—was generally based on the theory of planetary spheres in Hellenistic or Iranian astrology or on the hierarchy derived from Oriental monarchical government. In Zoroastrianism, a religion founded by the 6th-century-BC Persian reformer Zoroaster, the *amesha spentas*, or bounteous immortals, of Ahura Mazdā, the Good Lord, are arranged in a hierarchy of seven: Spenta Mainyu (the Holy Spirit), Vohu Manah (Good Mind), Asha (Truth), Armaiti (Right Mindedness), Khshathra Vairya (Kingdom), Haurvatāt (Wholeness), and Ameretāt (Immortality).

In Judaism, the hierarchy of angels—often called in the Old Testament the "hosts of heaven" or the "company of divine beings"—is not strictly defined. In postbiblical Judaism—especially in apocalyptic literature, which describes God's dramatic intervention in history—seven angels, sometimes called archangels, lead the heavenly hosts that in the Talmud (an authoritative compendium

of Jewish law, lore, and commentary) are viewed as countless. These seven, noted in the noncanonical *First Book of Enoch* (chapter 20), are: Uriel (leader of the heavenly hosts and guardian of *sheol*, the underworld); Raphael (guardian of human spirits); Raguel (avenger of God against the world of lights); Michael (guardian of Israel); Sariel (avenger of the spirits, "who sin in the spirit"); Gabriel (ruler of paradise, the seraphim, and the cherubim); and Remiel, also called Jeremiel (guardian of the souls in *sheol*). Of these, two (Michael and Gabriel) are mentioned in the Old Testament and two others (Raphael and Uriel) in the Apocrypha, a collection of noncanonical works. In rabbinic literature, angels are classified into two basic groupings: higher and lower. Included among the higher group are the cherubim and seraphim, winged guardians of God's throne or chariot, and the *ofannim* (Hebrew: "wheels"), all of which are noted in the Old Testament. Among the sectarians associated with the Dead Sea Scrolls, the higher angels include the angels of light, darkness, destruction, and holiness.

Christianity developed a hierarchy of angels based on the Judaic tradition. In addition to angels, archangels, seraphim, and cherubim, five other spiritual angelic groups—named in the letters of Paul in the New Testament—were accepted in the church by the 4th century: virtues, powers, principalities, dominions, and thrones. Together they made up a hierarchy or choir of angels. As objects of devotion, special attention has been given to the archangels Michael, Gabriel, and Raphael in the Roman Catholic and Eastern Orthodox churches.

Inheriting concepts of angelology from Judaism and Christianity, Islām also developed a hierarchy of angels. In a descending order of importance are: the four throne bearers of Allāh (*hamalat al-'arsh*), symbolized by a man, a bull, an eagle, and a lion in Islāmic legend (which drew from the imagery of the Revelation to John in the New Testament); the cherubim (*karūbiyūn*), who praise Allāh; four archangels (Jibrīl, or Gabriel, the revealer; Mikāl, or Michael, the provider; 'Izrā'īl, the angel of death; and Isrāfil, the angel of the Last Judgment); and lesser angels, such as the *hafazah*, or guardian angels.

Hierarchies of celestial or spiritual beings also were developed among various religions that arose out of the major Western religions, such as the Druzes, and among syncretistic religions, such as Gnosticism, which combined elements of Jewish, Greek, and Christian traditions, and Manichaeism, a dualistic religion that was founded by the 3rd-century-AD Persian reformer Mani. Such religions usually incorporated into their hierarchical concepts aspects of emanation theories, such as aeons or Archons, or of astrology, such as the signs of the zodiac. See also aeon; Archon.

Angel Falls, Spanish SALTO ÁNGEL, also called SALTO CHURÚN MERÚ, waterfall in the Guiana Highlands in Bolívar state, southeastern Venezuela, on the Churún River, a tributary of the Caroní, 160 miles (260 km) south-east of Ciudad Bolívar. The highest waterfall in the world, the cataract drops 3,212 feet (979 m) and is 500 feet (150 m) wide at the base. It leaps from a flat-topped plateau, Auyán-Tepuí ("Devils Mountain"), barely making contact with the sheer face. The falls, discovered in 1935, were named for James Angel, an American adventurer who crash-landed his plane on a nearby mesa in 1937. Because of the dense

jungle surrounding the falls they are best seen from the air.

Angel of Death: see Mengele, Josef.

Angela MERICI, SAINT (b. March 21, 1470/74, Desenzano, republic of Venice [Italy]—d. Jan. 27, 1540, Brescia; canonized May 24, 1807; feast day January 27), founder of the Ursuline (*q.v.*) order, the oldest order of women in the Roman Catholic church dedicated to teaching.

Orphaned young, she went to Salò to live in the home of an uncle. Later she joined the Third Order of St. Francis. At the age of 20 she returned to Desenzano, where she gathered about her a group of girls who taught the catechism to the children of the village.

In 1506, while praying in the fields of Brudazzo, Angela had a vision in which she was told that she would found a society of virgins at Brescia. The citizens of Brescia came to regard her as a prophet and a saint.

On Nov. 25, 1535, at Brescia, Angela and 28 companions consecrated themselves to God by a vow of virginity, and the Company of St. Ursula was born. Angela drew up her rule in 1536, which provided for the Christian education of girls in order to restore the family and, through the family, the whole of Christian society. She was unanimously elected superior of the company in 1537. Before her death she dictated her *Testament and Souvenirs*, which contain her counsels to her nuns; they insist on interest in the individual, gentleness, and the efficacy of persuasion over force.

Angela is often celebrated as a woman of foresight and courage who enjoined her successors to make changes according to the needs of the time.

Angeles, chartered city, central Luzon, Philippines. The city lies on the principal north-south highway and railway lines 50 miles (82 km) north of Manila. Angeles is the site of Angeles University (founded 1962), a Roman Catholic seminary, and several other colleges. Once known as the "city of the dollar," Angeles had an economy fueled by its proximity to the American-run Clark Air Base, which was responsible for the rapid growth of the city by providing substantial employment, housing, and business opportunities. With the eruption of Mount Pinatubo in 1991 and the subsequent decision by the U.S. government to abandon the ash-covered air base, the city's future became uncertain. Inc. city, 1963. Pop. (1990 prelim.) 236,000.

Ángeles, Victoria de los, original name VICTORIA LÓPEZ CIMA (b. Nov. 1, 1923, Barcelona, Spain), Spanish soprano known for her interpretations of Spanish songs and operatic parts and for the timbre of her voice.

Of a musical family, she sang and played guitar before studying piano and voice at the Conservatorio del Liceo in Barcelona. There she performed in concert and in 1945 made her opera debut as the Countess in Wolfgang Amadeus Mozart's *Le nozze di Figaro*. In 1947, after winning first prize in an international competition in Geneva, she gave concert and opera performances throughout Europe. In 1950 she had highly successful debuts at Covent Garden, London, as Mimi in Giacomo Puccini's *La Bohème*; at La Scala, Milan, in the title role of Richard Strauss's *Ariadne auf Naxos*; and at Carnegie Hall, New York City, in recital. Her debut at the Metropolitan Opera the following year was as Marguerite in Charles Gounod's *Faust*. An exceptionally versatile artist, she made many recital tours.

angelfish, any of various unrelated fishes of the order Perciformes. The angelfishes, or scalares, popular in home aquariums are members of the genus *Pterophyllum* and the cichlid (*q.v.*) family. They are thin, deep-bodied fishes with elongated dorsal, anal, and pelvic fins. Depending on the authority, one to three species may be recognized: *P. scalare*, *P. eimekei*, and *P. altum*. Angelfishes are native to the freshwaters of South America and may grow to a length of about 15 cm (6 inches). They are commonly silvery with vertical dark markings but may be solid or partially black. They are carnivorous and take care of their eggs and young.

An aquarium angelfish (*Pterophyllum*)

bodied fishes with small mouths and rather rough scales; the largest grows about 46 cm (18 inches) long. These angelfishes are distinguished from the butterfly fishes by a sharp

spine on each cheek. These angelfishes feed on algae and various marine invertebrates. The family, which includes fewer than 100 species, is represented in both the Atlantic and the Indo-Pacific. In many species, colouring of the young differs greatly from that of adults.

Among the better-known species are the black and gold angelfish (*Centropyge bicolor*) of the Indo-Pacific; the French angelfish, *Pomacanthus paru* (or *P. arcuatus*), a black and yellow species of the Atlantic; and the queen angelfish (*Holocanthus ciliaris*), a blue and yellow fish of the Atlantic.

angelica, large genus of aromatic herbs of the family Apiaceae (Umbelliferae). The roots and fruit of the Eurasian species, *Angelica*

Angelica (*Angelica archangelica*)

archangelica, yield angelica oil used to flavour liqueurs and in perfumery, while the tender shoots are used in making certain kinds of aromatic sweetmeats; tea made from the roots and leaves is a traditional medicine for respiratory ailments. In the Faroe Islands and in Iceland, where the plant grows abundantly, it is considered a vegetable. The British species, *A. sylvestris*, is a tall perennial herb with large bipinnate leaves and large compound umbels of white or purple flowers. The common name alexanders is applied to *A. atropurpurea* in the United States.

angelica, sweet, fortified dessert wine said to have originated near Los Angeles, for which it is named. Angelica is one of the oldest California wines; it was probably originally made from the mission grape, a European variety brought to California in the 18th century by Spanish padres. Early versions of angelica were occasionally extraordinary; some that survived from the 1870s remained superb more than a century later.

shrub or tree, of the ginseng family (Araliaceae), that can reach a height of 15 m (about 50 feet). Its leaves are large, with leaflets arranged feather-fashion and often prickly. The angelica tree is native to low-lying areas from Delaware to Indiana, south to Florida, and as far west as Texas.

Angelico, FRA ("Brother"), original name GUIDO DI PIETRO, also called GIOVANNI DA FIESOLE (b. c. 1400, Vicchio, republic of Florence [Italy]—d. Feb. 18, 1455, Rome), Italian painter, one of the greatest 15th-century painters, whose works, within the framework of the early Renaissance Florentine style, embody a serene religious attitude and reflect a strong classical influence. Most of his early work consists of murals that he painted for the Monastery of San Marco in Florence while he was in residence there. About 1450, near the end of his life, he produced a cycle of 35 paintings for the doors of a silver chest in the sanctuary of the Church of Santissima Annunziata, also in Florence.

San Domenico period. Baptized Guido di Pietro, he gained a reputation as a painter under this name by 1417. In that year he became associated with a miniaturist of the late Gothic tradition, Battista Sanguigni, who was later his assistant.

Sometime between the years 1420 and 1422, he became a Dominican monk and resided in the Monastery of San Domenico at Fiesole, there taking the name of Fra Giovanni da Fiesole. At Fiesole, he was probably influenced by the teachings of Giovanni Dominici, the

vast landscape dominated by a varicoloured hill town. It is perhaps an imaginative evocation of Cortona, where Fra Angelico spent some time and where important works of his are to be found. Against that background are sharply outlined human figures in interconnected groups; their features are so delicately traced that attempts have been made to identify them as portraits. These arrangements of figures attest to Angelico's deep knowledge of the formalism that characterized the art of the early Renaissance.

Two strands were interwoven in Angelico's life at Fiesole: the pious life of a monk and continuous activity as a painter. Vasari described him as "saintly and excellent," and, not long after his death, he was called *angelico* ("angelic") because of his moral virtues. This subsequently became the name by which he is best known, often preceded by the word *beato* ("blessed").

Angelico did not remain absorbed in prayer in his monastery, however; he knew and followed closely the new artistic trends of his time, above all the representation of space by means of perspective. In works such as the large "Last Judgment" and "The Coronation of the Virgin," for example, the human figures receding toward the rear themselves create a feeling of space similar to that in the paintings of Angelico's great Florentine contemporary Masaccio. The earliest work by Angelico that

"The Annunciation," fresco by Fra Angelico, 1438-45; in the Museum of San Marco, Florence

Scala/Art Resource, New York City

militant leader of the reformed Dominicans; the writings of Dominici defended traditional spirituality against the onslaught of humanism.

Angelico was also influenced by his fellow monk St. Antoninus Pierozzi, who became the archbishop of Florence when Fra Angelico refused the post and who may have consolidated Angelico's faith. It is believed that Antoninus also may have inspired some of Angelico's compositions.

Angelico was probably trained by the greatest painter and miniaturist of the Gothic tradition, Lorenzo Monaco, whose influence may be seen in the clear, painstaking delicacy of execution and the vibrant luminosity that seem to spiritualize the figures in Angelico's paintings. These qualities are apparent in two small altarpieces, "Madonna of the Star" and "The Annunciation."

Angelico's "Deposition" for Santa Trinita in Florence was once attributed to Lorenzo Monaco, who had begun it before he died in 1425. Monaco had divided it into a triptych and executed the pinnacles. Angelico, however, made it a unified altarpiece with a

can be dated with certainty is a triptych of huge dimensions that he painted for the linen merchants' guild (or Arte dei Linaiuoli; hence its name, the "Linaiuoli Altarpiece"); it is dated July 11, 1433. Enclosed in a marble shrine designed by the Florentine sculptor Lorenzo Ghiberti, this altarpiece represents the Virgin and Son facing forward, monumentally, and, surrounding them in a minor key, charming angels, developing the motif of the "Madonna of the Star." The group has affinities with the Florentine *Maestàs* (i.e., Madonna and child enthroned in majesty) of the 14th century, but the influence of Masaccio may be seen in the formalism of the construction, extending in a somewhat strained manner to the four saints painted on the two folding shutters. Angelico finished the work with a predella, or narrow strip of paintings at the bottom: this group of paintings includes "The Adoration of the Magi" and "The Martyrdom of St. Mark," which are lucid and compact in their narrative and have a strictly defined perspective, a technique that is even more effective in the small painting depicting the naming of John the Baptist.

In 1436, Angelico was commissioned to paint an altarpiece for the Brotherhood of Santa Maria della Croce al Tempio, which he completed by December of that year. In the serene "Lamentation," he executed figures in silent contemplation surrounding the dead Christ. Angelico was inspired by a famous painting by the 14th-century master Giotto (now in the Uffizi), but he expanded the subject to include more figures in a more complex arrangement, and he set them within a melancholy landscape, extending across the long walls of Jerusalem, with a leaden overhanging sky. In this painting Angelico included figures from sacred tradition and persons who had existed historically, probably to point up the historical continuity of devotion to the Redeemer.

Also in the 1430s, Angelico painted one of the most inspired works of the Florentine Renaissance, "The Annunciation," now in the Diocesan Museum of Cortona, an altarpiece significantly superior to his two other paintings on the same subject. It shows the Garden of Eden with Adam and Eve being driven out by the Angel, yet also under the sway of the radiant messenger and pure maiden who are portrayed in the space of a Renaissance-style portico. The predella is skillfully divided into stories of the Virgin Mary, naturalistically portrayed, especially the Visitation, which has a realistic panorama. Angelico always followed reality closely, even when he used a miniaturist technique. Occasionally, he resorted to medieval techniques, such as a gold background, in deference to the taste of those who commissioned the work, but his figures still emerge quite distinctly from the panels, in the Renaissance manner, revealing the painter's increasingly sure and harmonious pictorial idiom. Angelico's "Annalena Altarpiece," also of the 1430s, is, so far as is known, the first *sacra conversazione* (i.e., "sacred conversation," a representation of the Holy Family) of the Renaissance.

Years at the monastery of San Marco. Angelico remained in the Fiesole monastery until 1439, when he entered the monastery of San Marco in Florence. There he did most of his work as a mural painter. San Marco had been transferred from the Sylvestrine monks to the Dominicans in 1436, and the rebuilding of the church and its spacious monastery began around 1438, from designs by the Florentine architect and sculptor Michelozzo. The construction was generously subsidized by the Medici family. Angelico was commissioned around 1438 by Cosimo de' Medici the Elder to execute the altarpiece, for which he again painted a *sacra conversazione*. When the church was consecrated at Epiphany in 1443, the altarpiece must have dominated the place of worship. Angelico portrayed the Virgin and child raised high on a throne, with saints on either side receding into space; among them are the two patron saints of the Medici, Cosmas and Damian. This work, one of the most compelling Fra Angelico ever created, ends in a dense grove of cypresses, palms, and pines against a deep but toneless sky. His figures seem cleansed of any human passion and to have supreme serenity of spirit. A predella, showing eight little legends of the two Medicean saints separated by a Pietà (Virgin Mary holding the body of Christ), completed the work. Unfortunately, these paintings are now scattered among various museums. The narrative in all the scenes is more organized and simplified than in his previous work, with creative touches that he was later to carry forward in his mural painting.

On the walls of the monastery of San Marco in Florence are the paintings that mark the high point of Angelico's career. In the chapter hall, he executed a large "Crucifixion" that seems akin to the "Moralities" of the 14th cen-

tury, which urged detachment from worldly vanities and salvation through Christ alone. In addition to the three crucified figures against the sky, Angelico painted groups of ritual figures, rhythmically arranged, with a chorus of martyrs, founders of religious orders, hermits, and defenders of the Dominican order (whose genealogical tree is depicted beneath this striking scene), as well as the two Medicean saints. Thus, in the comprehensiveness of this work, Fra Angelico developed a concept that was barely suggested in his earlier altarpieces.

He portrayed the exaltation of the Redeemer in many other paintings in the monastery's first cloister and in its cells. In one corridor he executed an Annunciation that broadened the pattern of his earlier one in Cortona and, beyond it, a *sacra conversazione*, bathed in lucid light. In the cells, he proclaimed devotion to Christ crucified in at least 20 examples, all related to monastic life. The pictorial work in these narrow spaces is intricate, probably the work of numerous hands directed by the master, including Benozzo Gozzoli, the greatest of Fra Angelico's disciples, and Zanobi Strozzi, another pupil better known as a miniaturist, as well as his earliest collaborator, Battista Sanguigni. The hand of Fra Angelico himself is identifiable in the first 10 cells on the eastern side. Three subjects merit particular attention: a Resurrection, a coronation of the Virgin, and, especially, a gentle Annunciation, presented on a bare white gallery, with St. Peter Martyr in prayer, timidly facing the group, his coloured habit contrasting with the delicate two tones of pink in the garments of the Virgin and the Angel. The cells, originally hidden from public view because of monastic vows of reclusion, reveal the secret joy of the painter-monk in creating figures of purity to move his fellow monks to meditation and prayer. The images in these paintings are the lyrical expressions of a painter who was also their prior.

Roman period. At the end of 1445 Fra Angelico was called to Rome by Pope Eugene IV, and he remained there until about 1450. In the summer of 1447, however, he had undertaken to decorate the chapel of San Brizio in the cathedral of Orvieto. Angelico's assistants, above all, Gozzoli, worked closely with him on two canvases, crowded with figures, in this chapel. These canvases of Christ the Judge, amid the hierarchy of angels, and the chorus of the prophets, respectively, were only partially executed by Angelico; they were continued more than 50 years later by Luca Signorelli.

In Rome, the frescoes that Angelico executed in a chapel of St. Peter's (c. 1446-47), in the chapel of the Sacrament in the Vatican (not before 1447), and in the studio of Pope Nicholas V (1449) have all been destroyed. But the Vatican still possesses his decorative painting for the Chapel of Niccolò V. There, he painted scenes from the lives of Saints Stephen and Lawrence, along with figures of the Evangelists and saints, repeating some of the patterns of the predella on his altarpiece of San Marco. The consecration scene of St. Stephen and that of St. Lawrence are both set in solemn cathedral interiors, and the almsgiving of St. Lawrence is set against the background of a temple. In this scene particularly, Angelico imbued the poor and afflicted who surround the deacon-saint with a serenity that purifies them and illuminates them with an inner light, rendering them equals of the blessed figures on the altarpieces. At the same time, the organization of these works and the rendering of architecture in them mark the culmination of his development as a Renaissance artist.

Around 1450 Fra Angelico returned to Florence, where, still a monk, he became prior of the monastery of San Domenico in Fiesole (1450-c. June 1452). His most notable work of this time was the cycle of 35 paintings of

scenes from the life of Christ and other subjects, for the doors of a silver chest in the sanctuary of the Church of Santissima Annunziata in Florence. These works, which have been extensively repainted, are probably distant echoes of the destroyed paintings in the Chapel of Niccolò V. Although the authenticity of these works is disputed, the "Massacre of the Innocents," "Flight into Egypt," and "Presentation in the Temple" seem to be Angelico's because of the bright spontaneity of the slender figures, as well as the spatiality of the surroundings and the landscape. Such traits derived from the artist's vast experience in mural painting. In most of these little pictures, however, there is a kind of disconnectedness and weariness, indicating the hand of pupils whose art was a far cry from Fra Angelico's ineffable poetry. There is still a certain monumental tone in the late altarpiece he executed in the monastery of Bosco ai Frati in the Mugello (now in the Museum of San Marco, Florence). With the completion of this altarpiece and several other minor works, Fra Angelico's fertile artistic labours drew to a close.

In 1453 or 1454, Fra Angelico again went to Rome, where he died in the Dominican monastery in which he had stayed during his first visit to Rome. It was close by the church of Santa Maria della Minerva, where his tomb remains an object of veneration.

Assessment. In addition to the influence he had on his followers, Fra Angelico exerted a significant influence in Florence, especially between 1440 and 1450, even on such an accomplished master as Fra Filippo Lippi. As a monk, Fra Angelico was lauded in writings of the 15th century and later, some of which bestowed a legendary halo on him. As a painter, he was acclaimed as early as 1438 by the contemporary painter Domenico Veneziano. Giorgio Vasari, in his section on Angelico in *Lives of the Most Eminent Italian Painters, Sculptors and Architects*, was inaccurate in his biographical data but correctly situated Fra Angelico in the framework of the Renaissance. Vasari characterized him in terms that remained standard until the end of the 18th century, when writers of the Neoclassical period, using judgments of a philosophical and didactic nature, placed him out of his time and even in the 14th century, thus making him an artist of transition. Almost all modern art critics, however, place him again within the framework of the Renaissance. With classical measure, Fra Angelico embodied a deeply religious attitude. (M.Sal.)

BIBLIOGRAPHY. John Pope-Hennessy, *Fra Angelico*, 2nd ed. (1974).

Angell, Sir Norman, original name RALPH NORMAN ANGELL-LANE (b. Dec. 26, 1873, Holbeach, Lincolnshire, Eng.—d. Oct. 7, 1967, Croydon, Surrey), English economist and worker for international peace who was awarded the Nobel Peace Prize for 1933.

After an education in France, London, and Geneva, he spent several years (1890-98) in the United States, working as a cowboy, a prospector, and finally a journalist for the *St. Louis Globe-Democrat* and *San Francisco Chronicle*. Upon his return to Europe, other editorial posts followed, notably editorship of *Galignani's Messenger* (1899-1903) and *Foreign Affairs* (1928-31).

Angell's most famous work, *The Great Illusion* (1910), translated into more than a score of languages, tried to establish the fallacy of the idea that conquest and war brought a nation great economic advantage and insured its living space and access to markets, trade, and raw materials. *The Great Illusion*, 1933 (1933) explored the economic developments and ideas of the 23 years since publication of the first edition. Angell's literary output was great, producing sometimes more than one book a year. He also invented the Money

Game, a series of card games using paper money to teach the fundamentals of currency and credit.

Angelou, Maya, original name MARGUERITE JOHNSON (b. April 4, 1928, St. Louis, Mo., U.S.), African American poet whose several volumes of autobiography explore the themes of economic, racial, and sexual oppression.

Although born in St. Louis, Angelou spent much of her childhood in the care of her paternal grandmother in rural Stamps, Ark. Raped at the age of eight by her mother's boyfriend, she went through an extended period of muteness. This early life is the focus of Angelou's first autobiographical work, *I Know Why the Caged Bird Sings* (1970). Subsequent volumes of autobiography include *Gather Together in My Name* (1974), *The Heart of a Woman* (1981), and *All God's Children Need Traveling Shoes* (1986).

In 1940 Angelou moved with her mother to San Francisco and assumed her professional name while working there as a dancer. The literary talent recognized and nurtured by an early mentor led Angelou in the late 1950s to New York City, where she found encouragement from the Harlem Writers' Guild. She lived in Egypt and Ghana for several years during the 1960s. After returning to California in 1966, she began writing screenplays, including *Georgia, Georgia*; produced in 1972, it was the first feature film adapted from a story by an African American woman. She also acted in movies and in 1998 made her directorial debut with *Down in the Delta*.

Angelou's poetry, collected in such volumes as *Just Give Me a Cool Drink of Water 'fore I Diie* (1971), *And Still I Rise* (1978), and *I Shall Not Be Moved* (1990), draws heavily on her personal history but employs the points of view of various personae. She also wrote a book of meditations, *Wouldn't Take Nothing for My Journey Now* (1993), and children's books that include *Life Doesn't Frighten Me* (1998). In 1981 she became a professor of American studies at Wake Forest University in Winston-Salem, N.C.

Angelus FAMILY, family that produced three Byzantine emperors. The Angelus family was of no particular significance until the 12th century, when Theodora, youngest daughter of the emperor Alexius I Comnenus, married Constantine Angelus of Philadelphia (in Anatolia). Numerous members of the family then held high positions under Manuel I Comnenus and were involved in an aristocratic revolution that in 1185 overthrew Andronicus I Comnenus and placed Isaac II Angelus on the throne. Isaac and his brother Alexius III, who deposed and blinded Isaac in 1195, were among the least competent of all Byzantine rulers.

The despots of Epirus and Thessaly, who saved much of northern Greece from Western conquest after 1204 and whose dynasty survived until 1318, were direct descendants of Constantine Angelus and Theodora. One of the last prominent members of the family was John Angelus, who was appointed governor of Thessaly in 1342.

Angelus SILESIVS, original name JOHANNES SCHEFFLER (b. December 1624, Breslau, Silesia [now Wrocław, Pol.]—d. July 9, 1677, Breslau), religious poet remembered primarily as the author of *Der Cherubinischer Wandersmann* (1674; "The Cherubic Wanderer"), a major work of Roman Catholic mysticism.

The son of a Lutheran Polish nobleman, Scheffler was court physician to the Duke of Oels in his native Silesia when his readings in the mystics, especially Jakob Böhme, and in the Church Fathers led him to the Roman Catholic church, into which he was received in 1653. After six years as physician to the Holy Roman emperor Ferdinand III, at Vienna, he returned to Breslau and was ordained to the

priesthood in 1661. He was fanatical in his opposition to Protestantism, and he contributed some 55 polemical pieces to a Lutheran-Catholic controversy that was notable even in that day for its harshness.

The first of his poetic works, published in 1657, was *Geistreiche Sinn- und Schlussreime* ("Epigrammatic Verses on the Spiritual Life"), a collection of couplets on various religious truths. It became better known under the title of its second edition, *Der Cherubinischer Wandersmann*. Another collection, *Heilige Seelenlust* ("Holy Joy of the Soul"), contains his religious songs celebrating the union of the soul with God, many of which appear today in both Protestant and Catholic hymnals.

Angelus, Isaac (Byzantine emperor): see Isaac II Angelus.

Angerman River, Swedish ÄNGERMANÄLVEN, river in the *län* (counties) of Västerbotten and Västerorrland, northern Sweden. It rises near the Norwegian border and flows in a winding course for 280 miles (450 km) southeast past Vilhelmina, Åsele, Sollefteå, and Kramfors, emptying into the Gulf of Bothnia a few miles northeast of Härnösand. The Fjäll and Fax rivers, both on its right bank, are its main tributaries. In the plateau region are Lake Vojm (31 square miles [80 square km]) and Lake Flå (43 square miles [111 square km]), both of which help to regulate the river flow. Because of the many falls along the river's route, hydroelectric power stations are numerous. Lumber and pulp mills are found along the river's 20-mile- (32-kilometre-) long navigable estuary.

Ångermanland, landskap (province) in northeastern Sweden. It is bounded on the east by the Gulf of Bothnia, on the south and west by the *landskap* (provinces) of Medelpad and Jämtland, and on the north by those of Lappland and Västerbotten. The northeastern corner of Ångermanland is included for administrative purposes in the *län* (county) of Västerbotten, and the remainder in Jämtland and Västerorrland. One of the traditional *landskap* making up the region of Norrland (*q.v.*), it consists of vast forests and large rivers, such as the Fax and Angerman rivers. The major towns are Härnösand (*q.v.*), Sollefteå, and Örnsköldsvik. Area 7,645 square miles (19,800 square km). Pop. (1994 est.) 154,240.

Angers, city, capital of Maine-et-Loire *département*, Pays de la Loire *région*, western France. Angers is the former capital of Anjou and lies along the Maine River 5 miles (8 km) above the latter's junction with the Loire River, northeast of Nantes. The old city is on the river's left bank, with three bridges crossing to Doutré. Capital of the Andecavi, a Gal-

lic tribe of the state of Andes, the ancient town became Juliomagus under the Romans. The succession of counts of Anjou began in the 9th century, and during the rule of the Plantagenets magnificent monuments were constructed, of which the French Hôpital Saint-Jean (now housing an archaeological museum) is the most striking. The city's massive moated château, whose 17 towers are from 130 to 190 feet (40 to 58 m) high, was built in 1230 on the site of earlier castles; it houses the late 14th-century Apocalypse series of tapestries (woven by Nicholas Bataille). Despite the damage of past wars, particularly World War II, Angers is still rich in medieval architecture. The 12th-13th-century Cathedral of Saint-Maurice retains its original stained glass. The 15th-century Barrault House contains the public library, an art museum, and the complete works of the sculptor Pierre-Jean-David d'Angers, who was born in the city. The prefecture is in the former Saint-Aubin Abbey (11th century), which has Roman arcades. The medieval Universitas Andegavensis was refounded in 1876 as the Catholic Faculty of the West.

The city's traditional industries such as slate quarrying, distilling, rope and cable manufacture, and weaving have been supplemented by electronics, photographic equipment, and elevators. Pop. (1999) 151,279.

Angevin DYNASTY: see Plantagenet, house of.

Angevin empire, the territories, extending in the latter part of the 12th century from Scotland to the Pyrenees, that were ruled by the English king Henry II and his immediate successors, Richard I and John; they were called the Angevin kings because Henry's father was count of Anjou. Henry acquired most of his continental possessions before becoming king of England. By inheritance through his mother (King Henry I's daughter, Matilda), he became duke of Normandy in 1150; he succeeded his father as count of Anjou, Maine, and Touraine in 1151; and in 1152, by marrying Eleanor of Aquitaine, he acquired that duchy, together with Gascony, Poitou, and Auvergne. Brittany, first conquered by Henry I in 1113, was finally brought into the Angevin "empire" when Henry II's son Geoffrey, who had married the heiress of Duke Conan IV, succeeded as duke of Brittany in 1171. Although all these lands were fiefs, held of the king of France, their concentration in one man's hands was a serious threat to the French monarchy, which had direct control of a much smaller area of land. As king of England from 1154, Henry

Angers, France, and the château on the Maine River

had direct rule over all England and southern Wales, and suzerainty over the principality of Gwynedd in northern Wales. In 1171 he annexed Ireland and obtained direct control of the eastern part of the island and nominal control of the remainder. Finally, from 1174 to 1189, William I the Lion, king of Scotland, captured in a skirmish in 1174, was obliged to accept Henry as his overlord.

Henry's plans to divide his "empire" among his sons led to many quarrels and wars, which the French king eagerly fostered. Only Richard and John survived their father's death (1189), and although John was confirmed as lord of Ireland, which he had held since 1177, he was subject to Richard, who otherwise held all his father's possessions. Early in John's reign (1199–1216) the French king Philip II Augustus wrested from him Normandy, Anjou, Maine, and Touraine. By the Treaty of Paris (1259) the English retained only the duchy of Guyenne (a much-reduced vestige of Aquitaine, with Gascony). Its confiscation in 1337, together with an English claim to the French throne, led to the outbreak of the Hundred Years' War, by the end of which England retained in France only Calais, which was finally lost in 1558.

Anghiera, Peter Martyr d': *see* Peter Martyr d'Anghiera.

Angilbert (b. c. 740, Aachen, kingdom of the Franks [now in Germany]—d. Feb. 18, 814, Centula, Picardy [now in France]), Frankish poet and prelate at the court of Charlemagne.

Of noble parentage, he was educated at the palace school at Aachen under Alcuin and was closely connected with the court and the imperial family. In 800 he accompanied Charlemagne to Rome and was one of the witnesses to his will. He was made abbot of Centula (Saint-Riquier), Picardy, in 794. Angilbert's Latin poems show the culture and tastes of a man of the world. A fragment of an epic, probably by him, describes life at the palace and the meeting between Charlemagne and Pope Leo III and earned him the nickname of "Homer" from Alcuin. His shorter poems show skill in versification and present a picture of the imperial circle.

angina pectoris, spasm of pain in the chest, usually brought on by exertion in persons who have diseased coronary arteries. A deep, vise-like pain is felt beneath the breastbone and over the heart and stomach, and it sometimes radiates into the left shoulder and down the inner side of the left arm. A feeling of constriction or suffocation often accompanies the pain, though there is seldom actual difficulty in breathing. In acute cases, the sufferer becomes pale, his pulse is feeble, and he feels that death is imminent. Anginal pain may be quite mild in some cases, but its peculiar qualities can still induce feelings of anxiety in the sufferer.

Attacks of angina can be precipitated by walking or more strenuous exertion, by a fit of anger, fear, or some other stressful emotional state, by exercising after a heavy meal, or simply from exposure to cold or wind. A person stricken with angina is obliged to stop whatever activity he is engaged in and rest, and after three or four minutes the pain subsides as quickly as it began.

Angina is caused by the inability of diseased coronary arteries to deliver sufficient oxygen-laden blood to the heart muscle. The arteries have been narrowed by atherosclerosis (hardening of the arteries), and when insufficient blood reaches the heart, waste products accumulate in the heart muscle and irritate local nerve endings, causing anginal pain.

Attacks of angina are apt to recur following less and less exertion as a person's coronary

artery disease worsens. Angina pectoris is rare in persons under middle age and is much more common in males than in females.

An anginal attack can be relieved by rest or by taking nitroglycerin or other drugs that relax (and thus dilate) the blood vessels. The frequency of attacks can be lessened by the avoidance of emotional stress and by shifting to exercise that is less vigorous. In cases where the narrowing of the coronary arteries appears serious enough to cause a heart attack (myocardial infarction), surgery must be used to widen the passages within the arteries or replace the arteries with unblocked ones from another portion of the body.

angiocardiography, method of following the passage of blood through the heart and great vessels by means of the intravenous injection of a radiopaque fluid, whose passage is followed by serialized X-ray pictures. A thin plastic tube (catheter) is positioned into a heart chamber by inserting it into an artery, usually in the arm, threading it through the vessel around the shoulder, across the chest, and into the aorta (*see* cardiac catheterization). The radiopaque dye is then injected through the catheter. With the use of X ray, the dye can be seen to flow easily through the healthy sections but narrows to a trickle or becomes completely pinched off where lesions, such as fatty deposits, line and obstruct the lumen of blood vessels (characteristic of atherosclerosis). The most frequently used angiographic methods are biplane angiography and cineangiography. In the first method, large X-ray films are exposed at the rate of 10 to 12 per second in two planes at right angles to each other, thus permitting the simultaneous recording of two different views.

In cineangiography, the X-ray images are brightened several thousandfold with photoamplifiers and photographed on motion-picture films at speeds of up to 64 frames per second. When projected at 16 to 20 frames per second, the passage of the opacified blood may be viewed in slow motion. Angiography is used to evaluate patients for cardiovascular surgery. Although it is a valuable tool in assessing some of the more complicated aspects of heart function, it is also one of the most hazardous of all diagnostic procedures; serious reactions to the iodine-containing compounds used, including radiopaque media, are not infrequent, despite continued efforts to develop less harmful materials. *See also* contrast medium.
